The production of copper has shown large increases during the last three years. In 1916 the total copper contents of smelter products credited to Canadian ores and estimated recoveries from ores exported amounted to 119,770,814 lb.; production in 1915 was 100,785,150 lb. Of the total 1916 production 92,763,603 lb. was contained in blister copper and in matte, and 27,007,211 lb. estimated as recovered from ores exported. In addition to the recoveries from domestic ores there was also recovered by British Columbia smelters 5,551,166 lb. of copper from imported ores. An electrolytic copper refinery, installed at Trail, began active operations about Nov. 1 with a capacity of 10 tons of refined copper per day. Exports of copper according to Customs records were: Copper fine in ore, matte, regulus, etc., 124,942,400 lb.; in pigs, bars, sheets, etc., 2,430,400 lb. There were also exports of old and scrap copper amounting to 5,846,600 lb.

The production of nickel in 1916 was, as usual, derived from the ores of the Sudbury district supplemented by the recovery of a small quantity of metallic nickel, nickel oxide and other nickel salts as by-products in the treatment of ores from the silver-cobalt-nickel ores of the Cobalt district. The total production was 82,958,564 lb., as against 68,308,657 lb. in 1915. The total production of matte in 1916 was 80,010 tons containing 44,859,321 lb. of copper and 82,596,862 lb. of nickel. The tonnage of ore smelted (part being previously roasted) was 1,521,689 tons.

Nickel was recovered as a by-product in smelteries at Deloro, Thorold, and Welland, from the silver-cobalt-nickel ores of the Cobalt district, the total nickel contents of nickel oxide, nickel sulphate, and metallic nickel produced being 361,701 lb. The products recovered included 79,360 lb. of metallic nickel, 323,418 lb. of nickel oxide, and 232,450 lb. of nickel sulphate.

The demand for molybdenite resulted in considerable exploration of known occurrences and the development of several properties of considerable promise. The total MoS_2 contents of concentrates produced and shipped during the year was about 159,000 lb., for which the official price paid was 105s. per unit of MoS_2 at Liverpool. A portion of the concentrates was used in the manufacture of molybdic acid, and ferromolybdenum at Orillia, Ont. Ferromolybdenum is also now being made at Belleville, Ont.

The total production of pig iron in 1916, not including the output of ferro-alloys, was, according to complete returns now received, 1,169,257 short tons. The production of ferro-alloys in Canada in 1916, chiefly ferrosilicon, but including also ferrophosphorus and ferromolybdenum, all made in electric furnaces, was 28,628 tons.

The asbestos industry was particularly active during 1916, the value of the production having been the highest on record, though the quantity was slightly exceeded in 1913. The total quantity of asbestos rock sent to mills during the year was 1,822,461 tons, from which was obtained 112,832 tons of fibre, or an average recovery of 6.20%.

Product.	Quantity.
Metallic:—	
Antimony ore (exports), tons*	794
Cobalt, metallic and contained in oxide, etc., lb.	841,850
Copper, lb.	119,770,814
Gold, oz.	926,963
Iron, pig iron Canadian ore, tons	115,691
Iron, ore sold for export, tons	140,608
Lead, lb.	41,593,680
Molybdenite, MoS_2 contents, lb.	159,000
Nickel, lb.	82,958,564
Platinum, oz.	15
Silver, oz.	25,669,172
Zinc, lb.	23,515,030
Non-metallic:—	
Actinolite, tons	250
Arsenic, white, tons	2186
Asbestos, tons	136,016
Asbestic, tons	18,500
Chromite, crude ore,† tons	27,030
Coal, tons	14,461,678
Corundum, tons	67
Felspar, tons	19,166
Fluorspar, tons	1284
Graphite, tons	3971
Gritstones, tons	3328
Gypsum, tons	341,618
Magnesite, tons	55,413
Manganese, tons	979
Mica, tons	914
Mineral pigments:—	
Barytes, tons	1368
Oxides, tons	8811
Mineral water	—
Natural gas, Million cu. ft.	25,238,568
Peat, tons	300
Petroleum, barrels	198,123
Phosphate, tons	203
Pyrites, tons	309,411
Pyrites, tons	135,893
Quartz, tons	124,033
Salt, tons	19,651
Talc, tons	620
Tripollite, tons	620

* Tons of 2000 lb.

† Ore and concentrates finally marketed estimated as 13,834 tons.

supervision. Higher costs offset advantages derived from higher prices of output and in the case of gold mining were a distinct burden.

There was an increased production of nearly all metals with the exception of lead and silver.

The total production of gold in placer and mill bullion and in smelting production in 1916 is estimated at 926,963 fine oz., valued at \$19,162,025, as compared with 918,056 fine oz. valued at \$18,977,901 in 1915. Of the total production in 1916, 26% was derived from placer and alluvial mining, 54% from bullion and refined gold, and 20% contained in matte, blister copper, residues and ores exported.

The production of silver in 1916 was 25,669,172 fine oz., as against 26,625,960 fine oz. in 1915. The production from the ores of Cobalt and adjoining silver camps was 21,885,057 oz., including 18,418,392 oz. in bullion recovered in

PLASTIC CEMENTS.

Some useful information is given by J. B. Barnitt in the February issue of the General Chemical Bulletin on plastic cements, i.e., adhesives used to secure joints and connections between like or unlike material and which are more or less perma-

nent. Physically speaking, plastic cements consist of a vehicle in which are suspended or dissolved solids of such nature that they are resistant to the gases and liquids coming in contact with them. In some cases the constituents of the cement react with each other or with the surfaces to which they are applied, thus forming a more strongly adhering mass.

The general methods of application of plastic cement are varied to suit special cases as follows: (A) Heating the composition to make it plastic until firmly fixed in place. (B) Heating the surface to be cemented. (C) Application of the cement with water or a volatile solvent, depending upon the evaporation of the solvent for drying or setting. (D) Moistening the surfaces to be cemented with water, oil, etc. (the vehicle of the cement itself). (E) Application of the cement in workable condition, setting taking place by chemical reaction, hydration, or oxidation.

Plaster of Paris. Plaster of Paris is often used alone as a paste for joints on gas and wood distillation retorts and similar places where rapidity of setting is a requisite. In order to impart strength, a fibrous material such as asbestos is often mixed with it. Shavings, straw, hair, and cloth are frequently used as binders, when a high temperature is not required, while stone, glass, and various mineral substances are used as fillers. The following cements are particularly suitable for oil vapours and hydrocarbon gases: (A) Plaster and water. (B) Wet plaster and asbestos. (C) Wet plaster and straw. (D) Wet plaster and plush trimmings. (E) Wet plaster and hair. (F) Wet plaster and broken stone.

Hydraulic cement. Cement is used either alone or with sand, asbestos etc., and is especially resistant to nitric acid. When used with rosin or sulphur it is employed as a filler rather than for any powers of setting by hydration.

Clay frequently enters into the composition of plastic cement as a filler. The finely divided condition of the material gives body to a liquid such as linseed oil which, unless stiffened, would be pervious to a gas, the clay being inert. (A) Clay and linseed oil is suitable for steam. (B) Clay, linseed oil, and fire clay for chlorine gas. (C) Clay and molasses for oil vapours.

Lime. Caustic lime and linseed oil mixtures are used as a putty. Chalk or china clay frequently replace part of the lime, but enough lime should remain to maintain the caustic property necessary to the formation of a certain amount of lime soap. Silicate and casein compositions also contain lime.

Asphalt and pitch are used interchangeably in plastic cements, pitch making the stronger binder. Tar is of less value on account of the light oils and water contained in it. Asphalt in benzol is useful as an adhesive for uniting glass for photographic and microscopical uses, also for coating wood, concrete, brick work, steel, etc., where the melted asphalt would be too thick to apply readily. Benzol is the cheapest and most satisfactory solvent. For waterproofing, melted asphalt with a small amount of paraffin added, and in particular cases boiled oil is used.

(A) Refined lake asphalt. (B) Asphalt, 4 parts; paraffin, 1 part. (C) Asphalt, 10 parts; paraffin, 2 parts; boiled oil, 1 part. Any of these may be thinned with hot benzol or toluol. (D) Pitch, 8 parts; rosin, 6 parts; wax, 1 part; plaster, $\frac{1}{4}$ to $\frac{1}{2}$ part. (E) Pitch, 8 parts; rosin, 7 parts; sulphur, 2 parts; stone powder, 1 part. Compositions (D) and (E) are used to unite slate slabs and stoneware for engineering and chemical purposes. Various rosin and pitch mixtures are also used, the proportions determined by the consistency desired. Sulphur prevents chemically

the formation of cracks, while stonepowder acts in like manner mechanically. If acid vapours or corrosive gases come in contact with the cement, limestone should not be the powder used, otherwise it is best. Wax prevents the composition from becoming brittle.

Plastic cements for caulking must be both tough and elastic and have the added property of expanding and contracting with the joint to which they are applied: (F) Pitch, 3 parts; shellac, 2 parts; pure raw rubber, 1 part. (G) Pitch, 1 part; shellac, 1 part; rubber substitute, 1 part. (F) and (G) are mixed by melting over a burner.

Rosin, shellac, and wax. A strong stone cement having little body and applied in layers. (A) Rosin, 8 parts; wax, 1 part; turpentine, 1 part.

For nitric and hydrochloric acid vapours. (B) Rosin, 1 part; sulphur, 1 part; fire-clay, 2 parts.

Sulphur gives great hardness and permanency in rosin cements. Good waterproofing cements are: (C) Rosin, 1 part; wax, 1 part; powdered stone, 2 parts. (D) Shellac, 5 parts; wax, 1 part; turpentine, 1 part; chalk, 8 to 10 parts. For a soft airtight paste for ground glass surfaces: (E) Wax, 1 part; vaseline, 1 part. A strong cement without body for metals (not copper), porcelain, and glass is (F) Powdered shellac, 1 part; ammonia water, 10 parts. Allow to stand until solution is effected.

Rubber. As a leather cement: (A) Asphalt, 1 part; rosin, 1 part; gutta-percha, 4 parts, carbon bisulphide, 20 parts. As a resistant to acid vapours: (B) Rubber, 1 part; linseed oil, 2 parts; fireclay, 3 parts. A plain rubber cement is made by dissolving crude rubber in carbon bisulphide or benzol.

Linseed oil. Linseed oil is one of the most generally useful materials for cementing purposes. For aqueous vapours: (A) China clay and linseed oil. (B) Lime and linseed oil, forming the well-known putty. (C) Red or white lead and linseed oil. The above mixtures become very strong when set and are best diluted with powdered glass, clay, or graphite. (D) Oxide of iron and linseed oil.

Casein, albumin, and glue. Cements of this nature, if properly made, become very tough and tenacious, are resistant to moderate heat and oil vapours but not to acid fumes. (A) Finely powdered casein, 12 parts; fresh slaked lime, 50 parts; fine sand, 50 parts, and enough water to make a thick mass. A strong cement for ground unions standing a moderate heat: (B) Casein in fine powder, 1 part; rubbed with silicate of soda, 3 parts. (C) White of egg made into a paste with slaked lime. This should be used immediately after being made up. A composition for soaking corks, wood packing, etc., to render impervious to oil vapours: (D) Gelatin, 2 parts; glycerin, 1 part; water, 6 parts.

Silicate and oxychloride cements for oil vapours standing highest temperature. (A) Paste of sodium silicate and asbestos. For gaskets for super-heated steam retorts, furnaces, etc.: (B) Sodium silicate and glass. (C) Sodium silicate, 50 parts; asbestos, 15 parts; slaked lime, 10 parts. Metal cement: (D) Sodium silicate, 1 part; oxides of zinc, lead, or iron, singly or mixed, 1 part. (E) Zinc oxide, 2 parts; zinc chloride, 1 part; water, to make a paste. (F) Magnesium oxide, 2 parts; magnesium chloride, 1 part; water to make a paste.

Flour and starch. (A) Flaxseed makes a very tough cement but does not withstand water. (B) Flour and molasses to a stiff paste. A permanent cement for ordinary temperatures impervious but attacked by condensing steam and nitric vapours. (C) Stiff flour paste and concentrated zinc chloride solution. As a core compound: (D) Dextrin and fine sand.

Miscellaneous. For insertion of glass tubes in brass or iron: Litharge and glycerin mixed to a stiff paste. For high temperatures:—Alumina, 1 part; sand, 4 parts; slaked lime, 1 part; borax, $\frac{1}{2}$ part; water. Core compounds: (A) Dextrin, 1 part; sand, 10 parts; water to form a thick paste. (B) Anthracite coal powdered with molasses added to thick paste. (C) Rosin, partly saponified by soda lye, 1 part; flour, 2 parts; sand, 4 parts; with water as a diluent. (D) Powdered ghte, 1 part; flour, 4 parts; sand, 6 parts; water. As a coating for glassware to protect from injury by direct flame: A mixture of fire clay and plumbeago made into a paste with water. For retorts: Fine flour and lime, 1 part; potter's earth, $\frac{1}{2}$ part; make a moist paste with white of egg well beaten with a little water. For melting pots: (A) sift brick dust and mix with equal quantity of red lead; rub together with boiled linseed oil, which has been mixed with sand to a stiffness of cement. In covering dishes apply the paste first then apply sand and heat. (B) Add freshly slaked lime to concentrated solution of borax, apply with a stiff brush and allow to dry. Upon heating a fused glaze is obtained. For large pots: Litharge, 6 parts; fresh burnt lime, 1 part; white bole, 2 parts; and mix with cold linseed oil.

MINERAL PRODUCTION OF THE UNITED KINGDOM IN 1916.

The following tables, showing the output of coal and certain other minerals in the United Kingdom at mines worked under the Coal and Metalliferous Mines Acts (the returns from quarries under the Quarries Act are not yet available) during the year 1916, with comparative figures for the preceding year, are extracted from an advance proof (subject to correction) of tables prepared for the Mines and Quarries General Report and Statistics for 1916.

Output of minerals under the Coal Mines Act.

	1915.	1916.
	Tons.	Tons.
Barium (compounds)	7477	8973
Coal	253,179,446	256,348,351
Clay and shale, other than fire-clay and oil shale	236,506	177,719
Fire-clay	1,839,746	1,712,281
Igneous rocks	79	108
Iron pyrites	9255	9496
Ironstone	6,080,218	5,648,602
Limestone	4464	2477
Oil shale	2,998,652	2,994,386
Sandstone (including "ganister") ..	141,420	160,513

* The quantity of ganister obtained was 128,938 tons in 1915, and 159,769 tons in 1916.

Output of certain minerals under the Metalliferous Mines Regulation Act.

	1915.	1916.
	Tons.	Tons.
Arsenic	2496	2534
Barium (compounds)	53,324	60,468
Bauxite	11,723	10,329
Chert, flint, etc.	3033	3202
Clay and shale	86,202	84,168
Copper ore and copper precipitate ..	746	937
Fluorspar	25,577	34,517
Gold ore	5086	1338
Gypsum	204,574	188,801
Igneous rocks	43,010	23,875
Iron ore	1,795,887	1,751,437
Iron pyrites	1280	985
Lead ore	20,698	17,084
Limestone*	283,216	235,983
Manganese ore	4640	5140
Ochre, amber, etc.	4030	4570
Rock salt	131,348	129,030
Sandstone†	57,626	32,174
Slate	48,893	46,184
Tin ore, dressed‡	6427	6161
Zinc ore	12,057	8476

* Including 271 tons of calc spar in 1915 and 67 tons in 1916.

† Including 4297 tons of ganister in 1915, and 8497 tons in 1916.

‡ In addition, 385 tons of undressed tin ore was obtained in 1915.

The above figures do not in all cases represent the total production of the minerals for the year. Large quantities of several important minerals, such as iron ore, limestone, sandstone, slate, clay, etc., are obtained from quarries under the Quarries Act, and from other open workings, the returns from which are not yet available. The totals for coal and for the ores of copper, lead, and zinc are, however, substantially complete.

Correspondence.

Berkeley, Cal., U.S.A.

24th March, 1917.

VARIABILITY OF PLANTATION PARA RUBBER.

DEAR SIR,

I write to correct a misstatement which my friends Messrs. Eaton and Grantham make in their communication (this J., 1916, 35, 1046) "Variability of Plantation Para Rubber with Different Technical Mixings." They state that the vulcanisation tests dealt with in the paper of mine to which they refer were carried out by Schidrowitz. This is not so. I was working in Schidrowitz's laboratory at the time that the vulcanisation tests were made and I pursued his methods, but the experiments, both in the East and in Europe, were conducted by myself.

Yours faithfully,

G. STAFFORD WHITBY.

To the Editor of the
JOURNAL OF THE SOCIETY OF CHEMICAL INDUSTRY.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56 Rue Ferou 8 Paris (Se.). Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Refrigerating apparatus; Absorption.—H. E. Willsie, Cranford, N.J. U.S.A. Eng. Pat. 102,080, Feb. 10, 1916. (Appl. No. 2027 of 1916.)

THE still-absorber and the condenser are con-

nected together through the evaporator, so that the refrigerating fluid passes through the evaporator as it leaves and returns to the condenser. The refrigerating fluid also passes through a chamber which serves as a moisture-trap and which seals off one set of pipes during the absorption period. The still-absorber is mounted

on a pivot and is flexibly connected with the rest of the apparatus so that the alteration in its weight operates the supply of gas to the heating arrangement. The warm water from the condenser may be used as a supply for a warm water circulating system.—W. H. C.

Liquids and gases; Apparatus for effecting the intimate contact of —. Kirkham, Hulett, and Chandler, Ltd., and S. Hersey, London. Eng. Pat. 104,261, Apr. 28, 1916. (Appl. No. 6120 of 1916.)

IN apparatus of the type described in Eng. Pat. 18,129 of 1908 (this J., 1909, 873), each of the superposed chambers is provided with several spraying devices, one central and the others arranged in a concentric circle and mounted on

separate parallel vertical driving shafts; or each chamber may be provided with two sprayers arranged symmetrically in relation to the centre of the chamber, and rotating in opposite directions. The floor of each chamber is provided with openings having upstanding flanges through which the driving shafts of the spraying devices extend, and additional openings, *q* (see Fig. I.), with upstanding flanges, *q'*, covered by serrated hoods, *r*, are provided for the upward passage of gas. When dense liquids such as heavy oils are used, the sprayer preferably comprises a collar, *s* (see Fig. II.), carrying top and bottom plates, *t*, between which intermediate annular dish-shaped plates, *u*, are fixed. The tubes, *v*, for picking up the liquid are supported by the top plate, and are provided with extended openings, *x*, for the discharge of liquid on to the plates, *t*, *u*.—W. F. F.

Boilers and the like; Production of means for preventing fur from depositing in —. O. L. K. Andersen, Struer, Denmark. Eng. Pat. 104,294, July 12, 1916. (Appl. No. 9815 of 1916.)

A SUBSTANCE for preventing boiler incrustation is produced by heating a mixture of catechu, 50–75%, sodium hydroxide 25–12.5%, and raw, ground, or grated potatoes or potato liquor, 25–12.5%, until the greater part of the catechu is dissolved. The mixture is used in the proportion of 0.5 to 1 part per 1000 of water.—W. F. F.

Drying apparatus; Air shafts for —. H. P. Dinesen, Herlev, Denmark. Eng. Pat. 104,327, Jan. 25, 1917. (Appl. No. 1248 of 1917.)

HAY, straw, or like fibrous material is stored with a number of vertical perforated tubes embedded in it, through which air is forced into or withdrawn from the material. The perforations are more numerous toward the bottom of the tubes, and sliding plates are provided on the tubes to guide the air current horizontally.—W. F. F.

Drying grain; Apparatus for —. G. Staunton, Muskegon, Mich. U.S. Pat. 1,212,275, Jan. 26, 1917. Date of appl., Aug. 4, 1913. Renewed June 12, 1916.

THE grain is placed in the upper compartment of a closed cylindrical chamber, and air is injected tangentially into a lower compartment which is provided with a heating coil of inverted conical shape and is separated from the upper chamber by a perforated partition.—W. H. C.

Drying machine. J. F. Sullenberger, Columbus, Ga. U.S. Pat. 1,216,880, Feb. 20, 1917. Date of appl., May, 6, 1916.

A VERTICAL cylindrical casing is built up of rings flanged internally and externally and separated by distance members bolted to the external flanges. A shallow pan is supported on each internal flange, the pans being provided with central and peripheral openings alternately. Each pan is heated by a coiled heating tube beneath it, and the material to be dried is moved across the surface to the opening by a rotating feeding member having depending spiral ribs. All the feeding members are mounted on a common central rotating shaft.—W. F. F.

Dryer [; Centrifugal —]. C. A. Wendell, Joliet, Ill. U.S. Pat. 1,218,024, Mar. 6, 1917. Date of appl., June 9, 1916.

A CENTRIFUGAL dryer comprises two horizontal, rotary, differentially geared members, one in the form of a delivery spout, the other acting as a projecting agent for the material. In the latter a screen is mounted at an angle to the vertical, water expelled by centrifugal action passing through the screen, and the dried material being deflected by the angle of the screen through discharge ways opened intermittently by the relative rotation of the two members.—J. E. C.

Carbon; Revivification of used finely powdered decolorising —. A. Wijnberg, Amsterdam. Eng. Pat. 104,456, July 18, 1916. (Appl. No. 10,092 of 1916.) Under Int. Conv., Feb. 25, 1916.

THE material is conveyed in alternately opposite directions through heated cylinders, the heavier particles being deposited in a collecting receptacle at the end of the course. The finer particles are drawn off along with the escaping vapours and passed to a precipitator, where separation of the vapour and solid particles takes place. Steam or water may be injected to increase the separating effect.—J. E. C.

Gaseous fluids; Apparatus for removing suspended matter from —. H. L. Doherty, New York. U.S. Pat. 1,212,193, Jan. 16, 1917. Date of appl., Apr. 4, 1912.

THE gases are passed through two or more spiral passages having their sides practically parallel and enclosed in a chamber provided with inlet and outlet ports. The free area of the spiral passages can be varied to suit variations in the quantity of gas to be passed, by raising or lowering the level of a liquid in the chamber.—W. H. C.

Fillering air; Apparatus for —. S. Cooper, Assignor to F. Offermann, Evansville, Ind. U.S. Pat. 1,214,760, Feb. 6, 1917. Date of appl., Oct. 26, 1915.

THE air is passed through a conduit across which two aprons moistened with water are stretched. The aprons are wound round two drums, one of which is perforated and serves to supply the water. The aprons are shifted simultaneously in the direction of their length by rotating the drums.—W. H. C.

Furnaces; Process of operating [producer-] gas-fired —. H. L. Doherty, New York. U.S. Pat. 1,211,520, Feb. 6, 1917. Date of appl., Mar. 31, 1909.

THE products of combustion are withdrawn from the combustion chamber through ports spaced at intervals along each side, so that approximately equal proportions are withdrawn through each port. The hot products of combustion withdrawn from one side of the furnace

are utilised to preheat the primary air, which after being saturated with water vapour is introduced into the gas producer. The products of combustion from the other side of the furnace chamber are used to preheat the secondary air.

—W. H. C.

Distillation; Method of and apparatus for fractional —. W. E. Lammus, Lynn, Mass. U.S. Pat. 1,216,331, Feb. 20, 1917. Date of appl. Apr. 6, 1916.

IN a distilling apparatus of the column type, the vapours are passed successively through a series of reflux condensing chambers. A cooling or condensing medium is circulated through the latter, the cross-sectional area and the length of path and rate of flow of the stream of cooling medium being so regulated that there is a relatively constant difference between the temperature of the medium and that of the vapours, the rate of flow of the vapours into the chambers being also regulated.—W. P. S.

Condensing and vacuum draught mechanism for furnaces. F. L. McGahan, Los Angeles, Cal. U.S. Pat. 1,217,100, Feb. 20, 1917. Date of appl. Apr. 9, 1914.

FURNACE gases enter a receiving chamber at the top of a vertical casing having in its lower part a condensing chamber provided with a rotating water-spreading device. This device consists of a vertical tubular member open at the ends and carrying helical vanes upon its exterior surface, against which water impinges to rotate the device, which is mounted on a vertical shaft. The shaft also carries a fan in the gas-receiving chamber and a centrifugal governor for regulating the water supply. The heavier elements are thus separated from the gas and treated with water, and the purified gas passes down through the spreader tube to the bottom of the casing, which is divided by a partition into a "water chamber" and a "vacuum chamber," which communicate with each other, and to the latter of which suction is applied.—W. F. F.

Filling process. A. L. Genter, Salt Lake City, Utah. U.S. Pat. 1,218,511, Mar. 6, 1917. Date of appl. Jan. 1, 1915.

SEE GER. Pat. 287,318 of 1914; this J., 1916, 243.

Solvents; Process of recovering —. T. Baker, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,218,616, Mar. 13, 1917. Date of appl. Mar. 26, 1915.

SEE ENG. Pat. 10,351 of 1914; this J., 1915, 601.

Apparatus for separating and liquefying gases. U.S. Pat. 1,215,957. See under VII.

II.A.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal carbonisation at atmospheric pressure; Effect of temperature and duration of reaction on the formation of light oils in —. M. C. Whitaker and W. R. Crowell. J. Ind. Eng. Chem., 1917, 9, 261—269.

CARBONISATION of coal at low temperatures promotes the formation of the total light and heavy oil and tar acids, whilst an increase of temperature reduces the yields of light oil and tar acids, but increases the yield of heavy oil. The oils obtained at low temperatures contain a high percentage of paraffins and unsaturated compounds and a low percentage of aromatic compounds. The maximum formation of aromatic compounds is accompanied by a decrease in the proportion of unsaturated compounds. In the case of the coal used in the investigation there was apparently a definite

relationship between the temperature and the rate of formation of benzene, toluene, and xylene. Xylene and toluene appeared to form between 400° and 900°C., and benzene between 500° and 900°C. The points of maximum formation were:—Benzene, 800°C., toluene, 700°C., and xylene, 600°C. These results agree closely with those obtained in the "cracking" of petroleum oils, and apparently the course of the reactions in the formation of benzene, toluene, and xylene is the same in both cases. It would therefore seem probable that the primary products of the decomposition of coal consist largely of paraffins of high molecular weight, which are decomposed successively into olefins, and the decomposition products (naphthenes, polycyclic compounds, etc.) which yield benzene and its homologues. The so-called "recirculation" process, in which the non-condensable distillation gases are circulated repeatedly through the retort, reduces the duration of the carbonisation reactions, and tends to increase the actual yields of heavy and light oils, as well as of the benzene, toluene, and xylene fractions. It also tends to increase the percentage yield of paraffins and to decrease the percentage yield of aromatic and unsaturated compounds in the neutral oil distilling below 170°C. Increasing the duration of the carbonisation by non-circulation gives higher percentage yields of benzene, toluene, and xylene in the light oil distilling up to 210°C., but in the zones of maximum formation of aromatic compounds (usually 700° to 900°C.) the actual yields are increased by recirculation. Both the actual and percentage yields of tar acids in the light oil show a tendency to be increased by recirculation, which supports the view that tar acids are primary products of the decomposition of coal. These results indicate the necessity for control of the temperature in the carbonisation process. For obtaining the best yields of benzene, toluene, and xylene, the temperature should not be much below 700° or much above 800°C. Good yields obtained in the gasworks at higher temperatures are attributed to the protection afforded by the cooler central core of coal which does not reach the cracking temperature, and to the dilution of the hotter gases by the cooler gases from the centre of the charge. By shortening the carbonisation process it should be possible to increase the yield of paraffin oils at low temperatures and that of aromatic compounds at higher temperatures. It is suggested that it might be possible to treat the tars obtained by carbonisation at a low temperature by the cracking processes used with petroleum oils.—C. A. M.

Coke dust or other low-grade fuel; Producer-gas, and the utilisation of —. W. Chaney, Midland Assoc. Gas Eng. and Managers, Mar. 22, 1917. Gas J., 1917, 137, 607—608.

COKE dust, passing a $\frac{1}{8}$ -in. riddle, is gasified under ammonia-recovery conditions in the Birmingham City Gasworks, and the producer gas obtained is used to heat coke-ovens, the gas from which is used wholly for town lighting, etc. The calorific value of the dust is approximately 10,000 B.T.U. per lb. and nitrogen content 1%. It is capable of yielding 45—50 lb. of ammonium sulphate per ton and 95,000 cu. ft. of gas of calorific value 111 B.T.U. per cu. ft. In practice it is found preferable to mix 40% of the dust with 60% of a producer slack, when a gas of calorific value 130 B.T.U. per cu. ft. can be obtained and the rate of gasification much increased. The thermal efficiency of retort heating with an outside producer is less than that of the normal built-in producer, but other economic advantages are claimed. The dust fuel used, which represents 3 to 4% of the coal carbonised, is usually regarded as valueless and it liberates for sale the larger

coke generally used. At the same time a fair yield of ammonium sulphate is obtained. Other advantages are the flexibility, when ovens or retorts are shut off, the uniform quality of the gas, and the absence of flue dust or clinkering troubles in the retort settings.—H. J. H.

Inflammability of carbonaceous dusts. Brown.

PATENTS.

Drying peat, and apparatus therefor. F. G. Lea, London. Eng. Pat. 103,729, Mar. 20, 1916. (Appl. No. 4117 of 1916.)

THE difficulties of drying peat which has been compressed are avoided by alternately compressing and breaking up the peat, which is at the same time heated. The disintegrated air-dried peat is fed upon an endless band which carries it through a series of hot pressing rollers; between the pressing rollers a heating apparatus is fixed below the band and a disintegrating roller above the band.—H. J. H.

Gas producer. The Hampden Cloncurry Copper Mines, Ltd., Melbourne, Australia. Eng. Pat. 100,634, Feb. 24, 1916. (Appl. No. 2790 of 1916.) Under Int. Conv., June 8, 1915.

A GAS producer is divided into an upper and a lower section by a constriction. Air is supplied through tuyères in the region of the constriction and below the grate of the lower portion. Gas is conducted from the lower half by means of an inverted U-shaped bridge and side outlet, and passing through a vaporiser generates steam which is admitted at the top and bottom of the producer.—J. E. C.

Gas; Apparatus for manufacture of —. H. Begemann, Portland, Me., Assignor to W. J. Gindele, Pawtucket, R.I. U.S. Pat. 1,217,554, Feb. 27, 1917. Date of appl., June 25, 1914.

AN apparatus for the manufacture of gas consists of an externally heated vertical retort with a cylindrical upper portion, a lateral coal inlet, and a gas outlet, the latter below the coal inlet. A close-fitting plunger in the cylindrical portion forces the coal through the retort.—J. E. C.

Gas generation; Process of —. H. E. Rider, Brooklyn, N.Y., Assignor to L. Leven, New York. U.S. Pat. 1,218,470, Mar. 6, 1917. Date of appl., Dec. 26, 1914.

THE suction of an engine is utilised to atomise oil by means of air currents through jets connected to an oil supply. The mixture of air and oil vapour is ignited and the flame smothered by passing the partly consumed gas through a restricted passage. The gas is thoroughly mixed and caused to impinge against a static body of oil. The gas, enriched by evaporation of some of the oil, passes through screens of fine mesh to break up individual currents. Air may be admitted to vary the richness of the mixture.—J. E. C.

Oil-gas producer. C. O. Nordensson, Chicago, Ill. U.S. Pat. 1,218,575, Mar. 6, 1917. Date of appl., Jan. 2, 1913.

AN oil-gas producer is provided with means for supplying a preheated mixture of air and vapour (steam) to the generator, and means controlled by the heat of the vapour-producing medium for supplying preheated oil to the generator and for mixing it with the mixture of air and vapour.—J. E. C.

Gas-washers and like apparatus. G. K. Davis, Manchester. Eng. Pat. 104,465, Aug. 23, 1916. (Appl. No. 11,964 of 1916.) (See also Eng. Pat. 17,005 of 1914; this J., 1915, 897.)

To prevent leakage in gas washers and the like, a disc is secured to the fanner shaft, causing the liquid to be thrown off at the largest diameter. The disc encircles part of a boss projecting within the body of the washer and furnished with a peripheral groove.—J. E. C.

Liquid fuel; Apparatus in which — is vaporated. D. La Cour and C. V. Schou, Copenhagen. Eng. Pat. 104,604, June 19, 1916. (Appl. No. 8640 of 1916.)

IN apparatus in which liquid fuel is to be vaporised, a piece of metal which is a good conductor of heat is heated externally to the apparatus by means of solid or liquid products of combustion of a heating cartridge, and conducts heat to the region of vaporisation.—J. E. C.

Hydrocarbon vapours; Apparatus for generating and burning —. J. I. Leary, Assignor to E. H. Doud and G. L. Hogan, Chicago, Ill. U.S. Pat. 1,216,578, Feb. 20, 1917. Date of appl., July 3, 1916.

A VAPORISING device for hydrocarbons contains passages having walls of aluminium arranged so that the liquid and vapour passing through the retort come in contact with the aluminium. The aluminium is reinforced by a wall of conducting material so that it cannot sag when heated. A fuel reservoir is provided with an outlet in its lower portion which communicates with the vaporiser. A vertical tube within the reservoir has its upper end above the fuel level and its lower end directly over the fuel outlet; an intervening screen is placed between the lower end of the tube and the outlet. Means are provided for supplying a "hydro-oxygen cleaning solution" to the vaporiser.—J. F. B.

[Petroleum] oils; Treating —. C. Ellis, Montclair, N.J. U.S. Pat. 1,216,971, Feb. 20, 1917. Date of appl., June 3, 1913.

AN oil heavier than gasoline, such as kerosene, is heated to a decomposing temperature. Liquid products are removed by condensation from the gas, which is then compressed to remove a further quantity of liquefiable products. A portion of the gas is added to the raw material entering the zone of heat decomposition.—J. E. C.

Briquettes of coal, coke, peat, ores, and the like; Process and apparatus for introducing and mixing the binding medium in making —. E. Kleinschmidt, Frankfort, Germany. Eng. Pat. 100,158, Mar. 10, 1916. Under Int. Conv., Mar. 10, 1915. (Appl. No. 3558 of 1916.)

SEE U.S. Pat. 1,207,180 of 1916; this J., 1917, 76. Other forms of apparatus for introducing the binding medium in a direction at right angles to the stream of material to be briquetted are described.

Lignite and the like; Treatment [drying] of —. T. Rigby, Dumfries, and N. Testrup, London. U.S. Pat. 1,219,155, Mar. 13, 1917. Date of appl., Jan. 11, 1913.

SEE Eng. Pat. 969 of 1912; this J., 1913, 353.

Fuel and fire-lighter; Composition —. E. H. Smirk, St. Annes-on-the-Sea. U.S. Pat. 1,219,178, Mar. 13, 1917. Date of appl., June 19, 1916.

SEE Eng. Pat. 101,813 of 1916; this J., 1916, 1210

Coking plants; Processes and means for controlling combustion in —. W. J. Mellersh-Jackson. London. From H. Koppers Co., Pittsburgh, Pa., U.S.A. Eng. Pats. 104,368 and 104,369, Feb. 26, 1916. (Appl. Nos. 2909 and 2912 of 1916.)

Vacuum apparatus [X-ray tubes]. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, U.S.A. Eng. Pat. 104,230, Mar. 7, 1916. (Appl. No. 3391 of 1916.)

THE high vacuum, in an X-ray or other electron discharge tube, is maintained by automatically and electrically disintegrating a metal within the container, in response to incipient positive ionisation of the gas evolved from parts of the apparatus during working, thus fixing the gas.—B. N.

X-ray tube. F. A. Wiggin. Lawrence, Mass. U.S. Pat. 1,218,026, Mar. 6, 1917. Date of appl., Oct. 5, 1916.

AN X-ray target comprises a face plate of tungsten alloy, a backing metal of relatively high heat conductivity, and an intermediate metal or alloy having a coefficient of expansion intermediate between that of the backing and of the tungsten alloy.—J. E. C.

Electric arc candle; Self-igniting —. J. Billiter, Vienna. U.S. Pat. 1,216,401, Feb. 20, 1917. Date of appl., Jan. 28, 1914.

ELECTRODES, placed adjacent to each other, are arranged with an intermediate layer of 20 to 60% of titanium oxide, 20 to 80% of fluorspar, 20 to 50% of titanium oxalate as binding material, and 2 to 20% of graphite.—B. N.

Revivification of used, finely powdered decolorising carbon. Eng. Pat. 104,456. See I.

III.—TAR AND TAR PRODUCTS.

Crude wood creosote from hardwood tar; Method of producing —. R. C. Judd and F. S. Acree. J. Ind. Eng. Chem., 1917, 9, 276—277.

DISTILLATION of the tar with steam is slow, consumes a large amount of steam, and gives small yields of creosote. The best method is to distil the tar by direct heat until the distillate comes over as a homogeneous liquid at a temperature well above 100° C. The temperature is then raised, and a jet of steam is introduced to stir the tar, the distillate being then separately collected, and the distillation continued until paraffin wax comes over. The heavy oil fraction should then contain not more than 1% of acid, whilst the residue of pitch can be removed without fear of coking.—C. A. M.

Beechwood creosote; Commercial —. H. K. Smith and S. F. Acree. J. Ind. Eng. Chem., 1917, 9, 275—277.

A SAMPLE of beechwood creosote containing tar and pitch distilled between 200° and 285° C., leaving 21.6% of a black solid residue. Above 300° C. the pitch decomposed and became friable when cold. The fraction distilling between 215° and 230° C. was extracted with an excess of 10% sodium hydroxide solution to remove phenolic compounds, and yielded about 40% of a neutral oil and 56% of acid oil, both of which distilled without material decomposition and without the formation of pitch. Redistillation of the acid oil yielded about 65% of a guaiacol fraction boiling between 190° and 225° C.—C. A. M.

Paradiazoinobenzene; Acyl derivatives of —. G. T. Morgan and A. W. H. Upton. Chem. Soc. Trans., 1917, 111, 187—196.

FORMYL- and acetyl-*p*-phenylenediamines on diazotising in aqueous solution in absence of strong acids, yield ill-defined diazoamines, whilst benzoyl-*p*-phenylenediamine yields benzoyl-*p*-aminobenzene-diazonium nitrite and the corresponding hydrogen carbonate. If, however, these substituted *p*-phenylenediamines are diazotised with liquid nitrous anhydride, free from nitrogen peroxide, in dry acetone, they yield formyl-, acetyl-, and benzoyl-*p*-phenylenediazoimides as pale yellow crystalline substances decomposing explosively at 125°—128° C., 127° C., and 139° C., respectively, whilst benzoyl-1,4-naphthylenediamine similarly diazotised yields benzoyl-1,4-naphthylene diazoimide, decomposing at 123° C. without explosion. Formyl- and acetyl-*p*-phenylenediazoimides are unstable at ordinary temperatures, losing nitrogen and being converted into ill-defined resinous materials, whilst benzoyl-*p*-phenylenediazoimide and benzoyl-1,4-naphthylenediazoimide are quite stable in air at the ordinary temperature. These diazoimides readily combine additively with phenols and naphthols and with bases such as the naphthylamines and *m*-phenylenediamine and its homologues, yielding azo derivatives.—T. C.

IV.—COLOURING MATTERS AND DYES.

Indigo plants; Extraction of the colouring principle of Formosan —. T. Katayama and H. Matsumoto. Kōgyō - Kwagaku Zasshi (J. Chem. Ind. Tokyo, Japan), 1917, 19, 1151—1162.

THE Formosan indigo plants (*Indigofera anil* and *Strobilanthes flaccidifolius*) belong to the indican-containing variety. The optimum temperature for the hydrolysis of the indican is 50° C., no indigo being produced at 80° C. The frothing up during the steeping does not concern the formation of indigo, being the result of rotting of vegetable matters. The colouring principle was dissolved out completely in 3 hrs. at 50° C. to give a liquid which was not contaminated with indifferent organic matters, as was the case with the ordinary

cold steeping method, and hence gave a better cake indigo. The Indigo Red content is greater if the steeping is carried out at 69°–70° C. than at 40°–50° C.—F. W. A.

Acyl derivatives of paradiazoiminobenzene. Morgan and Upton. See III.

PATENTS.

Triphenylmethane series; Dyes of the — and process of making same. A. Stock and O. Nicodenus. Assignors to Farb. vorm. Meister, Lucius, und Brüning, Höchst, Germany. U.S. Pat. 1,217,238, Feb. 27, 1916. Date of appl. June 22, 1915.

SEE Ger. Pat. 290,065 of 1914; this J., 1916, 531. Special claim is made for the dyestuff produced by heating with *p*-phenetidine the dyestuff obtained by condensing 4-chloro-2'-methyl-4'-dimethylaminobenzophenone with *N*-ethyl- α -phenylindole, and then sulphonating the product. It is a dark powder giving a reddish-blue solution in water and an orange-yellow solution in concentrated sulphuric acid, and dyes wool reddish-blue shades of great fastness to light.

Triphenylmethane dye; Blue —. M. Weiler, Elberfeld, Germany. Assignor to Synthetic Patents Co., New York. U.S. Pat. 1,218,232, Mar. 6, 1917. Date of appl., Mar. 27, 1915.

SEE Ger. Pat. 287,003 of 1914; this J., 1916, 171.

Ortho[hydr]oxymonoazo dyes. R. Kirchhoff, J. Dedichen, and W. Lange. Assignors to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 1,219,951, Mar. 20, 1917. Date of appl., Nov. 27, 1915.

SEE Eng. Pat. 16,592 of 1915; this J., 1916, 686.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Paper; Mould fungi causing deterioration of —. P. Sée. Comptes rend., 1917, 164, 230–232.

PAPER is very susceptible, in a damp atmosphere, to attack by mould fungi, many of which secrete pigment and produce specks of various colours. Examination of a stain due to mildew shows that it is made up of two portions: a central portion, generally rather dark in colour, composed of mycelium, and a peripheral zone, almost circular, paler, coloured by the secretions of the fungus, and frequently visible, owing to the diffusion of the pigment, on both sides of the paper. The germs of infection are not necessarily conveyed to the paper during storage but probably pre-exist in the material from which the paper is made. The number of species of mould fungi found in paper is strictly limited and the same forms occur in spite of the great variety of materials employed and of experimental conditions. The stains may be reproduced by infection on strips of sterilised paper without the addition of other nutritive media. Certain species are characterised by the appearance of the stain, others by the colour. Several species give a blackish stain of green, grey, brown, or maroon shade, others are characterised by specific colours: ochreous, pink, cherry-red, apple-green, brownish-yellow, pale brown, or maroon.—J. F. B.

Paper; Influence of humidity on the physical constants of —. O. Kress and P. Silverstein. J. Ind. Eng. Chem., 1917, 9, 277–282.

The sheets of paper used in the tests were suspended for 3 hours over strings in a double-walled chamber provided with a constant temperature and constant humidity apparatus, including an air pump, steam pipe, water sprays, compressor,

and fan. The humidity regulator was controlled by a silk thread which expanded or contracted with the degree of moisture in the chamber, so as to admit steam to the heating coils or compressed air into the room. The extreme ranges of humidity which could be maintained were 41 to 82 %. The series of papers included: (1) papers containing 30 % of mechanical wood and 70 % of sulphite pulp; (2) sulphite papers; (3) "kraft," 20, 30, 40 and 50 lb. papers; and (4) "kraft" 30, 40, and 60 lb. papers. It was found that an exposure of 2½ hours was sufficient to bring the papers to the required moisture content. In measuring the constants the room weight was taken on the 500 basis, sheets 24 in. by 36 in. The resistance to bursting was measured by the Mullen tester, the strength in lb. required to burst 1 sq. in. being termed the "points per lb.," whilst the "strength factor" or "points per 0.001 in." represented the results of the Mullen tester divided by the number of thousandths of an inch thickness of the paper. The tensile strength in kilos, and the % strength of the paper were determined by means of the Schopper tensile strength machine, and the resistance to folding by the Schopper folder. The average results of 5 or, in divergent cases, of 10 tests were taken. The following conclusions were drawn from the results:—(1) The value of "points per lb." increases with the decrease in relative humidity. The increase between 40 and 65 % of moisture is fairly regular, but above 70 % a large reduction in strength occurs. For example, in the case of Series I., taking the strength at 65 % humidity as the standard, there was an average variation of 8 % in strength on increasing the humidity from 41 to 65 %, whilst from 65 to 82 % the strength decreased by 21.5 %. (2) Similar results were obtained in the breaking length tests, the strength falling more rapidly above 70 to 75 % relative humidity than between 40 and 75 %. (3) The stretching capacity increases with the increase in relative humidity, the variation being more regular than in (1) and (2). In the case of the papers of Series I., the increase was 17 % on increasing the relative humidity from 41 to 65 %, and 31 % for an increase from 65 to 82 % of humidity. (4) The folding properties are more affected by the humidity than the other constants. In papers of Series I. and II., a great resistance to folding was observed between 55 and 77 % of relative humidity, but a further increase in the moisture content caused a sharp break in the folding strength. With the "kraft" papers, however, the folding strength increased with the humidity, and at 82 % of humidity they showed greater folding strength than at 77 %. It is pointed out that when papers are bought and sold on strength specifications more uniform results would be obtained if the relative humidity during the tests were also specified.—C. A. M.

[Paper testing.] *Colour; Numerical expression for — as given by the Ives tint photometer.* O. Kress and G. C. McNaughton. J. Ind. Eng. Chem., 1916, 8, 711–714; 1917, 9, 282–284.

THE Ives tint photometer consists essentially of a form of telescope into which light is admitted from two sources by means of a mirror and is focussed by a special lens into two semi-circular fields. The amount of light reflected is controlled by a shutter moved by a lever which passes over a graduated scale. The base of the eye-piece tube has a sliding carrier in which are mounted red, green, and blue colour screens, and one of colourless glass. The light is first reflected from two magnesia blocks, the shutter set at 100, and the other aperture adjusted by a thumb-screw until the two halves of the field appear of uniform intensity. The right magnesia block is then replaced by the object (*e.g.*, paper) to be tested.

Each of the colour screens is used successively, the light entering the left aperture being reduced until it is of the same intensity as that entering the right aperture reflected from the paper. The position of the lever on the scale when this equal intensity is obtained with each screen gives numerically the proportions in which red, green, and blue light are reflected by the paper. For example, an undyed sulphite paper gave readings of 77 parts of red, 71 parts of green, and 67 parts of blue. The sum of the three colours in the case of the white standard was 300, so that there was a darkening effect of 85 "parts black" in 300. Duplicate determinations can be made within one division with this instrument. In tests with papers made from specially prepared pulps tinted with various amounts of Diamond Green GN, Rhodamine B extra, Crystal Violet, and Jet Black 2 R, uniform readings were readily obtained in "parts red, green, and blue" and "parts black." A paper of brown shade dyed with Vesuvine BPX, Auramine, and Safranin T Extra Conc. was accurately matched to the eye by natural and artificial light by a paper dyed with Auramine, Safranin, and Victoria Green, and gave identical readings in the photometer. In determining the effect of calendering upon the colour, the "glare" was measured by means of Ingersoll's "glarimeter," which determines the percentage of "specularly" reflected light (*i.e.*, light reflected where the angle of incidence equals the angle of reflection) in comparison with the total reflected light. The results showed that whilst the glarimeter might be of value in determining the degree of finish of white papers, it is not suitable for coloured papers of different hues and intensity.—C. A. M.

PATENTS.

Carbonising sheep's wool; Process for —. 1. Teller, Vienna. Eng. Pat. 16,087, Nov. 15, 1915. Under Int. Conv., Jan. 22, 1915.

SEE Ger. Pat. 293,884 of 1915; this J., 1916, 1106. After treatment with the solution of zinc chloride in hydrochloric acid, the wool may be centrifuged, treated with a solution (about 15%) of sodium bisulphite, and then washed with cold water until the washings are no longer acid. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 2505 of 1876 and 8795 of 1885.)

Animal hair [wool]; Process of cleaning — and producing fertiliser. H. Y. McBride, Artesia, N. Mex. U.S. Pat. 1,218,573, Mar. 6, 1917. Date of appl., Oct. 6, 1915.

RAW wool is treated with a comminuted grease-absorbing, earthy material, *e.g.*, gypsum, which is subsequently removed, together with the absorbed grease and other extraneous matter, including "manure, humus, and the like." The wool is afterwards treated with pulverised sodium bicarbonate.

Fibrous materials; Process of fireproofing —. R. E. Prince, Madison, Wis., Assignor to the Government and People of the United States. U.S. Pat. 1,216,729, Feb. 20, 1917. Date of appl., Nov. 25, 1916. (Dedicated to the public.)

FIBROUS material is saturated with a solution of a compound of borie oxide, dried, and saturated with a soluble salt of lead.—J. F. B.

Fabric for power transmission belts; Method of treating the —. E. L. Burrell, Chicago, Ill. U.S. Pat. 1,218,052, Mar. 6, 1917. Date of appl., Feb. 13, 1915.

THE material is subjected to the action of tannic acid and the latter is fixed by means of a mordant,

e.g., tartar emetic; the treated fabric is then impregnated with a heated waterproofing compound, *e.g.*, one comprising 66% of wax tailings, 19% of paraffin, and 15% of lubricating oil, and is finally faced with an asbestine dressing containing a pigment.—J. F. B.

Fabrics; Method of impregnating —. L. Petersen-Hviid, Copenhagen, Denmark. U.S. Pat. 1,219,319, Mar. 13, 1917. Date of appl., Apr. 21, 1916.

THE fabric is treated with a mixture of rubber and sulphonated castor oil to which sulphur has been added, then dried and vulcanised.—J. F. B.

Acetylcellulose plastics; Process of making —. W. G. Lindsay, Caldwell, N.J., Assignor to The Celluloid Co., New York. U.S. Pat. 1,216,581, Feb. 20, 1917. Date of appl., Nov. 27, 1911.

ACETONE-SOLUBLE acetylcellulose is incorporated with less than half its weight of a chlorinated alkylacetanilide, *e.g.*, tetrachloro-ethylacetanilide, together with a small proportion of ethyl alcohol (1—1.5 times the weight of the acetanilide derivative) and heated. The acetanilide ingredient, when melted, is a solvent for acetylcellulose, but at the ordinary temperature, in presence of ethyl alcohol, is a non-solvent.—J. F. B.

Cellulose; Process of dissolving —. Z. Ostenberg, San Francisco, Cal., Assignor to International Cellulose Co., Reno, Nev. U.S. Pat. 1,218,954, Mar. 13, 1917. Date of appl., Jan. 31, 1916.

CELLULOSE is dissolved in a mixture of highly concentrated hydrochloric acid and a concentrated inorganic acid, *e.g.*, phosphoric acid, which does not react with the hydrochloric acid, at a temperature below 50° C., not less than 25% of hydrogen chloride being present in the mixture. —J. F. B.

Esparto or the like; Removing — from stationary digesters used in papermaking and the like. W. M. Wallace, T. Marshall, and A. Brown, Denny, Stirling, and Bertrams, Ltd., Edinburgh. Eng. Pat. 104,578, Apr. 18, 1916. (Appl. No. 5650 of 1916.)

THE digested material in the digester is broken up and removed through a discharge pipe connected with the discharge-door, by directing streams of water under pressure against the material from nozzles suitably arranged within the digester or within the discharge orifice. Alternatively, nozzles may be fitted in the feed orifice at the top of the digester and the stream of water directed against a conical member on the floor. Various means for disconnecting the discharging apparatus from the digester are described.—J. F. B.

Paper; Safety —. E. E. Schmidt, Covington, Ky. U.S. Pat. 1,217,076, Feb. 20, 1917. Date of appl., Jan. 26, 1916.

PAPER is impregnated with ox-gall and a ferrocyanide and/or magnesium sulphate.—J. F. B.

Paper stock; Means and process for refining —. P. R. Thom, Appleton, Wis. U.S. Pat. 1,217,528, Feb. 27, 1917. Date of appl., Feb. 4, 1915.

THE refiner consists of a conical casing and a conical core, rotating in the casing and slightly spaced therefrom to form a passage annular in cross-section. Unrefined stock is fed under pressure into the large end of the passage, and by reason of the relative rotation of the core and casing, the centrifugal action is caused to exert a counter-pressure on the stock effective throughout the length of the passage. The small end of the conical passage communicates with a

discharge conduit, the feeding pressure being sufficient to cause the stock to travel from the large to the small end of the passage.—J. F. B.

Paper and fabric. A. Eichler, New York. U.S. Pat. 1,218,599, Mar. 6, 1917. Date of appl., June 28, 1916.

A FLEXIBLE sheet of absorbent material or fabric is treated with a mixture containing a vegetable oil, e.g., Chinese wood oil, and polymerisation products of the coumarone and indene groups.—J. F. B.

Cork and leather substitute and process of making the same. A. L. Clapp, Braintree, Mass. U.S. Pat. 1,218,982, Mar. 13, 1917. Date of appl., July 16, 1914.

PAPER-FELT material, composed of associated wood fibres puffed or increased in diameter, with a surface-texture resembling felt, is waterproofed by the application of a rubber-like solution capable of uniting with the fibres to render them substantially waterproof, while acting as a preservative and maintaining the resiliency of the paper-felt.—J. F. B.

Waste sulphite [pulp] liquor; Process for the utilisation of—. A. D. Fest, Chicago, Ill. U.S. Pat. 1,218,638, Mar. 13, 1917. Date of appl., Oct. 30, 1915.

WASTE sulphite liquor is concentrated and treated by fermentation for the recovery of alcohol, and solid substances are precipitated from the residual solution. The precipitate is calcined and the gases produced in calcination are passed in contact with a medium capable of extracting sulphur dioxide for the production of calcium bisulphite, a suitable medium consisting of the ashes of calcination in presence of water.—J. F. B.

Impregnating woven belts and conveying-bands; Method of—. H. W. Andersen, Odense, Denmark. U.S. Pat. 1,218,350, Mar. 6, 1917. Date of appl., Oct. 29, 1914.

SEE Ger. Pat. 285,049 of 1913; this J., 1915, 1139.

Cellulose acetates; Process of treating—to alter the solubilities thereof, and products of said process. H. Dreyfus, Basle, Switzerland. U.S. Pat. 1,217,722, Feb. 27, 1917. Date of appl., Aug. 1, 1913.

SEE Addition of July 7, 1911, to Fr. Pat. 432,046 of 1911; this J., 1912, 225.

Manufacture of artificial leather, felt products, paper products, or the like. Eng. Pat. 101,536. See XV.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Achroodextrinase. Effront. See XVIII.

PATENTS.

Pectic matter from vegetable fibres; Process of removing—. B. Leech, Macclesfield. Eng. Pat. 104,202, Feb. 22, 1916. (Appl. No. 2657 of 1916.)

RAW cotton, yarn, or fabric is treated at or near the boil with aqueous hydrochloric acid of suitable strength (ascertained by experiment) to remove pectic matter as pectic acid and soluble chlorides of the bases with which the pectic acid was combined, but not sufficiently concentrated to produce a serious loss of tensile strength.—F. W. A.

Conveying of cotton, cotton waste, wool, and like textile or fibrous substances in the washing, bleaching, and like treatment thereof. T. Taylor, N. Beswick, and E. Jenkins, Hadfield. Eng. Pat. 104,214, Feb. 25, 1916. (Appl. No. 2843 of 1916.)

A CLOSED or open pipe or trough or the like is

adapted to be tilted to elevate either of its ends according to the direction in which the substance is to be conveyed, and means are provided for causing a stream of water or other liquid to flow through the pipe in either direction and for feeding to the pipe the textile or fibrous substance. The pipe may be provided with a number of discharge outlets, and with gates, which can be arranged to direct the discharge through any outlet.—F. W. A.

Cotton waste; Conveying of—in the washing, bleaching, and like treatment thereof. T. Taylor, N. Beswick, and E. Jenkins, Manchester. Eng. Pat. 104,524, Feb. 25, 1916. (Appl. No. 2842 of 1916.)

COTTON waste in process of treatment is conveyed from the washers to the bleaching or steeping boxes by feeding it into inclined closed or open pipes or troughs through which water or other liquid is caused to flow and carry the waste along with it. The pipes or troughs may be mounted on pivots so as to be capable of inclination in either direction, and may be provided with gates for discharge at any desired point. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 13,626 of 1889, 5560 of 1891, and 11,929 of 1899; this J., 1890, 856; 1900, 689.)—J. F. B.

White woollen goods; Process for producing—. A. E. Garrett, St. Albans. U.S. Pat. 1,217,744, Feb. 27, 1917. Date of appl., Aug. 30, 1916.

SEE Eng. Pat. 13,215 of 1915; this J., 1916, 687.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitrogen; Fixation of—. J. E. Bucher. Amer. Inst. Chem. Eng., Jan., 1917. J. Ind. Eng. Chem., 1917, 9, 233—253.

IN 1839 Thompson described a method of preparing cyanide by the action of atmospheric nitrogen on potash and carbon heated in a crucible in the presence of iron turnings, which he stated to be essential. In many of the later attempts (e.g., Castner's Eng. Pat. 12,218 of 1894 and Acker's U.S. Pat. 1,019,002 of 1912; this J., 1895, 572; 1912, 334) the necessity for the presence of iron was not recognised, and the industry therefore developed on the lines of electrical fixation methods. *Magnesium nitride process.* An electrolytic process was tried with the view of improving the ammonia-soda process. Magnesium chloride could be electrolysed, and the resulting magnesium burned in the nitrogen from the towers to form magnesium nitride, which could be heated with ammonium chloride from the mother liquors to produce ammonia and regenerate magnesium chloride. *Nitrogen fixation with alkali metals.*—On heating a mixture of ignited lampblack, powdered "alcoholised" iron, and metallic sodium in an iron tube through which a current of nitrogen was passed, the absorption of the gas was practically instantaneous, and only a small quantity of argon left the tube, whilst about 94% of the sodium was converted into cyanide. The reaction takes place in accordance with the equation— $2\text{Na} + 2\text{C} + 2\text{N} = 2\text{NaCN}$ —the iron acting as catalyst. This method affords a convenient means of separating nitrogen from gases of the argon group in gas analysis. *Purification of iron.*—By means of this reaction carbon, sulphur, oxygen, and phosphorus can be rapidly removed from iron, leaving it quite soft; or, if desired, the surface of the iron may be quickly purified, leaving an interior of steel. *Preparation of metallic sodium.*—The reaction is reversible, and by heating sodium cyanide with pure iron

powder in an iron tube a layer of metallic sodium is deposited in the cooler part of the tube. *Nitrogen fixation with alkali carbonates.*—When sodium carbonate is heated with carbon (powdered graphite) and powdered iron at moderate temperatures (860 to 980° C.) reaction takes place in accordance with the equation— $\text{Na}_2\text{CO}_3 + 4\text{C} + 2\text{N} = 2\text{NaCN} + 3\text{CO}$. The best results were obtained in iron tubes 10 ft. long and 2 in. in diameter. In some of the experiments the solutions extracted from the products and evaporated to dryness left residues containing over 95% of sodium cyanide. *Use of briquettes.* To obviate the disadvantages of using powders on a large scale, briquettes were made by mixing the charge of coke, soda-ash, and iron with water as near to the temperature 101–75° C. as possible, by means of a steam-jacketed kneading machine, and the hot dough-like mass was mechanically cut into briquettes 2 in. long by 2 in. broad, and 1 in. in diameter, and rapidly dried, e.g., by means of hot waste gases. The powder was prepared on an industrial scale by grinding iron scale (magnetite, hematite, etc.) to a 100-mesh powder, adding an equal weight of coke ground to the same degree of fineness, continuing the grinding for an hour, then adding the soda ash and grinding for 5 mins. Briquettes thus prepared gave products containing up to 28% of sodium cyanide, showing that iron oxides may take the place of metallic iron in the mixture. If the briquettes do not completely fill a horizontal pipe, so that an upper channel is left for the passage of the nitrogen, the yield of cyanide may fall as low as 1–4%. This may be obviated by using a vertical pipe. In one experiment the briquettes were heated in a rapid current of nitrogen in a vertical pipe, 6 ft. long by 6 in. diameter, for 1 hour 10 mins. at 1000° to 1090° C., and, on cooling, the top of the charge contained 24%, and the bottom 20%, the average being 22% of sodium cyanide. Experiments at different temperatures showed that it is possible to obtain over 30% of cyanide of 87% purity in a batch furnace below 920° within 30 mins., and that even below 820° C. considerable quantities of nitrogen are fixed within a few minutes. At mines it would be possible to fixivate the cyanide, and to mix the moist filter cake with soda ash to form new briquettes. *Continuous furnaces.*—The briquettes were introduced into the top of a vertical tube 14 ft. long, which was heated by oil burner flames. This tube opened at the base into a wider portion, beneath which was a screw conveyor to remove the hardened briquettes in which the cyanide had been formed. *Electric furnace.*—A cylindrical furnace which gave good results had a basic lining and a perforated bottom, like a Bessemer converter. It contained molten iron in which graphite fragments were deeply embedded. Sodium vapour and nitrogen were blown into the bottom of the furnace, and cyanide distilled at the top. The heat was produced by the resistance of a graphite column, which also served to keep the iron saturated with dissolved carbon. *Rate of heat penetration.*—With external heating a long time is required to heat a 6 or 8 in. column of briquettes to a uniform temperature, and with a large charge the heating would take some hours. When the briquettes were heated internally by electricity, their heat conductivity increased with the temperature and an abundant yield of cyanide was obtained from a charge of many lb. in a few minutes. *Use of air instead of nitrogen.*—Air passed through heated coke before being admitted to the tube of briquettes gave results practically identical with those obtained with nitrogen. Producer gas, flue gas, or gases from the combustion chamber of the furnace could also be used in the cyanising tubes. *Production of nitrogen.*—Pure nitrogen is readily obtained in quantity by passing air

through a vertical iron pipe 10 in. in diameter and 6 ft. long, filled with copper turnings supported on iron crosses to prevent sagging. The tube is heated in a furnace with two flues, one for the burner flame and the other for the tube, to a temperature not exceeding 450° C. When exhausted the copper is reduced with hydrogen. *Distillation of cyanide.*—Instead of fixivating the briquettes, the cyanide may be distilled from them either *in vacuo* or in a current of nitrogen. Cyanised briquettes were completely freed from cyanide by distillation in a copper tube at 1000° C. and at a pressure of about 2 mm. *Ashless carbon.*—By passing carbon monoxide over ground coke, heated in a glass tube containing finely divided iron as catalyst, an abundant deposit of carbon was obtained in accordance with the equation— $2\text{CO} \rightleftharpoons \text{C} + \text{CO}_2 + 38080$ cals. The equilibrium for this equation gives almost pure carbon monoxide at 1050° C., whilst at 500° C. the reverse action takes place. As soon as the concentration of the carbon dioxide reaches a certain point the iron becomes oxidised and loses its catalytic activity, and the course of the reaction is changed. Nickel can take the place of iron as catalyst, and does not form oxides so readily. The advantage of this process would be that a mixture of finely-divided lampblack with iron would be obtained, thus obviating the necessity of mixing and grinding, and providing internal heat in the briquettes themselves. *Oxidation of iron pipes.*—This is avoided in electrically heated furnaces, and may also be prevented in fuel-heated furnaces by regulating the proportion of carbon dioxide in accordance with the temperature. For this purpose a concentration-temperature diagram is given. For example, if the iron pipe is heated to 950° C. it would be possible to have 25% of carbon dioxide present without oxidation taking place. The carbon could be burned in accordance with the equation— $\text{C} + 2.5\text{O}_2 = 3\text{CO} + \text{CO}_2 + 181,830$ cals. without the possibility of oxidising the tube, and the remaining 203,010 cals. could be obtained by admitting sufficient air in the pre-heating zone to burn the 3CO, where the lower temperature would prevent oxidation taking place. A copper sheathing to the iron tubes might also prove a safeguard. *Destructive effect of carbon monoxide.*—In using producer gas it is essential to stop the current before the briquettes begin to cool, otherwise the cyanide formed is destroyed again, probably through the action of the carbon dioxide produced by the catalytic action of the iron in causing the formation of ashless carbon— $2\text{CO} \rightleftharpoons \text{C} + \text{CO}_2$. *Sodium ferrocyanide.*—On making the cyanide briquettes into a stiff paste with hot water, and agitating the mass, reaction takes place readily in accordance with the equation— $6\text{NaCN} + \text{Fe} + 2\text{H}_2\text{O} = \text{Na}_4\text{Fe}(\text{CN})_6 + 2\text{NaOH} + \text{H}_2$. After several hours the liquid is filtered, and deposits the ferrocyanide on cooling and concentration. In fixivating the briquettes to separate cyanide, the temperature should be kept a little above 35° C., and the operation completed as rapidly as possible to prevent the formation of ferrocyanide. At temperatures below 35° C., the mass will take up water of crystallisation to form $\text{NaCN} \cdot 2\text{H}_2\text{O}$, and will set like plaster of Paris. *Ammonia and sodium formate.*—By boiling sodium cyanide solution, to which caustic soda has been added, ammonia and sodium formate are produced— $\text{NaCN} + 2\text{H}_2\text{O} = \text{HCO}_2\text{Na} + \text{NH}_3$; the caustic soda prevents hydrolytic dissociation to form hydrocyanic acid, and “salts out” the sodium formate, which may either be returned to the cyanising process or may be heated *in vacuo* to convert it into sodium oxalate. *Urea, ammonia, and nitrogen.*—By heating the cyanide to just above its melting point in an iron pot through which is passed a current of air, sodium cyanate is formed— $\text{NaCN} + \text{O} + 2\text{N}_2 = \text{NaCNO} + 2\text{N}_2$ —the

nitrogen from which reaction is turned into the cyanising furnaces. One-half of the cyanate is heated with water, which converts it into ammonia— $\text{NaCNO} + 2\text{H}_2\text{O} = \text{NaHCO}_3 + \text{NH}_3$ —whilst the other half of the cyanate is mixed with water and the ammonia introduced. Then, by the admission of carbon dioxide from the cyanising furnace, urea is produced— $\text{NaCNO} + \text{NH}_3 + \text{H}_2\text{O} +$

The sodium chloride begins to deposit when the sea water reaches a density of 25° B. (sp. gr. 1.21) and at 27° B. (sp. gr. 1.23) about 43.5% of the total quantity separates. The salt obtained by concentrating (1) the mixture of sea water with the mother liquors and (2) the sea water alone to 32.4° B. (sp. gr. 1.29) had the following percentage composition:—

	Calcium sulphate.	Sodium chloride.	Magnesium sulphate.	Magnesium chloride.	Sodium bromide.	Potassium chloride.
1. Mixture of sea water and mother liquors ...	0.924	89.275	3.462	4.586	1.043	0.710
2. Sea water alone	0.640	96.950	0.542	0.653	1.215	—

$\text{CO}_2 = \text{NaHCO}_3 + \text{NH}_4\text{CNO}$, and $\text{NH}_4\text{CNO} = \text{CO}(\text{NH}_2)_2$. The bicarbonate is returned to the cyanising process. In this way urea is inexpensively obtained. It has been found to give results in culture experiments equal to those obtained with potassium nitrate. *Oxamide, oxalic and formic acids.*—By electrolysis the cyanide pure sodium and cyanogen are readily obtained. The cyanogen may be rapidly absorbed by 44% hydrochloric acid, which acts as a catalyst and converts it into oxamide: $(\text{CN})_2 + 2\text{H}_2\text{O} = (\text{CONH}_2)_2$. This oxamide should be of especial value as a fertiliser. By heating it with concentrated hydrochloric acid and adding water, it is converted into oxalic acid— $(\text{CONH}_2)_2 + 4\text{H}_2\text{O} + 2\text{HCl} = (\text{COOH})_2 \cdot 2\text{H}_2\text{O} + 2\text{NH}_4\text{Cl}$, and this is converted into formic acid by heating with glycerol.—C. A. M.

Potassium salts; Utilisation of the mother liquors of marine salt works as a source of— E. Manzella. *Annali Chim. Appl.*, 1917, 7, 1—27.

In the salt works at Trapani (Sicily) sea water of 3.5° B. (sp. gr. 1.025) is concentrated in the primary evaporating pans to a density of about 6° B. (sp. gr. 1.043); in the secondary pans to about 18° B. (sp. gr. 1.143); and in the tertiary pans to about 25° B. (sp. gr. 1.21). At this stage it has deposited the small amounts of iron and calcium carbonate, and about five-sixths of the calcium sulphate originally present, and is ready for feeding the salt pans (*Caselle*), in which it is concentrated to about 28.5° B. (sp. gr. 1.246), and deposits a small quantity of calcium sulphate, magnesium sulphate, magnesium chloride, and about two-thirds of its sodium chloride. In some of the works the concentration is carried to about 32° to 33° B. (sp. gr. 1.285—1.296); this, however, increases not only the yield of sodium chloride, but also the amount of other salts in the deposit. It is also a common practice to add the mother liquors to the liquid in the tertiary pans to accelerate the deposition of the salt. The following table shows the effect of concentration on the composition (in parts per 1000 of original water) of the deposits and mother liquors:—

Apart from the addition of mother liquor to the sea water in the tertiary pans, the concentration of the water to a little above 28° B. (sp. gr. 1.241) has the effect of yielding an impure sodium chloride. The bulk of the Sicilian salt is exported to Norway and America, where it is used for salting fish, and since the flavour is preferred to that of the salt from other European salt works the presence of the other salts appears to be an advantage. It is calculated that each ton of sodium chloride deposited at 32.4° B. (sp. gr. 1.29) will leave a volume of about 0.97 cub. metre of mother liquor, of which about 0.87 cub. m. would be available for the extraction of the salts. It is estimated that in the Sicilian salt works alone about 167,600 cub. m. of mother liquors would be available for the extraction of bromine and potassium salts.—C. A. M.

Carbonates; Studies of the —. Part II. Hydrolysis of sodium carbonate and bicarbonate and the ionisation constants of carbonic acid. C. A. Seyler and P. V. Lloyd. *Chem. Soc. Trans.*, 1917, 114, 138—158.

PREVIOUS attempts to determine the second ionisation constant $k_3 = \frac{[\text{H}][\text{CO}_3]}{[\text{HCO}_3]}$ of carbonic acid and the hydrolysis constant of sodium carbonate have led to results which vary greatly with the dilution of the solution. The authors show that this is due to the ionisation of sodium carbonate and bicarbonate in the solutions used. They have determined the amounts of carbonate and bicarbonate in solution in equilibrium with air containing a known amount of carbonic acid and from this they deduce the ratio between the two ionisation constants $\frac{k_2}{k_3}$ to be 7120 at 25° C.

This gives $k_3 = 4.91 \times 10^{-11}$. Values for the ionisation of sodium carbonate and bicarbonate are deduced and it is shown that the ionisation of sodium carbonate takes place in two stages, namely, $\text{Na}_2\text{CO}_3 = \text{Na} + \text{NaCO}_3$, and $\text{NaCO}_3 = \text{Na} + \text{CO}_3$, the constant for the second stage, $\frac{[\text{Na}][\text{CO}_3]}{[\text{NaCO}_3]}$, being smaller than that for the first.

Line: Effect of exposure on commercial—. J. C. Whetzel. J. Ind. Eng. Chem., 1917, 9, 287—290.

THE line used in the tests was selected by hand so as to obtain average samples, and these were exposed in boxes 6 in. \times 6 in. \times 6 in., and in barrels, for periods up to 60 days. Under actual conditions of commercial shipments, the air would have less access to the line than in the experimental tests. In the case of one sample of high-calcium lump line, the available calcium oxide had fallen from 97.2 to 83.6%, whilst the water had increased from 1.6 to 22.7%, and the carbon dioxide from 0.2 to 3.1% in 60 days in the boxes, whilst in the barrels the corresponding figures were 90.8, 1.8, and 19.4%. In the case of magnesian lines the carbon dioxide was absorbed more rapidly at the beginning than in the case of the high-calcium lines, whilst the absorption of water was less. There was little difference in the rates of absorption of carbon dioxide by ground line and hydrated line. Comparative tests indicated that carbonic acid will not be absorbed to a greater depth than 3 in. by bulk ground line in 20 days in summer weather. There is not much difference between the amounts of carbon dioxide absorbed in summer and in winter, although much more water is absorbed in summer. The absorption of carbon dioxide by hydrated line is also relatively small, a thin layer protecting the remainder from carbonation.

—C. A. M.

Nitrites: Cadmium and zinc—. P. C. Rây. Chem. Soc. Trans., 1917, 111, 159—162.

AT a dilution of 10 litres the equivalent conductivity of cadmium chloride is 53 compared with 134 for potassium chloride; a stable cadmium nitrite should therefore exist to accord with the hypothesis that a metal, the halide of which shows comparatively poor conductivity in aqueous solution, may be expected to yield a corresponding normal nitrite, since as a rule, the nitrite is also feebly ionised. Cadmium chloride on triturating with silver nitrite, with gradual addition of water, and then filtering, gives a solution which on evaporation in a vacuum over sulphuric acid yields bright, pale yellow crystals of cadmium nitrite, $\text{Cd}(\text{NO}_2)_2$. On heating gradually these decompose, giving nitric oxide as the chief gaseous product, and leave a residue of cadmium nitrate and oxide. Zinc nitrite, prepared by the interaction of zinc sulphate and barium nitrite, can only exist in dilute aqueous solution. On concentrating the solution nitric oxide is continuously evolved, leaving ultimately a residue of basic zinc nitrate.—T. C.

Boric anhydride and its hydrates. J. E. Myers. Chem. Soc. Trans., 1917, 111, 172—179.

THE velocity of hydration of boron trioxide was determined by exposure to a moist atmosphere with periodical weighings. The results indicate that there are at least two stages, the first yielding metaboric acid and on further hydration orthoboric acid. The hydration to metaboric acid is a unimolecular reaction and much faster than the further reaction. Dehydration of orthoboric acid at 100° C. proceeds as a unimolecular reaction to form metaboric acid. At a higher temperature the reaction becomes more complicated, probably on account of the formation of molecular complexes of metaboric acid.—W. H. P.

Dissociation pressure of sulphides: Method for the determination of— and its application to covellite (CuS) and pyrite (FeS_2). E. T. Allen and R. H. Lombard. Amer. J. Sci., 1917, 43, 175—195.

THE method consists in balancing the dissociation

pressure of the sulphide by a known vapour pressure of heated liquid sulphur. An evacuated glass tube, having a small bulb at each end, is used, one containing the sulphide and the other the liquid sulphur. The two bulbs can be independently heated by electrical tube furnaces placed end to end. While the sulphide is held at a chosen temperature, that of the sulphur is varied until its vapour pressure equals the dissociation pressure of the sulphide. In practice it is necessary to find two temperatures for the sulphur, thus fixing two pressures, at one of which the sulphide loses sulphur, at the other of which its dissociation product gains weight. The dissociation pressure of the sulphide lies between these limits. The method was applied to covellite (CuS) over the range 400—490° C. and pyrite (FeS_2) over the range 575—680° C. The results are expressed by the equation $\log p = -\frac{A}{T} + B \log T + C$.

For CuS , $A = -96397.514$, $B = 356.43227$ and $C = -1150.98605$. For FeS_2 , $A = 191912.61$, $B = -431.195975$, $C = -1197.56707$. The method is perhaps capable of wider application in cases where mercury pressure gauges cannot be used but where the dissociation product does not attack glass or silica. One advantage is the fact that equilibrium is approached from both sides.—H. J. H.

Sulphur dioxide and the sulphites: Iodometric determination of—. J. B. Ferguson. J. Amer. Chem. Soc., 1917, 39, 364—373.

THE principal cause of error in the analysis of sulphites and of gases containing sulphur dioxide is the oxidation which takes place in moist air or in solution containing dissolved oxygen. Rubber connections are also a source of error. For accurate determinations the gaseous mixture, preserved from all previous contact with moisture, is passed into a solution containing excess of iodine. In the case of sulphites the solid salt should be dissolved directly in an excess of iodine solution containing sufficient hydrochloric acid. When carbon dioxide and sulphur dioxide are to be determined together, absorption in potash followed by addition of the potash to an iodine solution containing an excess of hydrochloric acid is recommended, but the results are always low. If the proportion of sulphur dioxide is below 3 or 4% a correction factor may be employed, but with higher concentrations the uncertainty increases. In all cases the author recommends the performance of blank determinations to correct for the amount of iodine required to give the standard (pink) colour (Washburn, J. Amer. Chem. Soc., 1908, 30, 42) with the starch solution used.—W. H. P.

Chromium phosphate. [Volatility of platinum.] A. E. Joseph and W. N. Rae. Chem. Soc. Trans., 1917, 111, 196—202.

ON mixing cold solutions of chrome alum and disodium hydrogen phosphate, an amorphous violet precipitate of hexahydrated chromium phosphate is produced. If allowed to stand for two days in contact with the solution, the precipitate becomes crystalline without change in colour or composition. On longer standing it becomes green and again amorphous, forming the tetrahydrate. The violet crystals on boiling with water for about half an hour, form a green crystalline tetrahydrate, and on boiling with acetic anhydride a green crystalline dihydrate. Either of these at a low red heat gives a black anhydrous phosphate and at a red heat a green basic phosphate. Either the amorphous or the crystalline hexahydrate on being exposed to air slowly loses water and becomes green, retaining its amorphous or crystalline structure. The process is incomplete after two years but is pre-

sumably due to the formation of tetrahydrate. The anhydrous compound obtained by heating the amorphous green tetrahydrate is brown rather than black. The hydrated phosphates dissolve in sulphuric and hydrochloric acids, the dihydrate reacting rather slowly with hydrochloric acid. The anhydrous compound is attacked by sulphuric acid only when the acid is nearly boiling. The hydrated forms dissolve in alkalis but the anhydrous form requires strong heating with lime to bring it into an alkaline solution. Sodium carbonate solution immediately converts the hexahydrate into a green basic compound retaining alkali which is not removed by washing with water. *Volatility of platinum.*—The fact that platinum readily volatilises when heated in air is illustrated by the fact that the authors' crucible, weighing 40 grms., lost over 1 gm. during two heatings totalling 48 hours at 1100° C. in a gas furnace with a good draught (see Crookes, this J., 1912, 540).—W. H. P.

Neodymium as the cause of the red-violet colour in certain minerals. E. T. Wherry. J. Wash. Acad. Sci., 1917, 7, 143—146.

THE red-violet colour of some samples of calcite and apatite has been attributed to the presence of manganese, though both permanganates, which are too unstable to be permanent, and manganic salts, which may develop in minerals under mildly oxidising conditions, have characteristic absorption spectra which have hitherto not been observed with calcite or apatite. The presence of ferrous iron in these minerals moreover precludes the possibility of a manganic salt. Violet and red-violet specimens of apatite which are free from any underlying green colour due to ferrous iron, have recently been discovered in California, and give the characteristic absorption spectrum of neodymium.—J. N. P.

Carbon; The Penfield test for —. W. G. Mixer and F. L. Haigh. J. Amer. Chem. Soc., 1917, 39, 374—375.

THE delicacy of the Penfield test for carbon in minerals, which consists in fusing with lead chromate and observing the effect of the gases evolved on a drop of barium hydroxide solution in the same hard glass tube, has been tested by the authors. The source of carbon was a mixture of silicon carbide and alumina which could be freed from dust and other carbonaceous impurities by heating in oxygen. It was found that positive results could be obtained with a quantity of carbide containing 0.003 mgrm. of carbon.—W. H. P.

PATENTS.

Polish; Process for obtaining — from polish-rocks. F. C. Gillen. Assignor to W. A. Krasselt, Milwaukee, Wis. U.S. Pat. 1,215,517, Feb. 13, 1917. Date of appl., Apr. 19, 1915.

THE ground mineral is heated under pressure with an aqueous solution of sodium hydroxide or carbonate, whereby sodium silicate and potassium aluminate are formed. After adding borax to prevent the formation of a double sodium aluminium silicate, carbon dioxide is admitted to the solution and brings about the separation of alumina and silica and the formation of potassium and sodium carbonates, from which the potassium salt may be separated.—J. N. P.

Felspar and other polish-bearing silicious minerals; Decomposing —. W. H. Gillen, Milwaukee, Wis. U.S. Pat. 1,215,518, Feb. 13, 1917. Date of appl., Feb. 21, 1916.

THE ground mineral is mixed with borax, added to an excess of an aqueous solution of sodium hydroxide, and heated under pressure, whereby sodium and aluminium silicates are formed. Carbon dioxide is then admitted, and aluminium silicate and silica are precipitated and removed, while potassium carbonate remains in solution.—J. N. P.

Potassium compounds; Process of producing soluble —. H. P. Bassett, Catonsville, Md., Assignor to The Spar Chemical Co., Baltimore, Md. U.S. Pat. 1,217,388, Feb. 27, 1917. Date of appl., Mar. 8, 1915.

A MIXTURE of an insoluble silicate containing potassium with an alkali acid sulphate, and another salt capable of absorbing sulphur trioxide, is heated progressively to the decomposition temperature of the acid sulphate. The sulphur trioxide gas liberated by the reaction is led back and brought into contact with the mass at the commencement of the heating, when it is again absorbed and brought into action.—J. B. C. K.

Potassium-containing silicates and phosphate rock; Process of treating —. H. P. Bassett, Catonsville, Assignor to The Spar Chemical Co., Baltimore, Md. U.S. Pat. 1,217,389, Feb. 27, 1917. Date of appl., July 15, 1915.

A MIXTURE of ten parts by weight of an insoluble silicate containing potassium, and one to two parts of phosphate rock, is heated to 900° to 1200° F. (about 480°—650° C.) with 6—8 parts of sulphuric acid, an equal weight of water, and 0.5 part of carbon. At this temperature the carbon or other carbonaceous material acts as a reducing agent, and the sulphuric acid decomposes the phosphate rock, with the result that the potassium is brought into soluble form.—J. B. C. K.

Potassium salts; Process of producing —. H. P. Bassett, Catonsville, Md., Assignor to The Spar Chemical Co., Baltimore, Md. U.S. Pat. 1,217,390, Feb. 27, 1917. Date of appl., July 15, 1915.

IN order to produce soluble potassium salts, an insoluble silicate containing potassium is heated to a reacting temperature with calcium sulphate, sulphuric acid, water, and a reducing agent. As an example of the quantities used, the following are given: Green sand marl, 10 parts by weight, calcium sulphate, 1—2, sulphuric acid, 4, water, 6—8, and carbon, 0.5 parts.—J. B. C. K.

Potash and alumina; Process for extracting — from alunite. P. J. Fox, Washington, D.C. U.S. Pat. 1,217,432, Feb. 27, 1917. Date of appl., May 5, 1916. (Dedicated to the public.)

ALUNITE and a fluoride are ground together and the finely-powdered mixture is heated until the aluminium is converted into aluminium fluoride. The potash is leached out of the fused mass with water, and the residue is then treated for recovery of the aluminium by means of fluxing agents and electrolysis.—J. B. C. K.

Alkaline deposits; Process of recovering constituents of value from —. Process of recovering potassium chloride from alkaline deposits. Process of recovering borax from alkaline deposits. L. C. Jones and F. L. Grover, Syracuse, N.Y., Assignors to The Solvay Process Co., Solvay, N.Y. U.S. Pats. (A) 1,215,543, (B) 1,215,544, and (C) 1,215,545, Feb. 13, 1917. Date of appl., Aug. 30, 1916.

(A) BRINES containing sodium carbonate and potassium salts and borates are treated with carbon dioxide, and the sodium bicarbonate

precipitated is removed. Sodium carbonate, which is recovered later, is then added in sufficient quantity to prevent the precipitation of potassium salts. The solution is concentrated at a high temperature, when sodium carbonate, chloride, and sulphate are precipitated and boric acid and its less soluble salts are converted into the more soluble sodium metaborate. On cooling, potassium chloride is precipitated. The operation may be modified by treating a portion only of the brine with carbon dioxide, removing the bicarbonate, and adding the remaining treated solution to the original untreated portion, then concentrating at a high temperature to precipitate sodium carbonate, chloride, and sulphate, and finally cooling to precipitate potassium chloride. (i) The brine is concentrated at a high temperature, when boric acid salts are converted into more soluble sodium metaborate and the less soluble sodium salts are precipitated. The concentration is continued until the solution is saturated with potassium chloride at the temperature employed. The potassium chloride is then precipitated by cooling, and removed. The mother liquor containing sodium metaborate is returned to each succeeding batch of brine until the solution is saturated with this salt, when it is precipitated as borax, and the remaining solution is added to the next portion of brine to be treated. (c) Alkaline brines containing sodium carbonate are heated to convert boric acid and its less soluble salts into the more soluble sodium metaborate. The solution is concentrated at a high temperature to precipitate sodium carbonate, sulphate, and chloride, and then cooled to precipitate potassium chloride. The solution is then treated with carbon dioxide to convert the sodium metaborate into borax, which is precipitated.—J. N. P.

Potassium and magnesium chlorides; Process of recovering—from natural deposits. L. C. Jones, F. L. Grover, and J. L. Silsbee, Syracuse, N.Y., Assignors to The Solvay Process Co., Solvay, N.Y. U.S. Pat. 1,215,546, Feb. 13, 1917. Date of appl., Oct. 23, 1916.

THE brine is evaporated at a relatively low temperature until nearly saturated with respect to potassium chloride. The sodium chloride, which is precipitated during the concentration, is removed, and the evaporation of the liquor is continued at a high temperature, with further separation of sodium chloride, until, at the temperature employed, it is saturated with potassium chloride but not with magnesium chloride. The liquor is cooled to precipitate potassium chloride, which is removed, and is then evaporated at a high temperature, with further precipitation of sodium chloride, until again saturated with potassium chloride, and cooled to give a second crop of this salt. To recover the magnesium chloride which remains in solution, the final mother liquor is evaporated at a high temperature, and the carnallite which precipitates is removed, until a fused product remains containing about 48% $MgCl_2$ and 52% water. Solid potassium chloride is removed from the carnallite by dissolving away the magnesium chloride in a liquor saturated with potassium chloride but unsaturated with magnesium chloride.—J. N. P.

(A) (B) *Alkaline deposits; Process of recovering constituents of value from natural —.* (C) *Process of separating mixed potassium chloride and borax.* J. D. Pennock, L. C. Jones, and F. L. Grover, Syracuse, N.Y., Assignors to The Solvay Process Co., Solvay, N.Y. U.S. Pats. (A) 1,215,574, (B) 1,215,575, and (C) 1,215,576, Feb. 13, 1917. Dates of appl., Dec. 16, 1915, Jan. 14, 1916, and Sept. 12, 1916.

(A) The sodium carbonate present in the solution

of the material is converted into bicarbonate and removed. The solution is then evaporated, when sodium chloride and sulphate are deposited and potassium salts retained. Calcium chloride and milk of lime are added to convert sulphate, borate, and carbonate compounds into insoluble calcium salts. The product is filtered and the solution is subjected to alternate hot and cold crystallisation to recover separately the remaining sodium and potassium chlorides. (B) The solution is treated with carbon dioxide to convert sodium carbonate into bicarbonate, which is precipitated and removed. Potassium sulphate and sodium chloride, which are obtained at a later stage of a previous operation, are added to the solution in such quantity that upon concentration by evaporation at a high temperature, all the sulphate will be precipitated and the solution will be left with double the potassium content of the original lake water. During this evaporation, sodium sulphate and chloride are first precipitated and removed, then potassium sulphate and sodium chloride are precipitated. The potassium chloride remains in solution and is precipitated by cooling. (C) A solution containing approximately 23.6% potassium chloride, 8.6% borax, and 67.8% water is concentrated at a high temperature until saturated with potassium chloride while remaining unsaturated with borax. The mixed salts are added to the solution until it is saturated with borax, and while still hot, the undissolved potassium chloride is removed. Water, equivalent in amount to that removed by the evaporation, is then added to the solution, which is cooled and the borax removed by crystallisation.—J. N. P.

Salts; Process of recovering—from mixtures in solution. E. N. Trump, Syracuse, N.Y., Assignor to Solvay Process Co., Solvay, N.Y. U.S. Pat. 1,216,187, Feb. 13, 1917. Date of appl., Mar. 24, 1916.

THE solution is subjected to fractional crystallisation in a series of evaporating vessels which are maintained at progressively increasing temperatures. During the concentration, the solution circulates from the vessel at the highest temperature to the one at the lowest, and the salt precipitated in each vessel is transferred to the adjacent one at a higher temperature, whereby the more soluble salt is dissolved. The final products of the separation are removed from the vessels at each end of the series.—J. N. P.

Aluminium chloride; Manufacture of —. A. McD. McAfee, Port Arthur, Assignor to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,217,471, Feb. 27, 1917. Date of appl., Sept. 29, 1916.

FINELY-DIVIDED hydrated alumina, or undried bauxite, is mixed with finely-divided coking coal, with or without a temporary binder, the mixture is coked, and is then submitted to the action of chlorine gas, or of a gas containing chlorine.

—J. B. C. K.

Aluminium chloride; Art of producing —. M. Barnett and L. Burgess, New York, Assignors to Alchior Chemical Co. U.S. Pat. 1,218,588, Mar. 6, 1917. Date of appl., Aug. 14, 1916.

ALUMINIUM carbide is treated with hydrochloric acid gas in the presence of heat, and the aluminium chloride produced by the reaction is volatilised and condensed. The other gases evolved during the reaction are employed for heating the retort. The apparatus used consists of a furnace, a retort within the furnace, a condenser, a charging-hopper, and gas-burners for heating the furnace with the evolved gases.—J. B. C. K.

Liquefying and separating gases [air]; Apparatus for —. R. Mewes, Berlin. U.S. Pat. 1,215,957, Feb. 13, 1917. Date of appl., Oct. 7, 1915.

Air at low pressure is cooled by a counter-current device and fed to a coil within a separating chamber and opening into it. The air passes from the separating chamber to an expansion chamber and thence to a second coil in the separating chamber. Air rich in oxygen is forced at high pressure by a cooled compressor through a third coil in the separating chamber, in counter current to the expanded air, to a throttle valve, from which it issues into the separating chamber. Air rich in nitrogen is similarly compressed and passed through a fourth coil in the separating chamber to a throttle valve, from which it also issues into the separating chamber.—W. F. F.

Sulphuric acid; Apparatus for the continuous concentration of —. S. Dreyfus, Denton, Lancs. U.S. Pat. 1,217,577, Feb. 27, 1917. Date of appl., Jan. 10, 1917.

SEE Eng. Pat. 101,642 of 1916; this J., 1916, 1155.

Sulphuric acid; Process of producing —. P. Farup, Gløshaugen, Assignor to Det Norske Aktieselskab for Elektrokemisk Industri, Christiania, Norway. U.S. Pat. 1,219,277, Mar. 13, 1917. Date of appl., Feb. 25, 1913.

SEE Fr. Pat. 454,893 of 1913; this J., 1913, 867.

Sodium thiosulphate; Process for the manufacture of —. T. W. S. Hutchins, L. Hargreaves, and A. C. Dunningham, Middlewich. U.S. Pat. 1,219,819, Mar. 20, 1917. Date of appl. Aug. 18, 1916.

SEE Eng. Pat. 12,599 of 1915; this J., 1916, 1059.

Process of producing cement and recovering potassium compounds. U.S. Pat. 1,219,315. See IX.

VIII.—GLASS; CERAMICS.

PATENTS.

Plate glass; Manufacture of —. R. S. Pease. Assignor to Pittsburgh Plate Glass Co., Pittsburgh, Pa. U.S. Pat. 1,217,340, Feb. 27, 1917. Date of appl., June 5, 1915.

A SHALLOW pot is partially filled by dipping it into molten unrefined glass contained in a tank. The pot is then allowed to float on the surface of the molten glass and is moved forward and exposed to a refining heat. When the glass in the pot is sufficiently refined, the pot is allowed to cool slightly and is then removed from the tank and the glass poured into another vessel.

—A. B. S.

Pots for the manufacture of plate glass, and method of making same. C. H. Kerr, Tarentum, Pa., Assignor to Pittsburgh Plate Glass Co., Pittsburgh, Pa. U.S. Pat. 1,217,956, Mar. 6, 1917. Date of appl., May 8, 1914. Renewed Nov. 18, 1916.

POTS for melting plate glass are made of ordinary glass-house pot clay mixed with finely divided silica or sand, so that the mixture contains 8 to 30% of the silica. The sand is of such fineness that the major portion consists of grains less than 0.05 in. diameter.—A. B. S.

Glassware; Process of producing decorative colour effects on —. H. Northwood, Wheeling, W. Va. U.S. Pat. 1,217,490, Feb. 27, 1917. Date of appl., Sep. 28, 1916.

The ware is stained with copper sulphate solution (with or without a binder such as ferruginous clay), fired at 900° F. (480° C.), cooled, and the binder removed. It is then coated with a solution of a silver salt (with or without a binder) and re-fired at the same temperature.—A. B. S.

Carborundum articles. G. A. Balz, Rahway, N.J., U.S.A. Eng. Pat. 103,818, Dec. 19, 1916. (Appl. No. 18,199 of 1916.) Under Int. Conv., Jan. 28, 1916.

POWDERED or granulated carborundum (firesand) is mixed with about 2% of slaked lime or other alkaline-earth hydroxide and sufficient water to make the mass plastic. Articles are made by pressing or moulding and then burning at 1400° C. or somewhat higher so as to flux or frit the material. Bricks, etc., made in this way are extremely refractory and may be used under conditions for which neither aluminous nor silicious materials are satisfactory.—A. B. S.

Kiln construction. C. H. Zwernmann, Kalamazoo, Mich. U.S. Pat. 1,216,590, Feb. 20, 1917. Date of appl., Dec. 4, 1916.

THE goods to be burned are supported in the centre of the kiln, and are separated from the combustion chambers at each side by partitions. A series of lateral and upright tubular flues is connected to each combustion chamber. The inner and outer walls of the kiln are insulated from each other.—A. B. S.

Glass; Production of articles of — and apparatus therefor. J. Connolly, Manchester, and J. A. Temple, Richmond. Eng. Pat. 104,555, Mar. 15, 1916. (Appl. No. 3818 of 1916.)

Glass; Method of and apparatus for conveying molten —. Art of feeding molten glass. W. J. Mellersh-Jackson, London. From Hartford-Fairmont Co., Canajoharie, N.Y., U.S.A. Eng. Pats. 104,605 and 104,606, June 19, 1916. (Appl. Nos. 8648 and 8653 of 1916.)

Cutting, cleaning, or polishing material [abrasive]; Manufacture of a —. Naaml. Vennootschap West Borneo Cultuur Maatschappij, The Hague. Eng. Pat. 100,140, Mar. 4, 1916. Under Int. Conv., Mar. 4, 1915. (Appl. No. 3290 of 1916.)

SEE Fr. Pat. 481,099 of 1916; this J., 1917, 139.

Carborundum article and process of making it. G. A. Balz, Rahway, N.J. U.S. Pat. 1,217,683, Feb. 27, 1917. Date of appl., Jan. 28, 1916.

SEE Eng. Pat. 103,818 of 1916; preceding.

IX.—BUILDING MATERIALS.

Wood; Chemistry of the decay of —. R. E. Rose and M. W. Lisse. J. Ind. Eng. Chem., 1917, 9, 284—287.

SAMPLES of sound, partially decayed, and completely rotten wood from Douglas firs were analysed with the following average percentage results:—

	Soluble in cold water.	Soluble in hot water.	Alkali-soluble.	Cellulose.	Acid hydrolysis.	Pentosans.	Methyl-pentosans.	Methoxy group.	Moisture (40-mesh).	Moisture (sawdust).	Ether extract.	Ash.
Sound heart wood	4.03	2.23	10.61	58.9	0.71	7.16	2.64	3.94	9.81	10.22	2.71	0.15
Partially decayed	1.79	4.19	38.10	41.66	0.28	6.79	3.56	5.16	10.63	9.09	2.05	0.15
Completely rotten	1.16	7.77	65.31	8.47	0.17	2.96	6.06	7.80	9.09	8.97	2.72	0.65

The cellulose was determined by Cross and Bevan's method on the sawdust, and the other constituents on powder passing through a 40-mesh sieve. Pentosans and methylpentosans were determined by Tollens' method, and the methoxy group by Zeisel's method. For the acid hydrolysis 2 grms. was boiled for 3 hours with 2.5% sulphuric acid, and the volatile acids distilled, titrated, and calculated as acetic acid. The alkali-soluble substances were determined by heating 2 grms. on the water-bath with 100 c.c. of 1% sodium hydroxide solution, and deducting from the loss in weight the percentage removed by the hot and cold water and ether extractions and the acid hydrolysis. The results indicate that the alkali-soluble material is formed at the expense of the cellulose, the determination of which might serve to detect incipient decay. The lignin is more resistant to decay than the cellulose, and does not appear to decay uniformly, the portion first attacked being that which yields acetic acid and furfural on hydrolysis. The more resistant portion appears to be that which yields methylfurfural on treatment with strong hydrochloric acid, and methyl iodide when heated with strong hydriodic acid.—C. A. M.

Polash [potassium] salts; Volatilisation of— from cement materials. E. Anderson and R. J. Nestell. J. Ind. Eng. Chem., 1917, 9, 253—261.

EXPERIMENTS described in detail show that the potassium oxide in any cement material can be completely volatilised, the velocity and extent of the volatilisation depending upon the temperature, length of exposure, and the volume of gas present, whilst in the kiln the size of the clinkers has also an influence. The potassium oxide is expelled more readily from some materials than from others. Volatilisation begins at about 1100° C. and at 1200° to 1300° C. most of the potassium oxide can be expelled from any cement material. The velocity of volatilisation increases rapidly with the temperature, and at 1100° C. nearly the whole of the potassium oxide can be expelled in a very short time. The presence of chlorides, and especially of calcium chloride, increases the speed of volatilisation, whilst sulphates have a retarding influence. It is therefore an advantage to add chlorides to the material. The presence of sulphur dioxide in the furnace gases decreases the rate of volatilisation, owing to the formation of sulphates. Sodium oxide is volatilised nearly as readily as potassium oxide. The most suitable means of obtaining the maximum volatilisation of potassium oxide is to burn the material at a high temperature in kilns so constructed that the material is kept as long as possible in the hot zone and in contact with the hot stream of gas.—C. A. M.

PATENTS.

Roads; Method of and material for surfacing— R. E. Phillips, London. From J. N. Honeyman, Middlesbrough, and P. H. Watson, Hartlepool. Eng. Pat. 101,472, Sep. 27, 1916. (Appl. No. 13,720 of 1916.)

ROAD surfaces are rendered dustless by damping them and then covering them with a mixture of 1 part of finely ground salt-crust from brine pans and three parts of pulverised stone or slag. The wet mixture is immediately rolled in.—A. B. S.

Concrete or artificial stone; Composition of— for blocks and the like. E. O. C. Howells, Coventry. Eng. Pat. 101,595, Mar. 23, 1916. (Appl. No. 7771 of 1916.)

BLOCKS for kerbs, channels, mullions, etc., are

made of concrete composed of 4 parts of granite and 1 part of Portland cement to which is added 10% of crushed Bessemer steel slag. It is claimed that such blocks are 60% stronger than those made of ordinary concrete.—A. B. S.

Cement; Process of producing—and recovering potassium compounds. F. W. Huber and F. F. Reath, Riverside, Cal. U.S. Pat. 1,219,315, Mar. 13, 1917. Date of appl. Sep. 26, 1916.

THE flue dust from cement kilns is mixed with an alkaline-earth halide (such as calcium fluoride) and then heated to a cement-forming temperature under conditions capable of liberating and volatilising the alkalis. The volatilised alkali is collected in the form of a flue dust which is mixed with calcium fluoride and digested with water to extract the potash.—A. B. S.

Timber and other material; Impregnating—with a preservative. O. P. M. Goss, Seattle, Wash. U.S. Pat. 1,219,388, Mar. 13, 1917. Date of appl. Oct. 11, 1915.

THE timber is heated with a bituminous preservative in a closed container at 230° F. (110° C.) first under atmospheric pressure and then in a vacuum of 15 to 28 in. for at least 30 mins. The vacuum is then broken and sufficient pressure applied to force from 5 to 20 lb. of the preservative into each 1 cu. ft. of timber. The fluid may then be heated for a further period of 1 to 6 hrs. under atmospheric pressure, after which it is allowed to run out of the container, and a vacuum of 15 to 28 in. is created in the latter.—A. B. S.

Process of fireproofing fibrous materials. U.S. Pat. 1,216,729. See under X.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steel forgings; Heat treatment of— H. H. Ashdown, Inst. Mech. Eng., Mar. 16, 1917. Engineering, 1917, 103, 266—270.

FURNACES of the approximate dimensions, 8 ft. by 10 ft. by 100 ft., with a total capacity of 150 tons of miscellaneous forgings, are now extensively employed in large steel works. The temperatures employed, which vary from 650° C. (1200° F.) to 927° C. (1700° F.), are generally controlled pyrometrically, though through non-uniformity the values recorded are necessarily only local temperatures, according to the position of the pyrometer. Unless the former temperature is exceeded, comparatively little change is effected in the structural condition of the metal. Forgings, or any part of them, which have been raised to a high temperature and received little or no subsequent working, retain on cooling a very coarse structure with consequent mechanical weakness. The best structural conditions are obtained by allowing the heated forging first to fall below its recalescence temperature and then reheating somewhat above this point and preferably cooling in air. The maximum hardening of steel is obtained by quenching at a temperature just above its recalescence point, by ensuring that the temperature is uniform throughout the metal, and by cooling as rapidly as possible until the critical range has been passed. In both quenching and annealing, the best results have been obtained by not exceeding 813° C. (1500° F.). Above this point a coarse structure develops and increases the more rapidly the higher the temperature. Excessive heating before quenching also renders the cooling medium unnecessarily hot and thus causes a comparatively

slow cooling of the forging through its critical stage, allowing partial precipitation of the ferrite. Water serves as a very satisfactory quenching medium, and in the case of large masses of steel, such as gun forgings, has the advantage of obviating the expense and risk attending the use of large quantities of oil. Steels may be annealed for the purpose of subsequent machining by burying in sand, which for small forgings should first be heated, so that the metal is completely covered before the temperature has fallen below the critical point. Failures in the annealing of forgings of irregular shape have been caused by the large difference in time taken by the different parts of the forging to acquire a given temperature during the heating, thus causing deterioration of the areas of smaller section through prolonged exposure to high temperatures. This defect has been obviated by subjecting the forging for a long interval to a temperature of about 704° C. (1300° F.), when little structural change is undergone, and then gradually raising to the predetermined temperature.—J. N. P.

[Steel] forgings; Heat treatment of large —. W. Beardmore. Inst. Mech. Eng., Mar. 16. 1917. Engineering, 1917, 103. 270—271.

The difficulties of the heat treatment of forgings increase with the size, as the mechanical properties, which depend on the crystalline growth or size of grain, are largely influenced by the time the material is maintained at any chosen temperature and by the rate of cooling. A limit is thus ultimately reached in the size of the forging beyond which a plain carbon steel cannot be used with safety and an alloy steel becomes necessary. The slowness of cooling of the inner layers of heavy masses of steel results in the formation of large crystal grains in the centre, and necessitates oil quenching to accelerate the cooling and diminish the size of the grain. In these cases a subsequent reheating is generally necessary to remove the hardness introduced by the quenching. In the case of very large forgings, however, the effect of oil quenching is limited to the outer layers, an area in the centre remaining unaffected. An oil-treated shaft of 18 inches diameter, and of the following percentage composition: C, 0.18, Mn, 0.65, Si, 0.10, S, 0.048, P, 0.037, was maintained for two hours at 820° C. (1505° F.), and cooled in oil, giving a product with the following properties:—

	Elastic limit.	Ultimate stress.	Elongation on 2 in.	Reduction of area.
	Tons per sq. in.	Tons per sq. in.	Per cent.	Per cent.
Outside layer	17.5	33.1	27.0	53.1
Centre	15.0	29.0	31.0	46.0

The intimate relation which exists between the nature of the grain and the amount of work applied during forging makes it desirable that in every part the cross-section should be reduced to at least one-third of the original section of the ingot. For materials of a tensile strength exceeding 40 tons, it is generally safer to use an alloy steel, while for a tensile strength below this figure, an oil-treated low-carbon steel is satisfactory. In the furnace treatment of forgings of non-uniform thickness, the premature heating of the areas of smaller section, resulting in the progressive growth of the crystalline grain, can be avoided by enclosing the narrower parts in asbestos sheets. When, by machining, the outside surface has been removed from large forgings, which have been quenched during the heat treatment, distortion is apt to

occur, probably owing to internal stresses acquired during the operation of quenching. It is advisable on this account first to machine roughly the forging after treatment and then to re-anneal before the final machining.—J. N. P.

Steel: Determination of carbon in — by micro-graphical examination. A. Portevin. Rev. Mét., 1916, 13, 426—428.

THE estimation of carbon in steels by measuring under the microscope the relative proportions of ferrite and pearlite, may be disturbed by the inequality of the distribution of carbon throughout the metal. This heterogeneity, which is not indicated by chemical analysis, may be detected by observing large surfaces with a low magnification. Errors may also arise through the ferrite and pearlite being deposited in laminated schist-like form. In this case, duplicate sections, one parallel, and the other perpendicular, to the direction of the alinement of the layers, should be examined. Variations in the fineness of the texture lead to the necessity of varying the magnification with each specimen, so as to bring the mean dimensions of the areas of ferrite and pearlite to the same scale. Samples of metal for examination must first be subjected to the same conditions of annealing, as the structure of the pearlite and its association with ferrite and cementite are largely modified by the heat treatment received. The presence of manganese and chromium, which affect the relative proportions of ferrite and pearlite, gives an illusory high value in the micrographical estimation of carbon. —J. N. P.

Development of United Kingdom Mineral resources. New branch of the Ministry of Munitions.

A NEW Branch of the Ministry of Munitions has been established under Sir Lionel Phillips, Bart., as Controller, to deal with the examination and development of such mineral properties (other than coal or iron ore) in the United Kingdom as are considered likely to be of special value for the purposes of the war. The Minister of Munitions has appointed the following gentlemen to act as an advisory Committee on the development of mineral resources:—Sir Lionel Phillips, Bart. (Chairman), Mr. F. J. Allan, Mr. C. W. Fielding, Mr. R. J. Frecheville, Professor F. W. Harbord, F.I.C., Assoc. R.S.M., Mr. F. Merricks, Sir Harry Ross Skinner, Dr. A. Strahan, LL.D., F.R.S. (representing the Geological Survey), and Mr. Edgar Taylor, together with a representative to be nominated by the Board of Trade.

[Silver:] Sodium sulphide precipitation [of —] at Niissing. R. B. Watson. Bull. Canadian Inst. Min. Eng., Nov., 1916. Eng. and Min. J., 1917, 103, 378—379.

OWING to the increased cost of aluminium, sodium sulphide has been substituted for aluminium powder (this J., 1913, 660) for precipitating cyanide solutions. The solution is agitated with sodium sulphide solution, the required amount of the latter being ascertained by constant testing of the spent solution leaving the filter-press. The slight excess of sulphide required for complete precipitation is destroyed by aeration, after which the regenerated cyanide liquor is returned to the treatment tank. The silver sulphide precipitate is made into a pulp with 4 parts of 8% caustic soda (0.03 lb. NaOH per oz. Ag). The pulp circulates through a small tube-mill containing 300 lb. of aluminium ingots. After 10—12 hours, desulphurisation is complete: $2Al + 3NaOH + 3Ag_2S = Na_2Al_2O_4 + 6Ag + 3NaSH + H_2O$. The metallic precipitate is filter-pressed, washed for

2 hours, and melted down to bullion (996 fine). The slag is saved and put through a small blast-furnace. The process cannot be used for precipitating gold from cyanide solutions.—W. R. S.

Flotation [of oxide ores]; Notes on —, J. M. Callow. Amer. Inst. Min. Eng., Feb., 1917. Met. and Chem. Eng., 1917, 16, 250-252.

THE tailing of the Magma (Ariz.) mill, carrying considerable quantities of oxides, is sulphidised by hydrogen sulphide, and subsequently concentrated by flotation (this J., 1916, 929). The gas is forced by means of a centrifugal pump through the pulp in a closed cell. It was found that hydrogen sulphide in proper quantity promotes the flotation of natural sulphides refractory to other concentration processes, and uniform recovery of both the natural sulphides and the oxides coated with a film of sulphide is obtained. The hydrogen sulphide is made by heating sulphur with $2\frac{1}{2}$ parts of California crude oil to 300°C . in a retort. The solution is blown at the head of the first flotation cell, as free gas in the pulp is harmful. The sulphur consumption is $\frac{1}{2}$ — $1\frac{1}{2}$ lb. per ton of tailing, and 3 lb. per ton of carbonate ores containing 3—4% of copper.—W. R. S.

Tungsten-molybdenum alloys. F. A. Fahrenwald. Amer. Inst. Min. Eng., Feb., 1917. Met. and Chem. Eng., 1917, 16, 249.

THE alloys were prepared by compressing mixtures of reduced tungsten and molybdenum, in the form of powder, into briquettes and heating by an electric current in an atmosphere of hydrogen. The solidus curve was found by optical pyrometer measurements. The equilibrium diagram showed no critical points, and the curve for hardness was typical of an uninterrupted series of solid solutions. The two metals were found to be completely isomorphous. All the alloys of the series are malleable and ductile.—W. R. S.

Resiliency tests [on metals]. G. Charpy and A. Cornu-Thenard. Comptes rend., 1917, 164, 473—477.

THE degree of bending of metals by impact reveals differences in the physical condition which are not shown by other mechanical tests. Measurements were repeated about five times with bars of steel and copper prepared as far as possible under the same conditions and the extreme and mean variations are tabulated. The resistance to impact of a number of carefully notched test-pieces of metal gave results of a regularity comparable with those obtained in measurements on yield point, elongation, and hardness. Measurements by the falling weight method of the resiliency of similar straight bars of steel were found to give results which were independent of the height of fall, value of weight, and dimensions of the apparatus. With notched test-pieces the resiliency falls rapidly in proportion to the depth of the groove, but with metals of similar size and shape is a definite physical constant.—J. N. P.

PATENTS.

Refining volatile metals [electrically]. S. Hultdt, Stockholm, Sweden. Eng. Pat. 101,211, July 27, 1916. (Appl. No. 10,613 of 1916.) Under Int. Conv., Aug. 14, 1915.

THE zinc or other volatile metal to be refined is introduced into the chamber of an electric arc radiating furnace through an opening in the furnace wall, until a molten metallic bath is formed, and the opening is then closed. Fresh material is introduced at the bottom of the bath through a liquid trap formed by the molten metal, and the zinc distilled from the surface of the metal is continuously exhausted for condensation through an outlet in the top of the chamber.—B. N.

Ores; Reduction of — [electrically]. G. E. Heyl, London. Eng. Pat. 104,064, Apr. 7 and 13, 1916. (Appl. Nos. 5132 and 5129 of 1916.)

THE ore is crushed with the necessary fluxes and reducing agents, and the mixture, in the form of a thin rod or ribbon, is fed by a suitable apparatus into an enclosed chamber to a region, immediately below an electric arc or series of arcs, in which a reducing temperature is maintained.—B. N.

Rust-proofing metal; Process for —. W. H. Allen, Assignor to Parker Rust-Proof Co. of America, Detroit, Mich. U.S. Pat. 1,215,463, Feb. 13, 1917. Date of appl., Nov. 6, 1915.

ARTICLES of iron and steel are rendered rust-proof by immersing them in a boiling solution containing 0.8% of acid ferric phosphate.—B. N.

Ore; [Electrically] sintering and smelting —. A. S. Dwight, New York. U.S. Pat. 1,215,635, Feb. 13, 1917. Date of appl., Mar. 31, 1910. Renewed June 15, 1916.

A LAYER of ore is sintered by the combustion of contained materials into a continuous sinter cake, and the latter is moved continuously away from the region where it is formed. The intermediate portion of the cake is subjected to an electric current to raise its temperature, and a current is also passed from the forward end of the cake to a conducting electrode which is relatively stationary.—B. N.

Ores; Process for treating —. Apparatus for roasting and sintering ores. A. S. Dwight, Assignor to Dwight and Lloyd Sintering Co., Inc., New York. U.S. Pats. (A) 1,215,636 and (B) 1,215,637, Feb. 13, 1917. Dates of appl., (A) July 7, 1913, and (B) Oct. 21, 1914.

(A) SULPHIDE ore is roasted in shallow layers to obtain a uniformly porous sinter-cake, and air is passed through the material. Whilst the ore and gases are still hot, the air is again passed through the material to enrich the gas in sulphur dioxide. (B) Two grate surfaces are arranged for supporting and roasting a relatively thin layer of ore, and a box is arranged under each grate surface for collecting the products of combustion. The air-box under the first grate is divided into two chambers, one of which is connected by a gas duct to the suction side of a fan, and the latter drives

the gas into a hood covering the ore on the second grate, so that the gas again passes through the ignited ore. The products of combustion, from the second chamber of the divided air-box, and also from the box under the second grate, are led away through suitable ducts.—B. N.

Metalliferous ores; Process for treating—
R. L. Lloyd, Assignor to Dwight and Lloyd Metallurgical Co., New York. U.S. Pat. 1,215,672, Feb. 13, 1917. Date of appl., Dec. 30, 1912. Renewed Nov. 1, 1915.

FINELY divided metallic sulphide ore is treated by air-blasting a stream of the ore into a confined chamber, and oxidising it at a high temperature to burn off the sulphur. Whilst in a "highly heated and nascent state," the particles are arrested before reaching the chamber exit and agglomerated, forming small molten bodies in which incipient smelting takes place, and they are then collected in a smelting bath, whilst the gases are withdrawn from the interior of the chamber.—B. N.

Furnaces for melting metals and for other purposes.

XII.—FATS; OILS; WAXES.

Linseed oil : Effect of heat and oxidation on —. J. A. N. Friend. Chem. Soc. Trans., 1917, 111, 162–167.

ON thickening Baltic linseed oil by heating (a) to 200° C. for 30 hours; (b) to about 300° C. for 36 hours; (c) to about 300° C. for about 12 hours without appreciable oxidation, the coefficient of expansion steadily falls and the density and viscosity rise with the temperature and length of treatment, whilst the molecular weight in benzene solution, calculated at infinite dilution, rises from 740 for the untreated oil to 760, 1000, and 1420 respectively. Linseed oil when exposed to oxidation as a thin film, loses very appreciable quantities of water, carbon dioxide, and organic vapours, so that the determination of the maximum increase in weight only represents a point of equilibrium at which the oxygen absorption counterbalances the loss due to escaping vapours, and there can be no proportionality between the increase in weight and the iodine value. Investigation of a sample of pure Calcutta linseed oil during the various successive stages of oxidation showed that the density of the oil gradually increased whilst the coefficient of expansion fell, there being an increase in volume up to the setting point of the oil, after which the linoxyn slowly contracted. The maximum increase in weight, 18.57%, took place after the oil had reached the setting point. The expansion is dependent on the increase in

weight, so that addition of substances to the oil which reduce the maximum increase in weight, probably by facilitating the escape of volatile substances, also reduces the expansion. The contraction suffered by linoxyn on prolonged exposure to air affords an explanation of the cracking of old paint.—T. C.

Soap : Detergent action of —. S. U. Pickering. Chem. Soc. Trans., 1917, 111, 86–101.

THE detergent action of soap must be attributed partly to its power of emulsifying oil, the globules of which become coated with a pellicle which prevents them from rendering adjacent objects oily; partly to the low surface tension between the soap solution and the oil; and possibly in part to the acid soap produced in the hydrolysis forming a colloidal compound with the dirt. The experiments cited show, however, that the main factor is that soap will dissolve oils, including paraffin oil, forming soluble compounds, some of which contain approximately equal proportions of oil and soap. In order to prevent the emulsification of a portion of the oil, the globules of which then become coated with a pellicle which prevents further combination with the soap, it is necessary to have a considerable excess of oil, if the soap is to combine with the maximum quantity of oil. The addition of water in excess does not decompose the oil-soap compound, but preliminary dilution of the soap solution causes more oil to be emulsified, with the result that a much smaller proportion combines with the soap. In the incorporation of oil with soaps three stages may be observed. For example, in the case of potassium stearate paste and benzene, the paste first becomes thickened owing to the oil being incorporated to form a coarse sort of emulsion; then the mixture becomes limpid owing to the formation of a soluble compound between the oil and the solid stearate; and thirdly this liquid rapidly solidifies to an opaque stiff mass owing to the globules of oil, through combination with the stearate, becoming sufficiently reduced in size to form a true emulsion. The extent to which these stages occur depends on factors such as the proportion of emulsion formed, the viscosity of the reagents, etc. The proportions of oil and soap which will unite depend both on the chemical and on the physical character of the reagents. For example, in the case of three samples of purified paraffin oils, the volumes dissolved of the oil boiling at 257° C., were intermediate between the volumes dissolved of the oils boiling at 98° C. and 198° C. respectively. Changes of temperature take place during the combination of the soap and oil, the nature and extent of the change depending upon the character of the oil. It is probable that the combination is invariably exothermic in character, but that the heat absorbed in the fusion of the solid stearate or semi-solid soap usually more than counterbalances the heat evolved. Naphthalene dissolves to a limited extent in soap, but partly separates out in crystalline form on cooling or diluting the solution. Soap will dissolve less paraffin oil in the presence of naphthalene.—C.A.M.

Oil of turpentine from Pinus pinaster: Italian —. M. Palazzo. Annali Chim. Appl., 1917, 7. 88—94. (See also this J., 1916, 1122.)

ITALIAN oil of turpentine is usually a mixed product of *Pinus pinca* and *P. pinaster*, Sol. Two pure samples of the oil from *P. pinaster* gave the following results:—Sp. gr. at 15° C., 0.867 and 0.871; n_D^{20} = 1.4700 and 1.4707; n_D^{25} = -35° at 26° C. and -35° at 23° C.; and flash point 33.5°C. The oil began to boil below 154° C., and from 151 to 163° C. yielded 85 to 90% of distillate. The only difference between the Italian and French oil from *P. pinaster* is that the former has a slightly higher optical rotation, the value for α_D for French oils ranging from -29° to -33°. The higher optical rotation of the Italian oil is due to the presence of a larger proportion of *l*-pinene. A commercial sample of the normal Italian product of mixed oils had the following characters: Sp. gr. at 15° C., 0.863; n_D^{20} = 1.4678; α_D = -48.15; flash point, 35.5° C.; and solubility in 90% alcohol, 1 in 5.1 at 25° C. When distilled it yielded 80% of distillate between 155° and 165° C. —C. A. M.

Coating materials: Preparation of dull-finish —. R. H. McKee, Orono, Me. U.S. Pat. 1,216,338, Feb. 20, 1917. Date of appl., Mar. 13, 1916.

A DULL-FINISH coating material is prepared by treating inferior grades of barium sulphate with concentrated sulphuric acid, then diluting the mixture gradually, and recovering the product. —W. P. S.

Pigment and method of preparing the same. H. A. Gardner, Washington, D.C. U.S. Pats. (A) 1,216,980 and (B) 1,216,981, Feb. 20, 1917. Dates of appl., July 11 and Oct. 26, 1916.

THE compositions claimed consist of an organic vehicle, and a pigment consisting of (A) an insoluble compound of zirconium (zirconium oxide) precipitated in presence of a base pigment the hiding power of which is inferior to, or its refractive index less than, that of zirconium oxide; (B) an insoluble compound of beryllium (beryllium oxide) precipitated in presence of a base pigment.—E. W. L.

Pigment and paint. L. E. Barton, Niagara Falls, N.Y., Assignor to Titanium Alloy Manufacturing Co., New York. U.S. Pat. 1,218,161, Mar. 6, 1917. Date of appl., Mar. 21, 1916.

THE pigment consists of particles of a sulphate base, with smaller particles of titanic oxide adhering thereto, mixed with white lead.—E. W. L.

Printing ink for stencil duplicating apparatus. J. Stevenson, and Roneo, Ltd., London. Eng. Pat. 101,429, May 30, 1916. (Appl. No. 7638 of 1916.)

THE ink contains calcium chloride as the hygroscopic substance, instead of glycerin, and may be composed of equal parts of a saturated solution of calcium chloride, and a 33 $\frac{1}{3}$ % solution of gum, to which 2 to 5% of lampblack or other inert colouring matter may be added.—E. W. L.

Rosin: Process for producing high-grade — from low-grade rosin. M. G. Donk, Washington, D.C. U.S. Pat. 1,219,413, Mar. 13, 1917. Date of appl., Apr. 1, 1915. (Dedicated to the public.)

THE light amber-coloured components are separated from the dark-coloured constituents of low-grade rosin by distillation at a pressure not exceeding 100 mm. and a temperature at which there is no material destructive distillation. The constituents of the distillate may be separated by fractional condensation. The still outlet is guarded with projections for preventing frothing of the heated rosin.—E. W. L.

Phenolic condensation product and process of making same. L. H. Baekeland, Yonkers, and A. H. Gottlieb, Hastings-upon-Hudson, N.Y. U.S. Pat. 1,217,115, Feb. 20, 1917. Date of appl., Oct. 17, 1913.

INFUSIBLE phenolic condensation products are prepared by heating a fusible phenolic condensation product with a sufficient proportion of a reactive methylene compound (anhydroformaldehydeaniline), which does not in the reaction yield a readily volatile by-product.—E. W. L.

Insulating compositions. U.S. Pats. 1,216,265 and 1,216,266. See XI.

XIV.—INDIA-RUBBER ; GUTTA-PERCHA.

Rubber Insulation Committee : Report of the Joint ——. J. Ind. Eng. Chem., 1917, 9, 310-317.

IN preparing the sample of rubber for analysis by the method described in the preliminary report (this J., 1914, 150), the insulation should be removed entirely from sufficient wire to give a sample weighing about 25 grms. This is ground to fine pieces in a No. 0 "Enterprise" coffee mill or similar mill, so that not more than 20% will pass through a 40-mesh sieve. The material is again sifted through a 20-mesh sieve, and what remains on the sieve is reground and again sifted, until the whole of the material has passed through the sieve. The wires of both sieves should be evenly spaced, in both directions, and should be 0.016 and 0.010 in. in diameter respectively. Any metal is then removed by means of a magnet and the sample is thoroughly mixed. The sampling should be done as soon as possible after vulcanisation, and, if possible, prior to saturation of the braid. When this is impossible the braid should be removed, and the insulation rubbed with sand paper to a depth of at least 0.005 in., and wiped with a damp cloth; but this treatment is not advisable, since it is liable to cause appreciable error in the acetone extract. The acetone extraction apparatus must be of the form and dimensions (in mm.) shown in the diagram. It should be heated so that the period

of filling an empty siphon cup with acetone and completely emptying it is between 2½ and 3½ mins. If there is any delay in starting the chloroform extraction after the extraction with acetone, the sample must be kept in a vacuum of at least 50 mm. of mercury. With regard to the specifications (*loc. cit.*), option is given to the purchaser to insert or omit the limit for total sulphur. Where such limit is omitted, certain sulphur-containing fillers may be used, whilst the use of man, kinds or an excessive quantity of reclaimed rubber would be guarded against by the limits for the various constituents of the acetone extract. For the determination of sulphur the following method is specified in place of the sodium peroxide method

described in the preliminary report:—0.5 gm. of the sample is treated with 20 c.c. of strong nitric acid to which has been added an excess of bromine, and the covered crucible allowed to stand for 1 hour, and then heated for an hour, after which the liquid is evaporated to dryness. The residue is fused with 5 grms. of a mixture of potassium nitrate and sodium carbonate (1:1); the melt digested with water for 3 or 4 hours on the water bath, the filtrate and washings (about 500 c.c.) treated with 10 c.c. of hot 10% barium chloride solution, and the barium sulphate filtered off after 12 hours.—C. A. M.

Cholesterols and phytosterols from the scientific and industrial point of view. A. Dubosc. Reprint from Caoutchouc et Gutta-Percha. 102 pages.

A SUMMARY is given of the constitution, properties, and compounds of the cholesterols and isomeric compounds. The presence of considerable quantities of phytosterols in the resins of indiarubber, etc., has caused attention to be directed to the means of utilising them industrially. Some years ago Morton proposed to utilise the resins of Pontianak for the production of isoprene, his method being based upon the fact that when cholesterol is heated in a tube in a current of hydrogen chloride, it is decomposed, with the formation of hydrochlorides of terpenes and water, and, on raising the temperature, of isoprene hydrochloride. This method, however, does not appear to have been used on an industrial scale. The fact that cholesterols are not affected by alkalis or basic substances has led Ellis to advocate their use for the preparation of protective varnishes for metal work in buildings. Soda-lime and potash-lime, however, decompose cholesterol at 250°C., yielding hydrogen and fatty acids. Cholesteryl stearate is prepared by heating a mixture of 1 part of cholesterol with 5 parts of stearic acid for 10 hours in a sealed tube at 200°C., and extracting the uncombined cholesterol with ether. It is prepared industrially from the resins of rubber, and is used as a substitute for animal and vegetable waxes in boot polishes. In the author's method of separating phytosterols from the resins of Jelutong rubber, the raw material is dried *in vacuo* at 100°C., which removes from 42 to 45% of water, and is then separated into an α -resin melting at 80–82°C., which can be extracted with acetone, and a β -resin melting at 105°C., which is soluble in ether and other solvents. They both have the formula $C_{24}H_{44}O$. The method of Lewkowitsch (this J., 1892, 134) is particularly suitable for the separation of cholesterol from other alcohols, but in the case of mixtures of cholesterol with mineral oil or tar the acetate method is preferable. The following method of determining the phytosterols in the acetone extracts of rubber is recommended. The residue left after evaporation of the acetone is boiled for 3 hours beneath a reflux condenser with 20 c.c. of acetic anhydride, which converts the phytosterol, lupeol, and α - and β -amyrols into their respective acetates. The acetic anhydride solution of the acetates is diluted with 100 c.c. of water and boiled for 3 hours beneath a reflux condenser to convert the acetic anhydride into acetic acid. The crystalline acetates are separated, washed with hot water, and boiled with 200 c.c. of standard alcoholic potassium hydroxide solution, the excess of which is titrated. Each gm. of potassium hydroxide neutralised by the acetic acid from the acetates corresponds with 7.393 grms. of phytosteryl acetate or 6.625 grms. of the resin. The di-iodide method is only applicable after the separation of waxes and tarry substances which may be present in the acetone extract, whilst the digitonin method is very accurate but requires the complete saponification of any esters of cholesterol which may be present.—C. A. M.

PATENTS.

Rubber latex; Coagulating—G. M. Thomas and M. D. Maude, Teluk Anson, Fed. Malay States. Eng. Pat. 104,323, Dec. 22, 1916. (Appl. No. 18,414 of 1916.)

LATEX of *Hevea brasiliensis* is allowed to coagulate spontaneously in vessels from which air is excluded. Such vessels are constructed with a trough running round their upper edge, and are provided with a lid with flanges dipping into the trough, thus forming, when the latter is filled with water or other liquid, a liquid seal which will permit of the escape of gases generated by fermentation, but will prevent the ingress of air. The vessel is filled nearly to the brim with latex, and the lid is then placed in position, the air pressure within and without being equalised by introducing a U-tube under the flange of the lid before water is poured into the trough, or by other similar device. Coagulation is complete within 24 hours, the coagulum being practically free from discoloration, and devoid of unpleasant smell.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning phenomena in jellies; Ultra-microscopic investigation of—W. Moeller. Kolloid Zeits., 1916, 19, 205–213. J. Chem. Soc., 1917, 112, ii, 132. (See also this J., 1917, 225.)

AN account is given of the ultra-microscopic structures which are exhibited by gelatin jellies when these are subjected to the action of alcohol, tannin, chromic salts, and formaldehyde. The micro-photographic records show that the phenomena associated with the action of these reagents on jellies are closely similar to those

which are characteristic of the tanning of hide fibres. The actual differences are due solely to the circumstance that the fibrils in the hide are orientated, whilst those in the jelly are distributed in all possible directions. It is assumed that gelatin contains two substances, α - and β -gelatin, of which only the α -gelatin forms the structural units, whilst the β -gelatin is structureless and occupies the spaces between the fibrils of α -gelatin. In the jelly these fibrils are independent of one another, and under the influence of external forces, the irregular net-work may be transformed into a system in which the fibrils are orientated, and in this way structures are developed which vary according to the nature of the forces to which the gelatin jelly is subjected.

Jellies; Internal and surface structures in—W. Moeller. Kolloid Zeits., 1916, 19, 213–219. J. Chem. Soc., 1917, 112, ii, 132.

THE author has examined the structure of gelatin subjected to the action of water vapour and warm water, of gelatin jellies before and after dehydration, and also the structure of gelatin which has been heated to a temperature at which it begins to decompose or has been subjected to the action of superheated steam and subsequently drawn out into threads. The observations afford evidence in support of the view that gelatin consists of an irregular conglomerate of fibrils forming a network of α -gelatin with β -gelatin in the intervening spaces. The structure becomes visible when the gelatin is subjected to any action which removes the β -gelatin partly or completely. In these circumstances the fibril units of α -gelatin undergo orientation to a greater or less extent, forming fibril groups which are visible in the ultra-microscope.

PATENTS.

Artificial leather, felt products, paper products, or the like; Manufacture of—T. Schmid and J. Foltzer, Horn, Switzerland. Eng. Pat. 101,536. Aug. 24, 1916. Under Int. Conv., Sep. 23, 1915. (Appl. No. 12,024 of 1916.)

RAW vegetable or animal fibrous material is carded, and passed through a cross-fleece or Blamire's apparatus, by which the fibres lying in the longitudinal direction and discharged by the doffer of the carding machine, are placed cross-wise and transversely. The web thus produced is passed between two pressure rolls, one of which has a wholly or partly roughened surface, and the other a rubber coating. By one of these rolls cellulose solution is delivered to the web from an underlying trough, and forced into the fleece by the pressure of the rolls. The fleece is then passed, preferably in a stretched condition, through a cellulose-hardening liquid, e.g., a solution of caustic soda or potash, or, for softer products, an acid bath. By using bleached fibre, and hardening with acid of 50°–60° B. (sp. gr. 1.53–1.71), a product similar to stiff Japanese paper is obtained. These products are impermeable to air, and where this is undesirable may be passed between needle rolls in order to provide them with artificial pores.—E. W. L.

Cork and leather substitute and process of making the same. U.S. Pat. 1,218,982. See V.

XVI.—SOILS; FERTILISERS.

Granitic soils; The forms of phosphorus in—C. Vincent. Comptes rend., 1917, 164, 109–111.

GRANITIC soils are generally supposed to be poor in phosphoric acid, on the ground that increased yields follow the application of phosphates in various forms. The application of lime or chalk,

however, has a similar effect, and the reason is that granitic soils are not really so poor in phosphoric acid, but a large proportion of it exists in organic combination with the humus and is not available until the latter has been neutralised. If these soils be digested near the boiling point with concentrated nitric acid for four hours, only a portion of the total phosphoric acid is found on analysis, but if the soil be first neutralised with lime, or dried and calcined, before digestion, the whole of the phosphoric acid is obtained; the difference may be very considerable. Under these conditions the granitic soils are found to be moderately rich in phosphoric acid and some of them very rich; in the majority of cases the application of a light dressing of lime, calculated for 1–5 years, combined if necessary with potash and farmyard manures, will suffice to make the phosphoric acid and a portion of the nitrogen readily available.—J. F. B.

Soil: Effect of irrigation water and manure on the nitrates and total soluble salts of the —. F. S. Harris and N. I. Butt. J. Agric. Res., 1917, 8, 333–359.

GLASS jars containing 800 grms. of a soil which had been preserved in the laboratory for 2½ years, were treated with varying amounts of water, and kept under observation from Jan., 1912, to Aug., 1911, any moisture lost by evaporation being replaced. It was found that the total soluble salts were at a maximum when the soil contained 29% of moisture, and the maximum nitrate-content was attained with 24%. The curves followed one another very closely, showing that the nitrates constituted the greater part of the soluble salts. A fertile loam soil rich in magnesium and calcium carbonates was potted in large galvanised iron tanks, in half of which New Zealand wheat was cultivated, the rest remaining fallow. The tanks were placed in a vegetation house and kept under treatment for over two years. In the cropped soils the initial moisture content was 15% and in the fallow about 22%. As the amounts of water increased, the quantities of total salts and nitrates both decreased, the nitrates being particularly low in a water-logged soil. Both constituents were much lower in the cropped than in the fallow soil. The optimum moisture content was 20–28% for the cropped soil. Field experiments were carried out during 1911, 1913–1915, in plots at the Grenville Experimental Farm, Utah, on a soil consisting mostly of fine sand, silt, and clay, which was of remarkable uniformity down to 10 ft., and which was rich in all plant nutrients except nitrogen. Dakota Sunshine corn (maize) was grown on the cropped plots. Under these conditions the nitrate content in both cropped and fallow plots was found to be greater during the summer than after the maize was harvested; it was higher in the fallow soil when 5 or 15 tons per acre of mixed horse and cow manure, fairly well rotted, was applied, than when no manure was given, the effect being most marked in the top 2–3 ft. of soil. On the cropped plots, 5 tons of manure produced no effect, but 15 tons increased the nitrate content. The nitrate content of manured soil was about three times as great with a fallow as with a cropped soil; in unmanured soil, about twice as great. Irrigation diminished the nitrate content in both soils, and the more water applied the lower the nitrate content. The total soluble salts were at a maximum in the fallow plots manured with 5 tons, and at a minimum with 15 tons; in the cropped plots the maximum was with no manure and the minimum with 5 tons. Irrigation reduced the content of soluble salts, particularly in the surface foot of soil, and this effect was greater in the cropped than in the fallow soil. The nitrates

were more affected by manuring and irrigation than the total soluble salts. The ratio of soluble salts to sodium nitrate in cropped soil rose from 21.5:1 without irrigation to 37.5:1 when 40 in. of water was applied; in the fallow plots the increase was from 8.9:1 to 16.2:1. The low nitrate content of soils under heavy irrigation is probably due partly to leaching and partly to diminished nitrification.—E. H. T.

Soil disinfection: New experiments on —. Miège. Comptes rend., 1917, 164, 362–365.

ON experimental plots measuring 20 sq. m. in a medium clay soil at Rennes, haricot beans, tomatoes, carrots, potatoes, and buckwheat were grown in presence of some or all of the following antiseptics: toluene, carbon bisulphide, hydrogen peroxide, lysol, formaldehyde, potassium permanganate, copper sulphate, sulphur, bleaching powder, and wood charcoal. The effects produced upon the crops were favourable and well marked, both from the standpoint of yield and from that of absence of disease. Thus with haricot beans, potassium permanganate and charcoal each produced a doubled crop, and the yield with bleaching powder was about 150% above that of the control. Bleaching powder increased the yield of tomatoes by nearly 50%, and the increased yields of carrots were about 150% with toluene or carbon bisulphide, and 200% with lysol or formaldehyde. Potatoes responded readily to all the antiseptics mentioned above, the increases varying from 50% with hydrogen peroxide, formaldehyde, or charcoal, to 100% with sulphur. The increases with buckwheat were considerably smaller. In a second series the effects of the same antiseptics, used mostly in combination, were observed upon tomatoes, and to a lesser extent upon cucumbers and carnations, grown in a soil that had been used continuously for 15 years, 6000 sq. m. being under glass and 1 hectare open field. The results were again favourable, the best resulting from the application of toluene or carbon bisulphide. In these cases the maximum yield of tomatoes was 3300 kilos. of fruit per plot (400 sq. m.); the lowest yield was obtained with copper sulphate—2100 kilos. per plot.—E. H. T.

Nitrates in soils: Phenoldisulphonic acid method of determining —. C. W. Davis. J. Ind. Eng. Chem., 1917, 9, 290–293.

THE presence of ammonia fumes does not affect the colorimetric determination of nitrates by the phenoldisulphonic acid method, but since light has an influence on the colour, the readings should be made without delay. It makes no difference to the results whether the reagent is applied hot or cold, or with or without stirring, nor does the temperature of the solution at the time when the alkali is added affect the results, except at freezing temperature, when it causes a slight loss. A loss of nitrates is caused by the presence of a chloride, whilst sulphates and carbonates reduce the loss. The presence of sodium acetate does not affect the results. No loss of nitrates occurred when potassium chloride was added immediately before the development of the colour with potassium hydroxide. In the method as ordinarily applied, a pronounced loss of nitrates takes place during the heating on the water-bath, but this may be prevented by keeping the liquid alkaline during the evaporation. The addition of 2 drops of hydrochloric acid to a solution containing 25 parts per million of nitrates caused a loss of all nitrates. When chlorides were present loss occurred on the addition of the phenoldisulphonic acid. This loss was prevented by evaporating the solution to dryness with an excess of calcium hydroxide, and by pouring an excess of phenoldisulphonic acid rapidly over the salt. It was

found that by the use of this modification it was possible to determine colorimetrically all the nitrates in a soil to which known quantities had been added. Ordinary alum may be used as a clarifying agent in preparing the soil solution, without risk of losing nitrates, but clarification with copper sulphate causes a great loss of nitrates.—C. A. M.

Ammonium salts; Characteristic effect of — on plant physiology. H. G. Söderbaum. Medd. No. 125 Centralanst. jordbruksförsök, Stockholm, 1915, 13. J. Chem. Soc., 1917, 112, i, 192.

PHOSPHATIC manures in the form of superphosphate, basic slag, and bone meal were applied to barley, with cross-dressings of sodium nitrate, ammonium sulphate, and ammonium chloride. Each plot was subdivided into three parts, two of which received also magnesium salts (one the carbonate and the other the sulphate), whilst the third received no magnesium. The ammonium salts caused considerable depression of growth, especially when used with superphosphate, and to a less extent when used with bone meal. The leaves yellowed, and some plants died. With basic slag, however, the results were different; all plots were normal, as were all those which received magnesium carbonate; moreover, affected plots recovered rapidly with applications of magnesium carbonate, but not with magnesium sulphate. The author attributes the physiological disturbances of the plants not so much to any physiological acid reaction of the ammonium salts as to an actual toxic effect produced by them.

XVII.—SUGARS; STARCHES; GUMS.

Glucose [; Determination of — in cane molasses]. H. Pellet. Ann. Chim. Analyt., 1917, 22, 43—47.

VAN EKENSTEIN and Lobry de Bruyn have shown that glucose, the non-fermentable reducing sugar formed from hexoses by the action of alkalis, occurs in cane molasses, and the author suggests procedure for determining its amount. 100 grms. of molasses, diluted about ten-fold and slightly acidified, is fermented for 3 days with 50 grms. of bottom-fermentation yeast, any pentoses present being destroyed under these conditions (cp. this J., 1916, 1075). The reducing power of the fermented liquid is determined at 63°—65° C. with a duration of heating of 30 mins., after defecation with normal lead acetate and removal of excess of lead by sodium carbonate. Assuming the reducing

power of glucose to be half that of invert-sugar, the author found in cane molasses quantities of glucose ranging from 2.6 to 5%.—J. H. L.

Pentoses; Influence of — in the determination of reducing sugars at 63—65° C. H. Pellet. Bull. Assoc. Chim. Sucr., 1916, 34, 21—24.

FOLLOWING the method of determining reducing sugars previously described (this J., 1914, 35), the author found that at 63—65° C. 0.05 gm. of arabinose reduced 0.095—0.100 gm. of copper in 10 mins., and 0.128 gm. in 30 mins. At 90—92° C. 0.05 gm. reduced 0.128—0.130 gm. of copper in 15 mins. In determining the joint reducing action of invert-sugar and pentoses at 63—65° C. it is therefore advisable to heat for 40 mins. Every operator should construct his own tables for these sugars under the conditions of working adopted, and determine also the corrections necessary when sucrose is present (cp. Maquenne, this J., 1915, 1263; 1916, 268, 320, 373).—J. H. L.

Cane molasses and vinasses; Determination of reducing sugars in — for the calculation of the amount of sugar fermented. H. Pellet. Bull. Assoc. Chim. Sucr., 1916, 34, 24—28.

THE non-fermentable matters of cane molasses exert a certain reducing action which, like that of sucrose (see Maquenne, this J., 1916, 268), increases considerably with the temperature. The influence of these substances may be minimised by carrying out the determination of reducing power at 63—65° C. (see this J., 1914, 35), heating for about half an hour to allow the pentoses and glucose to exert their full reducing action (see preceding abstracts). This procedure is specially recommended in determining the reducing substances in molasses and the corresponding vinasses, with a view to calculating the amount of sugar fermented, since usually the quantities of molasses and vinasses used for analysis do not correspond, and therefore contain different amounts of non-fermentable reducing substances.—J. H. L.

Mannose; Preparation of pure crystalline — and a study of its mutarotation. C. S. Hudson and H. L. Sawyer. J. Amer. Chem. Soc., 1917, 39, 470—478.

A METHOD is described for the preparation of mannose from vegetable ivory (from seeds of the tagua palm, *Phytolophus macrocarpa*), in which the material is hydrolysed with sulphuric acid, and a yield of 30—35% of the crystallised sugar is obtained without intermediate conversion into phenylhydrazone. The mutarotation of mannose is a unimolecular reaction. Its velocity constant increases about 2.6-fold for a rise in temperature of 10° C., and is independent of concentration below 10%, but increases above to a maximum at 45 grms. per 100 c.c. and decreases again beyond. Like that of dextrose, the mutarotation of mannose is accelerated by acids, and to a much greater extent by alkalis. It is doubtless due to a balanced action between α - and β -forms. Crystallised mannose is generally assumed to be the β -form.—J. H. L.

Achrodextrinase. Effront. See XVIII.

PATENTS.

Sugars; Process for decolorising —. J. J., J. C. N., and A. G. Eastick. London. Eng. Pat. 104,231, Mar. 8, 1916. (Appl. No. 3425 of 1916.) Addition to Eng. Pat. 5900 of 1914 (this J., 1915, 195).

IN decolorising sugar solutions by means of charcoal, acid is added at an early stage together with the charcoal, the proportion of acid being the maximum amount which can be used without

causing a degree of inversion during the decolorising process which would be detrimental to the finished product. Products containing 1—10% of invert-sugar suitable for many confectionery and preserving purposes, may be produced by this treatment with a considerable economy in charcoal. For good raw sugars a 50% solution should show an acidity of about $N/10$ concentration. —J. F. B.

Sugar: Process and apparatus for granulating and drying —. G. Engel, Brooklyn, N.Y. U.S. Pats. 1,216,554 and 1,216,555, Feb. 20, 1917. Date of appl., Nov. 10, 1915.

WET sugar is disseminated into an air passage and nearly dried sugar is disseminated into a second air passage; a relatively small body of cool air is passed through the second air passage in a direction opposite to that in which the sugar is fed, and the air from the second passage, with the addition of a large volume of warm air, is passed through the first passage in a direction opposite to the travel of the sugar in that passage, whereby the dry sugar dust from the second passage is intercepted by the moist sugar in the first. The apparatus comprises a rotary cylinder, means for breaking up the moist material to be granulated as it falls continuously within the cylinder, means for forcing warm air through the cylinder, a second granulating means adapted to receive the material as it is discharged from the cylinder, means for forcing a relatively small blast of air through the second granulating means and thence through the cylinder with the warm blast. —J. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Achrodextrinase. J. Eflront. Comptes rend., 1917, 164, 415—416.

CERTAIN species of *B. mesentericus*, cultivated in a nitrogenous medium, secrete an enzyme capable of liquefying starch. The best media for the production of the enzyme are feeding-cake, deprived of starch, and distillers' spent grains; from 1 kilo. of grains it is possible to obtain a quantity of the liquefying enzyme equivalent to that in 20 kilos. of good malt. The enzyme converts starch and erythrodextrin into achrodextrin very rapidly, but its saccharifying power is very restricted. If comparative conversions be carried out with soluble starch or starch paste at 40° C. until no further colour reaction with iodine solution is obtainable, the proportion of maltose produced by the bacterial enzyme is only about 40%, whereas with other diastases of vegetable or animal origin the proportion of maltose at the same stage is about 70%. Achrodextrinase is also characterised by the fact that the products of the conversion of starch paste, carried out at 50° C. until 42% of maltose is produced, possess a much lower viscosity than the products of the other diastases. Achrodextrinase is precipitated by alcohol and by ammonium sulphate; it acts most rapidly at 40° C. It is fully active in a medium neutral to methyl orange and is decidedly resistant to alkalinity, being still active in presence of 1 gm. per litre of sodium carbonate. On the other hand, it is very sensitive to an acid reaction, its activity being completely inhibited by the presence of 0.1 part of hydrochloric acid per 1000. The bacterial diastase may be substituted for malt in the textile industry, and may be used for the production of dextrin syrups from the residues

of starch factories. It may also be employed for removing starch in laundry work and a saving of 50% of soap may be effected by its use. —J. F. B.

Wines: White "cassee" of —. Fonze-Diacon. Comptes rend., 1917, 164, 199—200. (See following abstract.)

BOUFFARD in 1902 (compare this J., 1902, 922) described cases of white *cassee* in wine, characterised by the appearance of an opalescence and finally of a deposit which he concluded was due to oxidation and contained lime and possibly iron. The author investigated a white wine which showed this defect very strongly; the greyish-white deposit, formed after prolonged oxidation by means of a current of air, was found to contain organic matter, a small quantity of lime, and larger amounts of iron and phosphoric acid in proportion corresponding to $Fe_2O_3 \cdot 2P_2O_5$. This *cassee* only appears when the sulphurous acid, present in all white wines, has been oxidised, and the oxidising action of the air becomes effective. The use of sulphurous solutions of ammonium phosphate, employed at present in place of potassium metabisulphite in the manufacture of wines, appears to be one of the main causes of the appearance of this disorder. —J. H. L.

Wines: White "cassee" of —. J. Laborde. Comptes rend., 1917, 164, 441—443. (See preceding abstract.)

THE author has previously shown that the so-called white *cassee* or turbidity in wines is due to oxidation of traces of dissolved iron, from the ferrous to the ferric state, and their separation from solution as ferric phosphate which is often accompanied by other colloidal matters. This may take place in presence of free tartaric or even sulphurous acid, but when these are absent or present only in very small amounts the oxidised iron separates as tannate as well as phosphate and then produces black *cassee*. Treatment of wine with 0.5 gm. of citric acid per litre often prevents the appearance of white *cassee* and in other cases it promotes coagulation of the suspended particles. The best method of treating white *cassee* is as follows:—If the wine contains sulphurous acid it is aerated sufficiently to provoke the separation of all the ferric phosphate capable of being formed. Citric acid is then added and after standing for several weeks the wine is drawn off and clarified by means of finings or by filtration. Similar treatment may be applied in cases of blue *cassee* of red wines. —J. H. L.

Methyl alcohol [in ethyl alcohol]: Detection and determination of small amounts of —. E. Elvove. J. Ind. Eng. Chem., 1917, 9, 295—297.

SIMMONDS (this J., 1912, 150) recommended that the solution in which methyl alcohol was to be determined by the method of Denigès (this J., 1910, 585) should always contain 10% of ethyl alcohol. The author, however, finds that the test is rendered much more sensitive by reducing the proportion of ethyl alcohol to 0.5% by vol., as little as 0.1 mgm. of methyl alcohol in 5 c.c. then giving a coloration on standing for 40 mins. The following method of preparing Schiff's reagent for the test gives a much more stable solution than that obtained by the usual method:—Finely powdered Magenta (0.2 gm.) is dissolved in about 120 c.c. of hot water, and when cold the solution is mixed with a solution of 2 grms. of anhydrous sodium sulphite in about 20 c.c. of water, then treated with 2 c.c. of hydrochloric acid (sp. gr. 1.19), and diluted to 200 c.c. with water. After standing for about an hour the reagent is ready for use. A solution thus prepared gave the same results after six weeks, in the colorimetric determination of formaldehyde as

when freshly made. In the oxidation of the methyl alcohol with acid permanganate, it is necessary to allow the solution to cool before adding the reagent, since otherwise a deeper coloration is obtained. When formaldehyde is also present in the solution, it should first be determined by means of the reagent, and a series of methyl alcohol standards containing the same concentration of formaldehyde then prepared and used for comparison with the solution after oxidation of the methyl alcohol and treatment with the reagent.—C. A. M.

Enzyme: Non-specific character of the animal and vegetable reducing —. [Reductase.] A. Bach. Comptes rend., 1917, 164, 248–249.

EXPERIMENTS were made with milk and with potato-pulp to ascertain whether the reduction of nitric acid which these substances are able to effect in presence of aldehydes, is influenced by the nature of the particular aldehyde present. Fourteen aldehydes, fatty and aromatic, were tested, and the results, though showing quantitative differences, indicate that the action of the reducing enzyme is not specific in this respect.—J. H. L.

Phenol: Production of — by bacteria. A. Berthelot. Comptes rend., 1917, 164, 196–199.

THE author has isolated from human faeces a new species of intestinal bacteria, *B. phenologenes*, of which the power of producing phenol is about ten times as great as that of any other known bacteria. Cultivated in peptone-water it formed 0.278 grm. of phenol per litre, whilst in a liquid containing as organic matter only 2 grms. of tyrosine per litre, 0.8 grm. of phenol per litre was produced. The organism is capable of developing to some extent in presence of concentrations of phenol up to 6.8 grms. per litre.—J. H. L.

XIXA.—FOODS.

Wheat flour: Nitrogen in amino-form as determined by formal titration, in relation to some other factors measuring quality in —. C. O. Swanson and E. L. Tague. J. Amer. Chem. Soc., 1917, 39, 482–491.

PREVIOUS work at the Kansas Agricultural Experiment Station has shown that relatively large amounts of amino-nitrogen, whether artificially added in the form of amino-compounds, or produced by germination of the wheat, are detrimental to the quality of flour. The authors now present the results of determinations of amino-nitrogen by Sørensen's method, in the different "stream flours" from the same wheat in one particular mill, and in "patent," "clear," and "low grade" flours from a number of mills. The determinations were made by digesting 1 part of flour with 10 parts of water for 2 hours at 40° C., filtering, and titrating with N/20 barium hydroxide, first

directly for the original acidity, and then after addition of formaldehyde for the amino-nitrogen. The results show that the content of amino-nitrogen varies in general with the ash-content and the acidity, being much lower in "patent" than in "low grade" flours, but the differences are less marked because amino-nitrogen is more uniformly distributed throughout the wheat grain than mineral matter and acids.—J. H. L.

Wheat kernel: Phytic acid of the — and some of its salts. P. W. Bontwell. J. Amer. Chem. Soc., 1917, 39, 491–503.

FROM 2.5 lb. of wheat bran the author extracted, by a method based on that used by Clark (this J., 1914, 436), 25 grms. of phytin as a hygroscopic solid in spheroidal crystals, insoluble in water and free from inorganic phosphorus. Its composition indicated a calcium-magnesium salt not corresponding with any such salt of inositolhexaphosphoric acid, though containing equimolar proportions of carbon and phosphorus. The free acid was isolated as a hygroscopic solid which underwent some decomposition on drying *in vacuo*. The barium salt, crystallised from cold dilute hydrochloric acid, agreed in composition with an equimolecular mixture of the tri- and tetrabarium salts of inositolhexaphosphoric acid; crystallised from hot acid it possessed a rather different composition. Phytin extracted from wheat embryos appeared identical with that described above. The phytase of wheat bran exhibited greater activity in presence of 0.1% hydrochloric acid than in pure water or 0.2% hydrochloric acid, and its action was not affected by formaldehyde at 2% concentration. The enzyme was found present also in wheat embryos. Dry heating of wheat bran at temperatures from 105° to 165° C. increased the amount of inorganic phosphorus dissolved during subsequent extraction, without apparently destroying the phytase.—J. H. L.

Wheat offals: Composition and classification of —. T. B. Wood and R. H. Adie. J. Board Agric., 1917, 23, 1179–1187.

MUCH confusion has arisen owing to the variation in milling practice in different districts and to the fact that whilst the larger mills separate their products (offals) into four grades, many of the smaller mills are satisfied with a much less complicated separation. Systematic examination of a number of samples of offals showed that they differed from one another in size of particles and chemical composition. Nearly all millers take out the coarsest offals as *bran*, and the *flour* consists of particles which pass through silk sieves (No. 10) having 136 meshes to the linear inch; the remaining portion, which will not pass through this sieve, constitutes the *offals*. Offals fall approximately into three grades, namely:—Grade 1, usually called "fine middlings," which does not pass silk sieve No. 10, but passes silk sieve No. 3; grade 2, usually called "coarse middlings," which does not pass sieve No. 3 but passes wire sieve No. 24; grade 3, called "pollards," which does not pass wire sieve No. 24 but passes sieve No. 16. Bran is retained by wire sieve No. 16 (about 16 meshes to the in.). The following analyses show that this classification has a definite value:

	Water.	Protein.	Fat.	Carbo- hydrates.	Fibre.	Ash.
Fine middlings	12.73	15.75	3.41	63.80	1.86	2.42
Coarse middlings	13.46	16.12	5.03	56.22	3.29	3.58
Pollards	13.32	14.39	4.76	55.50	7.70	4.33
Bran	13.63	13.15	3.92	53.12	10.58	5.40

The quantities of carbohydrates and fibre increase continuously as the size of the particles becomes larger, but in the case of fat and protein, the largest amounts are found in coarse middlings, probably due to the concentration of the germ in this grade. The products from many mills, however, do not fall entirely in any one of these grades; some of them are mixtures of two or even three grades. Mixtures of grades 1 and 2 may be called "straight run middlings," of grades 2 and 3 "straight run pollards," of grades 1, 2, and 3 "straight run offals," and of grade 3 and bran "coarse pollards." The composition of these products varies according to the proportion of the grades present. It is suggested that millers should adopt a uniform system of grading and naming their offals, and that, whilst head trade names might be retained, each product should be sold under its grade number. For instance, fine middlings, which are sold in different districts under the names of seconds, fine thirds, biscuit middlings, etc., might still be sold under any one of these terms with the addition of the letters "S. G. 1" (standard grade 1) indicating that it is the finest grade of offals, separated between silk sieves Nos. 3 and 10, and so on. With such a system, a large number of samples might be collected and analysed and a definite standard composition assigned to each grade. W. P. S.

Silage: Relative influence of micro-organisms and plant enzymes on the fermentation of corn [maize]
— A. R. Lamb. J. Agric. Res., 1917, 8, 361—380.

DIFFERENTIATION between bacterial and enzymic activities during silage fermentation is extremely difficult, as the conditions favourable to both and the effects of such conditions are practically the same. The silage used in the investigation was made of chopped maize (*Zea mays*), which was packed tightly in cylindrical jars closed with rubber bungs carrying an outlet tube for the escape of gases and a pinchcock. The product so obtained differed in no essential from farm silage; it was pressed in a Buchner press and the juice was analysed for total acidity, volatile acidity (i.e., after distillation in steam free from carbon dioxide), alcohols (by two methods), total sugars, amino-nitrogen (Van Slyke's method), ammoniacal nitrogen (by distillation with magnesium oxide), and moisture. No conclusive results were obtained when silage was made in presence of certain antiseptics, but toluene seemed to stop all change, and chloroform prevented the development of bacteria. Equally inconclusive results attended the attempts to destroy the enzymes by heat and then to inoculate with infusion from normal silage; the treated material, however, showed marked changes. Silage containing tartaric acid, in amount (2%) sufficient to inhibit bacterial action but to favour that of yeasts, gave 1.76 grms. of alcohol per 100 c.c. of juice; normal silage gives 0.20–0.15 gm. A study of the curves representing the rates of chemical changes during fermentation led to more satisfactory results, inasmuch as the types of curve due to enzymic and bacterial actions are different. In purely enzymic actions the rate of change decreases as the action progresses, but where active organisms are present, the rate increases for a longer time owing to their multiplication. In this way it was found that the production of acid and the disappearance of sugar are due mainly to bacteria, and that the formation of alcohol and proteolysis are chiefly caused by the activities of enzymes, although in the latter cases, micro-organisms play a part in the later stages. The evolution of carbon dioxide is greatest during the first day or two, and nearly ceases after about four days. It is produced by enzymic action, assisted to some extent by bacteria and

yeasts after the period of greatest evolution. The rise in temperature within the silo is caused by micro-organic action, but enzymes possibly play a restricted part.—E. H. T.

XIXB.—WATER PURIFICATION ; SANITATION.

Bacteria in water: Direct microscopical counting of —. B. E. Nelson. J. Amer. Chem. Soc., 1917, 39, 515—523.

THE respective advantages of plating and direct counting, for the enumeration of bacteria in water, are discussed. The latter method occupies much less time than the former and gives an opportunity for the examination of other organisms present. In making direct counts with potable waters, it is first necessary to concentrate the bacteria into a small volume, for which purpose the author recommends adding to 1 litre of the water 1–5 c.c. of 5% zinc sulphate solution followed by 0.7–3.7 c.c. of N/1 sodium hydroxide. The organisms are trapped by the precipitate of zinc hydroxide and are concentrated with it to a small volume by sedimentation, filtration, or centrifuging. Practical details of all three methods of operating are given; the last is by far the most rapid, enabling counts to be started 15–20 mins. after the commencement of a test, but a method of filtration with sand, described fully in the paper, gives rather higher results. When the precipitate has been concentrated to 1–2 c.c., the zinc hydroxide can be redissolved by adding ammonium chloride, and after addition of a drop of alkaline Methylene Blue or clear "carbol-fuchsin," counting is proceeded with. Methods of making the counts are described. The results are more accurate than those obtained by plating, but are not directly comparable with them, as they commonly exceed them by 50–100% or more.—J. H. L.

Hypochlorite solutions; Volumetric method for determining the strength of ——. Analysis of hydrogen peroxide. A. Bury. J. Pharm. Chim., 1917, 15, 189—193.

A METHOD for determining the strength of hypochlorite solutions used for sterilising water in the field consists in measuring the volume of oxygen liberated when the hypochlorite is mixed with excess of hydrogen peroxide. The reaction proceeds according to the equation: $\text{NaOCl} + \text{H}_2\text{O}_2 = \text{NaCl} + \text{H}_2\text{O} + \text{O}_2$, and the volume of oxygen is equal to that of the chlorine which is liberated by treating the hypochlorite with an acid. One c.c. of the hypochlorite solution is placed in a graduated tube which is closed at the bottom and provided with a bulb and tubulure at the top; water is added slowly until the tube is nearly filled, followed by hydrogen peroxide up to the zero mark. The tubulure is then closed with a rubber stopper carrying a short length of capillary tube, the finger is placed over the outer end of this tube, the apparatus is inverted and its contents mixed. When gas is no longer evolved, the finger is removed slightly from the capillary tube. The volume of liquid which is forced out is equal to that of the oxygen liberated, and this volume is ascertained by placing the tube in its normal position and reading the volume of the liquid remaining in it. The tube is so graduated that the readings give directly the quantity of available chlorine in the hypochlorite solution. The reaction may be used, inversely, for the analysis of hydrogen peroxide.—W. P. S.

Infection from wounds; Prevention of ——. Comparative study of various antiseptics. H. Vincent. Comptes rend., 1917, 164, 153—156.

As a first-aid dressing for wounds, particularly those caused by shell splinters, a mixture of calcium hypochlorite, 10, and boric acid, 90 parts, was found to be the most efficient; it should be dusted over the surface of the wound, and does not produce any unpleasant sensation. It acts as a preventive against gangrene and also has a haemostatic action, due to the presence of calcium chloride in the mixture. Of other substances examined iodoform, ferrous sulphate, borax, boric acid, potassium permanganate, zinc chloride, and sodium formate were not sufficiently active to destroy the more resistant bacteria; copper sulphate and sodium fluoride were found to be effective, but their use is not recommended on account of their toxic properties.—W. P. S.

Carbonaceous dusts; Inflammability of ——. H. H. Brown. J. Ind. Eng. Chem., 1917, 9, 269—275.

TESTS were made with an apparatus devised by the Bureau of Mines, U.S.A., for testing the inflammability of coal dust, under the following standard conditions. All the dusts, with the exception of malt and two samples of maize dust, were first dried at 105°C . in a current of air. In each case 75 mgrms. was forced into the explosion bulb by air under a pressure of 20 cm. of mercury, through a funnel with a capillary 6 cm. long and 2.0 mm. in diam., a coarse screen being placed over the funnel except when very fibrous dust was tested. The funnel was 4 mm. in internal diam., with a bowl $\frac{3}{8}$ in. deep and $\frac{5}{8}$ in. across at the top, and having a bend at right angles, $\frac{5}{8}$ in. below the bowl, with a small wire screen inside. When used for coal dust 100 mgrms. of the more inflammable and 300 mgrms. of the less inflammable coals was introduced into the explosion bulb by means of oxygen under a pressure of 15 cm. of mercury. The temperature of the igniting coil, measured by means of a thermocouple, was maintained at 1200°C ., and the pressure generated on ignition was expressed

in lb. per sq. in. The following are typical results thus obtained, and indicate the relative order of inflammability under these conditions:—Lycopodium, 17.5; dextrin dust, 13.9; tan bark dust, 13.3; wheat starch, 13.1; maize dust, 12.5; powdered sugar, 12.2; oat dust, 12.0; potato flour, 11.7; rice starch, 11.3; malt dust, 10.6; tapioca flour, 10.4; cocoa dust, 9.9; fine sulphur flour, 8.8; ground cork dust, 7.4; arrowroot powder, 3.9; potato starch, 3.2; and gelatin dust, 1.4.—C. A. M.

PATENT.

Sewage and other liquids; Purification of ——. W. Jones, and Jones and Attwood, Ltd., Stourbridge. Eng. Pat. 104,187, July 11, 1916 (Appl. No. 462 of 1916.)

THE sewage enters at the end of a long tank divided lengthways down the middle and having a bottom of ridge and furrow form with air diffusers in the bottom of the furrows. The flow is directed by baffles and sunk walls to the opposite end, where the sewage turns at right angles into the other division of the tank, along which it flows in the reverse direction. Before being discharged from the tank, the sewage is received in a settling chamber with a bottom sloping towards the division wall of the tank. At this point, part of the wall is cut away to allow a connection to the other division of the tank. At the foot of the wall on the first division side is an air diffuser, and a shallow wall is built round the diffuser and both sides of the opening in the wall so as to form a well. When the air supply is turned on, an upward current of sludge and sewage is formed up that side of the wall, and a current of sludge and sewage is induced to flow through the opening from the other side. In this way sludge can be transferred from the exit to the entry end of the tank. At intervals along the base of the dividing wall are openings formed similarly to the foregoing; in this way sludge can be transferred from one side to the other along the whole length of the tank. In another form of the apparatus, instead of one long tank there are a number of short tanks arranged side by side and connected in series; in this form the tanks have a flat bottom and the air diffusers are placed at each end of the short tanks.—J. H. J.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Alkaloids; Determination of — by physico-chemical volumetric analysis. P. Dutoit and Meyer-Lévy. J. Chim. Phys., 1916, 14, 353—360.

THE method of measuring the end point of a reaction by observing the change in electrical conductivity (this J., 1911, 1411) may be applied to the determination of alkaloids, especially in very dilute solutions. The reactions available are: (1) neutralisation of the alkaloid bases, (2) the displacement of alkaloids from their salts by means of a strong alkali, and (3) precipitation of insoluble alkaloid salts. The neutralisation method is not usually very reliable, nor is the displacement method for soluble alkaloids. When the free alkaloid is insoluble or nearly so, the reaction of its salts with caustic soda gives a curve with a well-defined end point. Amongst the precipitants chlorplatinic acid and picric acid give satisfactory determinations of a number of alkaloids in the presence of sodium acetate; potassium bichromate in neutral solution may be used for brucine and strychnine. Silicotungstic acid in the presence of sodium acetate appears, however, to be the best general reagent. It is used in solution of N. 2 to

N 20 concentration conveniently standardised against a pure strychnine salt. The concentration of alkaloid should be between N 100 and N 1000. Two or three molecules of sodium acetate should be used for each molecule of alkaloid. The composition of the silicotungstate, which is not the same for all alkaloids, must be determined beforehand. Observing these conditions the authors have been able to use their method for twenty of the best known alkaloids. W. H. P.

Opium: Ammonia in. J. N. Rakshit. Pharm. J., 1917, 98, 255.

In determining morphine in Indian opium by the method of the British Pharmacopœia, an ammoniacal odour was always noticed on mixing the opium with lime in a mortar. Experiments described showed that this was due to the liberation of ammonia, amounting to 0.2–0.3% of the weight of the opium, together with traces of a volatile organic base not identified. J. H. L.

Chemical constitution and physiological action: Relation between in certain substituted amino-alkyl esters. F. L. Pymon. Chem. Soc. Trans., 1917, 111, 167–172.

ETHYL *p*-aminophenylacetate, m. pt. 51° C., prepared by the reduction of ethyl *p*-nitrophenylacetate, differs from ethyl *p*-aminobenzoate (anæsthesine) in containing a phenylacetyl group in place of a benzoyl group, and this substitution causes the loss of all local anæsthetic property. *β*-Diethylaminoethyl *p*-aminophenylacetate, obtained by heating the hydrochloride of *β*-diethylaminoethyl alcohol with *p*-nitrophenylacetyl chloride and then reducing with iron filings and acetic acid, differs similarly from *β*-diethylaminoethyl *p*-aminobenzoate (novecaine) and also possesses no local anæsthetic action. *β*-Diethylamino-*β*'-phenoxy-*iso*-propyl alcohol,

prepared by heating together phenylglycid ether and diethylamine in a sealed tube, gives a hydrochloride, m. pt. 90–92° C., which produces distinct local anæsthesia and on benzoylation yields *β*-diethylamino-*β*'-phenoxy-*iso*-propyl benzoate, which forms salts so strongly acid that they could not be satisfactorily tested for local anæsthetic properties. *β*-Benzoyloxy-1-methyl-1,2,3,4-tetrahydroquinoline, m. pt. 58–59° C., prepared by benzoylating 8-hydroxy-1-methyl-1,2,3,4-tetrahydroquinoline, gives a hydrochloride, m. pt. 188° C., too strongly acid to be tested for local anæsthetic action. The corresponding *p*-aminobenzoylethyl derivative could not be obtained. *p*-Aminobenzoylethyl-*p*-phenetidine, m. pt. 157–158° C., prepared by heating *p*-nitrobenzoylethyl chloride with *p*-phenetidine and subsequently reducing, is almost insoluble in water and produces no local anæsthesia when introduced as powder into the conjunctival sac.

Iodation of hydrocarbons: Direct — by means of iodine and nitric acid. R. L. Datta and N. R. Chatterjee. J. Amer. Chem. Soc., 1917, 39, 135–141.

MOXO-IODO derivatives of benzene, toluene, *o*-, *m*- and *p*-xylenes, mesitylene, and thiophene were prepared, with yields ranging from 30 to 80% of the theoretical, by heating mixtures of hydrocarbon, iodine, and nitric acid, the last being usually added in the concentrated form, a small quantity at a time. The nitric acid was reduced in the course of the reaction. Small yields of iodoheptane and iodonaphthalene were obtained similarly, nitronaphthalene being also formed in the latter case. Anthracene yielded no iodo derivative, but was oxidised to anthraquinone.

J. H. L.

Iodation by means of nitrogen iodide or by means of iodine in the presence of ammonia. R. L. Datta and N. Prosad. J. Amer. Chem. Soc., 1917, 39, 141–156.

IODATION of phenols and *o*-, *m*-, and *p*-nitrophenols can be conveniently effected by dissolving them in concentrated ammonia and adding iodine dissolved in potassium iodide solution. The iodo-compounds are in many cases precipitated quantitatively, and the reaction appears suitable for use on a large scale, since the excess of ammonia and iodine can be recovered from the mother liquors. Phenolphthalein is similarly converted into its tetraiodo-derivative, and *o*-, *m*-, and *p*-hydroxybenzoic acids yield iodo-compounds together with secondary products. A monoiodo-derivative is formed from *p*-hydroxyphenylarsinic acid. Dimethylpyrone yields 2,6-diiodolutidone as main product, together with iodoform due to rupture of the ring. The conversion of pyrrole in ammoniacal solution into tetraiodopyrrole,

can be employed for the volumetric determination of the former, using for example N/5 iodine solution and starch indicator. Nitrogen iodide, washed and suspended in water through which acetylene is bubbled, is completely decomposed with formation of tetraiodo-ethylene, m. pt. 185° C. Nitrogen iodide is a stronger oxidising agent than iodine; it oxidises quinol rapidly and completely to quinoxaline and benzaldehyde, with evolution of much heat to benzoic acid. Iodoform is produced by the action of nitrogen iodide on ketones in general, but if the reaction is carried out in concentrated solutions and at lower temperatures iodo-ketones are formed, some of which have an intensely irritating action on the eyes. Iodoform can be obtained by the action of iodine and ammonia on malonic and acetoacetic esters, and on di- and triethylamines.—J. H. L.

Ethylsulphuric acid reaction: The —. P. N. Evans and J. M. Albertson. J. Amer. Chem. Soc., 1917, 39, 456–462.

THE formation of ethylsulphuric acid in equimolecular mixtures of 99.9% alcohol and 95% sulphuric acid at constant temperatures between 20° and 140° C., was studied by withdrawing portions at intervals, diluting them with water, and titrating with alkali in presence of methyl orange. It is concluded that the maximum proportion of sulphuric acid converted into ethylsulphuric acid is about 58% at all temperatures between 20° and 100° C., and that this condition is reached in 150 mins. at 20° and in less than 2 mins. at 70° C. and higher temperatures. On addition of water the reaction undergoes reversal very slowly. Above 70° C. the esterification reaction is accompanied by formation of ether, which proceeds more and more rapidly at higher temperatures. At the ordinary temperatures there is a slow formation of diethyl sulphate (or isethionic or ethionic acid), as indicated by a loss of 4% of the acidity in three weeks.—J. H. L.

Fixation of nitrogen. Bucher. See VII.

Glycols: Manufacture of —. B. T. Brooks and L. Humphrey, Assignors to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,215,903, Feb. 13, 1917. Date of appl., Mar. 23, 1916.

GLYCOLS are obtained by heating dichloro-olefines under pressure with an alkali formate and an alcohol, e.g., methyl alcohol. The temperature may vary between 140° and 200° C. and the pressure from 100 to 260 lb.—B. V. S.

Lymph-gland extract and method of making same. R. A. Archibald, Oakland, Cal. U.S. Pat. 1,216,046, Feb. 13, 1917. Date of appl., Apr. 6, 1916.

THE aqueous extract of normal lymph glands of healthy animals is freed from antiferments by heating to 58° C. and from proteins and insoluble matter by treatment with weak acid and filtering. It is then carefully neutralised with caustic soda and sterilised; tricresol is used as a preservative. The extract is used by injection and stimulates the production and activity of leucocytes and blood-platelets.—B. V. S.

Hydrogenisation and dehydrogenisation of carbon compounds. C. Bosch, A. Mittasch, and C. Schneider, Assignors to Badische Anilin und Soda Fabr., Ludwigshafen, Germany. U.S. Pats. (A) 1,215,334 and (B) 1,215,335, Feb. 13, 1917. Date of appl., June 4, 1914.

XXII.—EXPLOSIVES; MATCHES.

"Nitron" as a gravimetric reagent for the analysis of substances used in explosives. W. C. Cope and J. Barab, J. Amer. Chem. Soc., 1917, 39, 504—514.

THE authors describe the various applications of

"nitron" (see Busch, this J., 1905, 289) in analysis, and add some new matter. For the determination of nitrates (see this J., Busch, 1905, 291, 638; 1906, 499; Gutbier, 1905, 158; Lange and Berl, 1905, 1190; Litzendorf, 1908, 83; Hes, 1909, 162; Franzen and Löhman, 1909, 546; Paal and Ganghöfer, 1909, 918), they found Gutbier's procedure most satisfactory. Busch's method for nitrocellulose (this J., 1908, 745) gave accurate results with this substance and with nitromannitol and nitrostarch, but with nitroglycerin it gave percentages of nitrogen about 0.4 too low; better results were obtained by a modified saponification process in which hydrogen peroxide of 30% instead of 3% concentration was used. True nitro-compounds cannot be determined in this way, but some of them form insoluble addition compounds with "nitron," and the authors determined picric acid (see Busch and Blume, this J., 1908, 83) and trinitrocresol accurately by precipitation with "nitron" in presence of sulphuric acid. Phenol and the mono- and dinitrophenols under the same conditions gave no precipitate, but in absence of sulphuric acid 1,2,4-dinitrophenol was quantitatively precipitated as a double compound, so that this substance could be determined in mixtures with picric acid. The authors determined perchloric acid in the same way as nitric acid (cp. Busch, this J., 1905, 291). Storm, and Burrell and Seibert (U.S. Bureau of Mines, Bull. 42) found that minute quantities of oxides of nitrogen in air could be determined, e.g., by shaking several litres of the air with 10 c.c. each of 5% potassium hydroxide and 3% hydrogen peroxide solutions, and precipitating the nitric acid in the usual way, avoiding unnecessary dilution. For microchemical tests with "nitron" see Visser, this J., 1907, 167. Solutions of "nitron" are not very stable and are best prepared in small quantities as required, by dissolving 1 gm. of the reagent in 10 c.c. of 5% acetic acid and filtering through an alundum crucible into a dark bottle. The reagent can be recovered from filtrates by precipitating with a slight excess of ammonia, and from precipitates by warming with dilute ammonia to 60° C., filtering quickly, and washing the "nitron" with cold water, then digesting with 5% acetic acid to dissolve it and finally re-precipitating with ammonia and washing. Decomposition may be avoided by conducting the filtering and washing in an inert atmosphere and as much as possible away from light.—J. H. L.

XXIII.—ANALYSIS.

Refractometer; Direct reading — with uniformly divided scale. G. W. Moffitt, J. Ind. Eng. Chem., 1917, 9, 305—309.

AN instrument is described by means of which the refractive index of a liquid is determined by placing a drop thereof on a convex surface, lowering the nose-piece of a microscope tube upon it, and focussing the eyepiece. The reading may then be made directly upon a uniformly divided scale on the focussing tube. Instead of the usual heating tank a circular trough may be provided, through

the centre of which passes a tube mounted on a spring, carrying the object scale at the lower end, and the lens on which the liquid is to be placed at the upper end, the lens being thus raised above the top of the heating jacket when the microscope is raised. At the lower end of the microscope tube is fixed a plane parallel plate, and within the tube at the right distance is a converging lens. With an eyepiece of fairly high power the degree of uncertainty in changing the setting for an alteration of refractive index from 1.000 to 1.500 need not exceed 0.02 cm. The theory upon which the construction of this instrument is based is discussed at length.—C. A. M.

Washing of gases: A simple apparatus for the —
H. H. Gray. Chem. Soc. Trans., 1917, 111, 179—183.

THE apparatus, designed to extract toluene from coal gas, is constructed so that a condensing mist of benzene vapour acts as absorbent. The gas is led in through the tube, A, and emerges laden with vapour of the solvent at E. The solvent (e.g., benzene) is heated to a suitable temperature in the flask, C, and at the conclusion of the extraction the mixture in C may be fractionated. The principal advantages over a train of washing bottles are: (1) greatly increased rapidity of washing; (2) absence of complications due to "back-pressure," and (3) limitation of the quantity of solvent required. The joints shown in the figure are mercury cup joints, but good

corks are quite satisfactory. —W. H. P.

Calorimetric combustion: Improvements in — and the heat of combustion of toluene. T. W. Richards and H. S. Davies. J. Amer. Chem. Soc., 1917, 39, 341—354.

SUCCESSIVE combustions of the substance under examination and of a standard substance are made in oxygen under about 22 atmospheres pressure, in a Berthelot bomb as modified by Atwater and Benedict (see Richards and Barry, J. Amer. Chem. Soc., 1915, 37, 993). The main improvements enumerated are grouped under the following headings. *Closing of the bomb.* A lead washer sunk into a suitable circular slot is used between the steel cover and the lower part of the bomb; the washer is covered by a continuous round plate of thin gold foil. Between the cover and the screw cap is a thin, smooth, flat ring of phosphor-bronze which avoids rupture of the platinum lining when closing the bomb. An improved method of insulating the current wire is also described.

Ignition of volatile liquids. These are weighed into very thin flat bulbs, and ignited by a ring of paraffin round the mouth of the crucible. This in turn is ignited by a tiny wisp of cotton wool which is heated in a platinum spiral. Iron wire is not used at all. *Control of temperature of environment.* The temperature rise of the calorimetric liquid is matched (after trial) in the surrounding bath (which is alkaline) by the automatically regulated admission of sulphuric acid. *Incomplete combustion.* This is greatly reduced by the method of ignition used, but in the case of volatile liquids it is controlled by determination of carbon monoxide in the products of combustion. Correction may also be necessary for the formation of nitric acid, though the bomb is always evacuated before the admission of oxygen. *Heat exchange between bomb and calorimeter.* If combustion is very rapid, the top of the bomb may become hot and heat be lost through radiation from the upper surface of the liquid. This is avoided by adequate stirring and by a rate of combustion similar to that adopted with the standard substance. With the above precautions and with naphthalene as standard, the heat of combustion of toluene is recorded as 19,158.18 calories or 42.47 kilojoules per gram (weighed *in vacuo*).—W. H. P.

Zinc: Electrometric titration of — with ferrocyanide. F. Russell v. Bichowsky. J. Wash. Acad. Sci., 1917, 7, 111—113.

THE single potential difference set up by a platinum electrode in a solution of potassium ferrocyanide, which can be measured in conjunction with a standard electrode, such as the normal calomel electrode, is about -0.08 volt. On titrating with a solution of a zinc salt, the potential increases slowly until near the end point, when the smallest excess of the zinc solution causes the E.M.F. to increase very sharply to -0.40 volt. With further excess the E.M.F. rises only slightly to a maximum of about -0.35 volt. If the process is reversed, and ferrocyanide admitted to the zinc solution, the platinum electrode, instead of having initially an E.M.F. of -0.15, can be made to assume almost any value between 0 and -0.5, depending on the previous treatment of the electrode. The abnormal values arising from polarization effects are dispelled by the presence of ferrocyanide, which gives rapid reversible reactions at the electrodes. If the electrode is charged to say -2.0 volts, while in contact with a zinc solution, the initial E.M.F. may reach the reversible value of -0.45 or even higher. After adjusting to this value, then titrating with ferrocyanide, the exact reverse of the previous curve is obtained, a sharp drop to -0.10 occurring at the end point, and continuing at nearly that value on further addition of ferrocyanide. If the platinum electrode has been treated to show an initial voltage of say 0.20 volt, on adding ferrocyanide, the E.M.F. increases instead of decreasing until the normal value is reached when, on continuing the titration, the reversible values are obtained as in the previous case. In all cases, if the solutions are stirred during the titration, the electrometric end point is perfectly sharp and reproducible and the device affords a convenient and accurate method for the estimation of zinc. —J. N. P.

Arsenic: Determination of small quantities of —. P. Klason. Arkiv Kem. Min. Geol., 1916, 6, No. 5, 1—16. J. Chem. Soc., 1917, 112, ii, 151—152.

THE author has investigated fully the Fresenius-von Babo method for the estimation of small quantities of arsenic. For the estimation, the substance was mixed with a mixture of 3 parts

of sodium carbonate to 1 part of potassium cyanide, and the mixture transferred to a bulb tube, the bulb having a volume of about 3.5 c.c. The bulb was heated by a ring burner, provided with a draught-chimney 20 cm. high, whilst a stream of carbon dioxide was passed through it. In order to prevent the arsenic subliming back, a piece of thick glass rod was put in the tube behind the bulb; the tube where the arsenic condensed was a capillary. In the first experiments, in accordance with the instructions usually given, the carbon dioxide was dried before passing through the tube, but it was found that this was not necessary. In later experiments the gas was simply washed and then passed through a tube containing cotton-wool, before coming to the bulb tube. The capillary tube must be quite clean and free from all traces of grease. When the deposition of arsenic was complete, the capillary tube was cut off and weighed on a micro-balance; it was then heated in an argand flame to expel the arsenic, and again weighed when cool, in order to determine the weight of arsenic. The results obtained, taking weights of arsenic oxide or sulphide varying between 0.0375 and 1.125 mgrm., were very variable and far from quantitative, the estimated quantities varying from 42% to 95% of the quantities actually taken. The loss was shown to be caused by some of the arsenic vapour being carried away in the stream of carbon dioxide. This was proved by attaching to the capillary of the bulb tube another (straight) tube packed with small bits of porcelain followed by a layer (3 mm.) of asbestos, this tube also ending in a capillary. During the estimation the asbestos layer became more or less dark, owing to the deposition of arsenic. When this arsenic was driven over into the capillary tube (in a stream of pure hydrogen) and its quantity estimated on the micro-balance, the amount found accounted for the low percentages mentioned above. By this means quantitative results could be obtained. A number of estimations of arsenic by the sodium carbonate-potassium cyanide method, as usually carried out (in Sweden) showed the accuracy to be about 90%. The reaction which takes place when the above reaction mixture is used cannot be simply the formation of potassium cyanate with the liberation of arsenic, since sodium carbonate is present. Reasons are given in support of the scheme: $5\text{NaAsO}_2 = 3\text{NaAsO}_3 + \text{As}_2 + \text{Na}_2\text{O}$. The sodium arsenate is then reduced by the potassium cyanide to arsenite, which again gives arsenate and arsenic, and so on to completion. It is further shown that if arsenic is present as a salt of ortho-arsenous or -arsenic acid, as is the case when magnesia is added to the reaction mixture, no reduction takes place. When the arsenic is present as sulphide, reaction takes place according to the equation: $\text{As}_2\text{S}_3 + 3\text{Na}_2\text{CO}_3 = \text{As}_2\text{O}_3 + 3\text{Na}_2\text{S} + 3\text{CO}_2$; reduction then takes place as above, no thiocyanate being formed.

The above method cannot be used when organic matter is present, but can be replaced by the following modification of Berzelius's method. The residues containing arsenic, if the latter is present as sulphide, are evaporated to dryness with concentrated nitric acid. The residue is then mixed with a mixture of equal parts of sodium carbonate and potassium carbonate and a little mercuric oxide, and the resulting mass put into the bulb tube and heated in a stream of oxygen until it is quite white and mercury is no longer deposited in the capillary. It is then reduced in a stream of hydrogen which has been purified by passing through dilute solutions of silver nitrate and mercury chloride. The arsenic deposited in the capillary is then weighed as given above. The temperature to which the bulb is heated should be such that the reaction mixture does not fuse. If fusion takes place and magnesia

is present, ortho-salts are formed, and these are no longer reduced by hydrogen, as mentioned above. Using quantities of arsenious oxide containing from 0.19 to 0.38 mgrm. of arsenic, good quantitative results were obtained.

Phosphorus: Dusart and Blondlot's method for the detection of — and its application in toxicology. Preparation of pure zinc for the detection of phosphorus or arsenic. H. J. Lemkes. *J. Pharm. Chim.*, 1917, 15 177–188.

CRITICAL examination of this method (formation of hydrogen phosphide by treatment with zinc and hydrochloric acid) showed that it could be employed for the detection of very small quantities (0.0025 mgrm.) of phosphorus in the form of phosphites or hypophosphites, provided that the gas first evolved was passed into silver nitrate solution, the precipitate of silver phosphide collected, again treated with zinc and hydrochloric acid, and the coloration of the hydrogen flame then observed. In dealing with phosphites, etc., the reduction proceeded most satisfactorily at about 55° C. The silver phosphide was not appreciably oxidised by contact with the excess of silver nitrate. There appeared to be no advantage in the spectroscopic examination of the hydrogen flame. In cases of poisoning by phosphorus, the method appears to be of use; the phosphorus is found chiefly in the stomach, remaining unoxidised for some few months, and phosphorus compounds do not appear to be formed during decomposition of the body. Pure zinc for use in the method may be obtained by fusing the metal with a small quantity of metallic sodium, followed by granulation (see Hehner, this J., 1902, 675).—W. P. S.

PATENT.

Gas analysing plant. Aktiebolaget Ingeniörsfirma F. Egnell, Stockholm. Eng. Pat. 103,107, Sep. 26, 1916. (Appl. No. 13,635 of 1916.) Under Int. Conv., Dec. 31, 1915.

Is a plant for simultaneously and automatically determining several gases in a number of gas currents, apparatus is provided for the determination of one gas in each current, and by means of multiple-way cocks, gas from any of these currents may be conducted to a separate apparatus, common to all or several of the currents, for determination of a second constituent.—J. E. C.

Trade Report.

Chemical and allied industries in France during the war; Survey of— F. J. Le Maistre. J. Ind. Eng. Chem., 1917. 9. 229—232.

THE author of this survey was a member of an American Commission which inspected the chief industrial centres of France in the autumn of 1916. As regards general plant it is pointed out that in many cases allowance has not been made for the expansion of the industries. The present inferiority of French chemical industry is to be attributed to: (1) lack of standard factory methods; (2) insufficient general knowledge; (3) lack of technical education; and (4) banking conditions. In the past the chemist has been confined to analytical work, and it is only since the war that the importance of industrial research laboratories has begun to be recognised. *Dyes.* In 1912 the quantity of coke produced in France was equivalent to 3,925,000 tons of coal, and that purchased to 2,817,000 tons of coal, corresponding to a total tar production of 505,250 tons. It is estimated that by the adoption of the standard German method France should have produced 53,177 tons of benzol or four to five times the quantity obtained in 1915. Pending the erection of more coke-ovens it is probable that there will be an opportunity for the sale of considerable quantities of American dyes in France. *Electrochemical industries.* Many new plants have been erected since the war started, but in the case of many of these cost has been sacrificed in the interests of larger production.

In the French Alps alone the horsepower development has increased from 500,000 to 1,500,000, and plans are being made for further extensions. *Atmospheric nitric acid.* Although the manufacture has been greatly developed during the last two years, the production is small as compared with other countries. Special attention is being given to the Serpek method of producing nitric acid from the air, in which bauxite is used as the raw material. The following figures show the amounts of calcium cyanamide in metric tons produced prior to the war:—

	France.	Germany.	Canada	World.
1912 ..	5000	22,000	32,000	105,000
1913 ..	7500	24,000	48,000	155,000

In 1916 the world's production was approximately 210,000 metric tons, the bulk of the increase being due to the fact that Germany, unlike France, has had to depend upon artificial nitrates. *Pharmaceutical chemicals.* The French law does not allow particular pharmaceutical compositions to be patented, and it is claimed that the French tariff has helped to develop the German manufacture of these products. A plan has now been worked out for developing the manufacture of these preparations and of synthetic perfumes, in which, owing to climatic conditions, French manufacturers should be able to maintain the lead. *Sulphuric acid.* France is now independent of any outside source of supply. The largest plants are in the South of France. *Paper industry.* France now produces the whole of the paper required by the country. The principal woods used in the mills are spruce, birch, and poplar. *Cement manufacture.* France has manufacturing capacity to supply her own requirements and those of her colonies. *Refining of sugar.* All refineries have to sell sugar at a fixed price. The by-product, molasses, is used for the production of alcohol, and the residues as a binding agent for road material. During the period 1903 to 1914 the manufacturing tax on beet sugar was reduced by 40% and the consumption increased by 61%. *Butter substitutes and table oils.* Copra, palm kernels, and arachis nuts are the raw materials used in the factories in the Marseilles district. *Soda industry.* In 1912 France imported 314,348 tons of soda, of which about 40,000 tons was used in chemical industries. During the past two years the output from both the soda and chlorine plants has been much greater than ever before.

—C. A. M.

Sweden: Prohibited exports.

THE exportation of the following articles from Sweden has been prohibited:—Accumulator plates; chrome alum; gold and silver, unmanufactured (and scrap) or manufactured, including gold and silver coin; nitric acid; paper coated with glue or other adhesive substances; and fly-papers consisting of such papers; Roentgen apparatus; rosia pitch, and wool fat pitch; copper and alloys thereof with zinc, tin, or other non-precious metal (such as brass, bronze, German silver, Britannia metal, etc.); also aluminium, nickel, and metals not specially mentioned in the Swedish Tariff (whether alone or in the form of alloys)—all these metals, unmanufactured or manufactured; lead, manufactures of, not previously prohibited; tin, manufactures of, not previously prohibited; zinc, unmanufactured, and manufactures of zinc.

Official Notices.

ANNUAL GENERAL MEETING, 1917.

In accordance with the provisions of By-law 64, notice is hereby given that the Annual General Meeting will be held in The University Buildings, Edmund Street, Birmingham, at 10.30 a.m. on Wednesday, July 18th, 1917. A programme of the proceedings will be issued later.

In accordance with the provisions of By-law 24, those members whose names are printed in *italics* in the List of Council will retire from their respective offices at the forthcoming Annual Meeting.

Prof. Henry Louis has been nominated to the office of President under By-law 20; Dr. Charles Carpenter has been nominated Vice-President under By-law 20; Mr. John Gray, Mr. A. R. Ling, Prof. R. F. Ruttan, and Mr. J. T. Wood have been nominated Vice-Presidents under By-law 21.

Members are requested to nominate on or before May 23rd next, fit and proper persons to fill four vacancies among the ordinary Members of Council. Forms for this purpose can be obtained from the Secretary of the Society.

By-law 23:—An Ordinary Member of Council shall be nominated by ten or more members upon Form B in the Schedule, a copy of which form shall be furnished by the Secretary upon the written or verbal request of any member, but a member shall not be eligible to sign more than one such nomination form, and the member nominated shall sign the declaration set forth on the form. A nomination shall be declared invalid by the Council if:

a. The member thereon nominated is disqualified or election, or ineligible to be elected, as provided by the By-laws.

b. The nomination is not made on the authorised printed form or substantially not in the manner directed thereon.

c. The nomination form is signed by less than ten members not disqualified or not ineligible to nominate as provided by the By-laws.

d. The nomination form is not received before the day appointed therefor.

e. The member nominated has not signed the declaration printed upon the form.

A member whose nomination aforesaid is declared to be invalid, shall receive notice thereof from the Secretary, and shall not be submitted for election.

J. P. LONGSTAFF,
Secretary.

REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY.

The first volume of these reports is now ready. As the issue is strictly limited, those who desire to obtain copies are advised to apply for them without delay. The price is 3s. to members and 6 to non-members, including postage.

PROHIBITED EXPORTS.

An Order-of-Council, dated 1st May, 1917, declares that the Schedule to the Proclamation, dated 10th May, 1916 (see this J., 1916, 620), amended and added to by subsequent Orders-

of-Council, prohibiting the exportation from the United Kingdom of certain articles to certain or all destinations,* should be further amended, as follows:—

* The prohibition of exports is as follows:—

Goods marked (A), to all destinations;

Goods marked (B), to all ports and destinations abroad other than ports and destinations in British Possessions and Protectorates.

Goods marked (C), to all destinations in foreign countries in Europe and on the Mediterranean and Black Seas, other than France and French Possessions, Russia, Italy and Italian Possessions, Spain and Portugal, and to all ports in any such foreign countries, and to all Russian Baltic ports.

(1) The following headings are deleted:—

(C) Animal hoofs and other glue stock (including untanned pelts and hides not otherwise specifically prohibited), fish bladders and fish skins; (C) Camphor; (B) Candles manufactured wholly or partly of paraffin wax or tallow; (C) Gums (except such as contain caoutchouc and except gum tragacanth); (C) Iceland, Irish and Sphagnum moss, algin and its compounds; Metals and ores, the following:—(A) Iron and steel plates and sheets except when made from crucible cast steel or from carbon steel not manufactured in the United Kingdom by the Siemens or Bessemer processes, provided such crucible or carbon steel does not contain more than 5 per cent. of chrome, cobalt, nickel, or vanadium; (B) Steel articles containing chrome, cobalt, nickel, or vanadium; (A) Steel flats, rounds and other sections, with the following exceptions:—(i.) When made from crucible cast steel; (ii.) Carbon steel for tools not manufactured in the United Kingdom by the Siemens or Bessemer processes; provided such crucible or carbon steel does not contain more than 5 per cent. of chrome, cobalt, nickel, or vanadium. (B) Oil, whale (train, blubber, sperm), seal oil, shark oil, fish oil generally, and mixtures of the foregoing; (B) Paraffin wax; (C) Resins, resinous substances (except such as contain caoutchouc) and articles containing resins and resinous substances; (C) Talc; (A) Tallow, refined; (B) Waxes, animal, mineral, and vegetable (except carnauba), and composite waxes.

The following headings are added:—(A) Aerated and mineral waters; (C) Algæ; (C) Algin and its compounds; (A) Beer and ale; (B) Camphor; (C) Celluloid, articles partly manufactured of; Chemicals, etc., the following:—(C) Calcium silicide. (B) Cinchona bark; (C) Fluorine compounds, not otherwise prohibited; (C) Iron, oxides of; (C) Manganese compounds, not otherwise prohibited; (C) Sodium silicate, and mixtures containing sodium silicate; (C) Vanadium compounds. (B) Glue stock of all kinds (including animal hoofs, untanned hides and pelts, not otherwise specifically prohibited, fish bladders and fish skins; (C) Gold paint containing sulphide of tin; (B) Gum arabic; (A) Gum, dammar; (C) Gums not otherwise prohibited; (C) Lichens; Metals and ores, the following:—(A) Iron and iron articles containing chrome, cobalt, molybdenum, nickel, tungsten or vanadium; (A) Iron, angle, channels, joists, tees and other sectional material; (A) Iron bars, including flats, rounds and other sections and shapes; (A) Iron billets, blooms and slabs; (A) Iron bridge work, pier work and constructional material; (A) Iron hoops and strips; (A) Iron ingots; (A) Iron pipes (wrought); (A) Iron plates and sheets; (A) Iron sheet bars; (A) Iron tubes; (A) Steel and steel articles containing chrome, cobalt, nickel, or vanadium; (A) Steel bars, including flats, rounds and other sections and shapes; (A) Steel plates and sheets; (A) Moss, Carrageen; (C) Mosses, other than

Carrageen moss; (A) Oil, sea-elephant, and mixtures containing such oil; (B) Oil, fish and seal, not otherwise prohibited, and mixtures containing such oil; (A) Oil, whale, and mixtures containing such oil; (A) Paraffin wax; (A) Caramel, liquid or solid; (A) Egg powder; (A) Resins, resinous substances (except such as contain caoutchouc) and articles containing resins and resinous substances; (A) Spermaceti; (C) Talc, all forms, including French chalk; (A) Tallow; (B) Waxes, animal, mineral, vegetable, and composite waxes, not otherwise prohibited; (A) Whalebone; (A) Whale fins; (A) Whalebone meal.

IMPORTATION AND DISTRIBUTION OF PETROLEUM.

By the requirement of the Government, the principal petroleum companies have arranged to poll their distributing facilities in this country and also the tonnage employed in bringing supplies to the United Kingdom, with the object of releasing men for the Army and effecting economy in various directions.

A Controlling Board, with Mr. E. Houghton Fry (Director of Munitions Petroleum Supplies) as Chairman, has been appointed by the Government, the Offices of the Board being at the Ministry of Munitions, 8, Northumberland Avenue, London, S.W.1. The Board will have the title "Pool Board, Petroleum Supplies," and will consist of representatives of the following companies:—The Anglo-American Oil Company, Ltd.; the Anglo-Mexican Petroleum Company, Ltd.; the Bowring Petroleum Company, Ltd.; the "Shell" Marketing Company, Ltd.; the British Petroleum Company, Ltd.; the Homelight Oil Company, Ltd.; the Union Petroleum Products Company, Ltd.; and Messrs. H. P. Wheatley & Company, Ltd. Mr. Alfred C. Adams will also be a member of the Board and will act as Chairman of the Distribution Committee.

All products, except lubricating oils, hitherto delivered under proprietary brands, will in future be delivered under war brands, and distributed under the authority of the Pool Board.

SEEDS, OILS, AND FATS. MINISTRY OF MUNITIONS ORDER.

The Minister of Munitions, in exercise of the powers conferred upon him by the Defence of the Realm Regulations, and of all other powers enabling him, hereby orders as follows:—

1. As from May 1st until further notice no person shall purchase, sell or, except for the purpose of carrying out a contract in writing existing prior to such date for the sale or purchase of any of the articles specified in the first schedule hereto, deal in any of the said articles whether situated within or without the United Kingdom except under and in accordance with the terms of a licence issued by or under the authority of the Minister of Munitions provided that—

(a) No licence shall be required

(i) By a seller for the sale of any of the said articles situated within the United Kingdom in quantities not exceeding one ton provided that the total quantity of all the said articles sold by him or on his behalf to or on behalf of any one purchaser during any one calendar month does not exceed five tons.

(ii) By a purchaser for the purchase of any of the said articles situated within the United Kingdom in quantities not exceeding one ton provided that the total quantity of all the said articles purchased by him or on his behalf

in any one calendar month does not exceed five tons.

2. As from May 1st until further notice no person shall purchase, sell or deal in or offer to purchase, sell or deal in any of the articles specified in the second schedule hereto at a price exceeding the price set opposite to the same in the second schedule. Provided that this restriction on price shall not apply to any sale or purchase of any of the said articles under which clause 1 of this Order is authorised to be effected without any licence issued by or under the authority of the Minister of Munitions.

3. All parties to any of the transactions herein specified shall require or disclose (as the case may be) all such information as may be necessary for or required by such parties as aforesaid or by or under the authority of the Minister for the purpose of satisfying them or him that the provisions of this Order have not been contravened.

3. All persons affected by this Order shall make all such returns as to stocks, purchases, sales, payments, prices and dealings in any of the articles specified in the first schedule hereto as shall from time to time be required by or under the authority of the Minister of Munitions.

NOTE.—All applications for licences under or otherwise with reference to this Order should be addressed to—The Controller of Oils and Fats, Great George Street, Westminster, S.W. 1.

First Schedule.

Seeds, nuts, and kernels. Castorseed. Copra. Cottonseed. Gingelly (sesame seed). Ground nuts. Hempseed. Kapokseed. Linseed. Mowrahseed. Nigerseed. Palm kernels. Poppyseed. Rapeseed. Shea nuts. Sunflowerseed.

Oils and fats. Acid oils (from refineries). Castor oil. Coconut oil. Cotton oil. Deal oil. Gingelly (sesame). Ground nut oil. Hempseed oil. Kapokseed oil. Linseed oil. Maize oil. Mowrahseed oil. Neutral lard. Nigerseed oil. Oleo oil. Palm kernel oil. Palm oil. Poppyseed oil. Premier jus. Rapeseed oil. Shea butter. Soya oil. Sunflowerseed oil. Tallow.

Second Schedule.

Palm kernels, £26 10s. per ton East Coast Ports, £26 per ton West Coast Ports, usual quay or ex ship terms. Palm oil, £44 per ton, usual Liverpool quay terms. Palm kernel oil, £52 per ton (crushed) net naked ex mill, £51 per ton extracted. Linseed, £30 per ton (Incorporated Oilseed Association Contract delivered terms). Cottonseed, £19 per ton (Incorporated Oilseed Association Contract delivered terms).

SALE AND PURCHASE OF WHALE OIL. MINISTRY OF MUNITIONS NOTICE.

By an Order made on the 24th June, 1916, the Minister of Munitions, in pursuance of the powers conferred upon him by Regulation 30A of the Defence of the Realm Regulations, ordered that the war material to which the Regulation applies should include whale oil other than sperm oil. The Minister of Munitions now gives notice that he hereby until further notice authorises and permits the sale and purchase and negotiation for the sale and purchase of whale oil (other than sperm oil) situate in the United Kingdom subject to the following conditions:—

1. No person shall either by himself or his agent in any consecutive period of three calendar months sell or purchase or negotiate for the sale or purchase of more than a total quantity of 25 tons.

2. No sale, purchase or negotiation shall be otherwise than for delivery within the United Kingdom.

NOTE.—All applications for permits under the above-mentioned Order of the 24th June, 1916, otherwise in connection with the said Order or this Order should be addressed to The Controller of Oils and Fats, Ministry of Munitions, Great George Street, Westminster, S.W. 1.

REQUISITION OF STOCKS OF QUININE, PHENACETIN, AND FORMALDEHYDE.

The Army Council has issued an Order dated April 28th, as follows:—

In pursuance of the powers conferred upon them by the Detence of the Realm Regulations, notice is hereby given that it is the intention of the Army Council to take possession of stores of the following classes and descriptions, that is to say:—

All stocks of quinine sulphate excepting stocks of less than 100 ounces.

All stocks of quinine bisulphate excepting stocks of less than 25 ounces.

All stocks of quinine hydrochloride excepting stocks of less than 25 ounces.

All stocks of quinine bi hydrochloride excepting stocks of less than 25 ounces.

All stocks of phenacetin excepting stocks of less than 7 lb.

All stocks of formaldehyde solution 40% excepting stocks of less than 10 gallons.

If after this notice any person without the consent of the Army Council sells, removes or secretes any of the said stores, or deals with it in any way contrary to any conditions imposed in any licence, permit, or order which may have been granted in respect thereof, he shall be guilty of an offence against the said Regulations.

All persons having in their custody or control any stocks of the said articles in excess of the said quantities hereinbefore set out, in the case of each article respectively are required to make a return of such stocks in the form indicated in Schedule A hereto annexed, to the Director of Army Contracts, Imperial House, Tothill Street, Westminster, S.W. 1, and any such further and other particulars as may be required by him or on his behalf.

SCHEDULE A.

List of Chemicals in stock.

To be filled in Name.....
by Firm. Address..... Date.....

Item.	Total stocks held.	Prices at which you will deliver to Army Medical Reserve Stores at Woolwich.	Average price at which you obtained your stock.	Date of last purchase.	Name and address of your last supplier.
quinine sulphate	ounces				
quinine bisulphate	"				
quinine hydrochloride	"				
quinine bi-hydrochloride	"				
phenacetin	lb.				
formaldehyde solution, 40%	gallons				

CAKE AND PASTRY ORDER, APRIL 18th, 1917.

The Food Controller orders that, except under the authority of the Food Controller, the following regulations, *inter alia*, shall be observed by all persons concerned:—

No person shall after the 21st April, 1917, make attempt to make for sale, or after the 24th April, 1917, sell or offer to sell or have in his possession for sale: (a) Any crumpet, muffin, tea cake or fancy bread, or any light or fancy pastries.

or any other like article. (b) Any cake, bun, scone or biscuit, which does not conform to the requirements of the two following provisions of this Order.

In the making of any cake, bun, scone or biscuit, no edible substance shall be added to the exterior of the cake mixture or dough after it has been mixed, or to the article during the process of or after baking.

Cake. No cake shall contain more than 15% of sugar or more than 30% of wheaten flour. *Bun.* No bun shall contain more than 10% of sugar or more than 50% of wheaten flour. *Scone.* No scone shall contain any sugar or more than 50% of wheaten flour. *Biscuit.* No biscuit shall contain more than 15% sugar. The percentage shall be determined in every case by reference to the weight of the baked article taken at any time. The percentage of sugar shall be ascertained by analysis of a sample representing a fair average of the whole article, and all sugar contained in the baked article shall be taken into account, in whatsoever form it may have been introduced.

The foregoing provisions of this Order shall not apply to any cake or biscuit proved to have been made before the 23rd April, 1917.

For the purpose of this Order the expression "Wheaten flour" shall mean any flour for the time being authorised to be used in the manufacture of wheaten bread, and the expression "sugar" shall include glucose.

THE MAIZE, BARLEY AND OATS (RESTRICTION) ORDER, MAY 2ND, 1917.

PROHIBITION OF MANUFACTURE OF GLUCOSE.

The Food Controller orders that except under the authority of the Food Controller the following regulations shall be observed by all persons concerned:—

1. (a) No person shall after the 9th May, 1917, use or treat any maize, barley, or oats or any product obtained from maize, barley, or oats or any article containing maize, barley, or oats or containing any such product except for the purposes permitted by this clause.

(b) The permitted purposes are seed, human and animal food and the manufacture of articles of food, but do not include the manufacture of glucose.

(c) This clause shall not apply to such products

and articles as on the 9th May, 1917, are unfit to be used in human or animal food.

2. No person shall after the 9th May, 1917, use or treat any tapioca, sago, manioc or arrowroot for any purpose except for human food or in the manufacture of articles suitable for human food.

3. Any person authorised by the Food Controller may take samples of any cereal, or other article which he has reason to suspect is being used or treated or is intended to be used or treated in contravention of this Order.

Editorial.

CYANIDES FROM ATMOSPHERIC NITROGEN.

An interesting chapter in the history of cyanide manufacture is recalled by the paper by J. E. Bucher, read before a recent meeting of the American Institute of Chemical Engineers, and abstracted in the last issue of this Journal (page 151). In this paper the author claims to have devised an economical process for manufacturing cyanide by causing atmospheric nitrogen to act on a mixture of sodium carbonate, graphite, and powdered iron at comparatively low temperatures (not exceeding 950° C.). He ascribes the success of his process to the recognition of the fact, first observed by Thompson in 1839, that the presence of iron lowers the reaction temperature very materially—a fact which has been neglected or discredited by other workers.

A number of attempts have been made to convert nitrogen into cyanides on a commercial scale, but the engineering difficulties consequent on the high temperatures required (about 1300° C.) have proved so great and have involved so much expense that they have all been abandoned.

As early as 1828 Desfossez observed that potassium cyanide was formed by the action of nitrogen on carbon and potassium carbonate. The first attempt to apply this reaction on an industrial scale was made by Possoz and Boissière, who worked their process (Eng. Pat. 9985 of 1813) at Grenelle, France, in 1813, and at Newcastle from 1811 to 1817. In this process a hot mixture of nitrogen and carbon dioxide was passed over wood charcoal which had been saturated with potash solution and dried, the charcoal being contained in fireclay retorts. This process had to be abandoned owing to the losses of potash and the short life of the retorts, and although it has been investigated many times since, no more successful results have been achieved. T. Ewan expresses the opinion that the difficulties due to the high temperatures required are insuperable, and mentions that the potassium cyanide is formed very slowly from potassium carbonate at 1350° C., a temperature at which most of the cyanide volatilises and at which potassium vapour is evolved from a mixture of the carbonate with carbon.

A process which requires a somewhat lower temperature than when potassium carbonate is used, is that discovered by Margueritte and De Sourdeval (Eng. Pat. 1171 of 1860), in which barium oxide or carbonate is used in place of potassium carbonate. L. Mond (Eng. Pat. 433 of 1882; also this J., 1889, 505) found that in this process cyanide is formed at 1200° C., but that the most favourable temperature is 1400° C.; the barium compounds fuse readily at this temperature, however, and attack fireclay rapidly, but this difficulty was overcome by briquetting the barium carbonate and carbon with a small quantity of pitch. By this method 40% of the barium was converted into cyanide. The process was abandoned, however, since Mond's object was to obtain ammonia, which he found was more satisfactorily produced by the action of air and steam on coal.

J. B. Readman (Eng. Pat. 6621 of 1891; this J., 1895, 35) applied electrical heating methods to this process with advantage, and his method was worked by the Scottish Cyanides Co. at Leven between 1899 and 1907; the financial results, however, eventually caused the process to be abandoned. A granular mixture of barium oxide and coke, produced by coking a mixture of barium carbonate and ground coal, was treated

with producer gas (containing 70% of nitrogen) in an electric furnace built of magnesia bricks, with carbon electrodes. The cooled product was lixiviated with water and the solution treated with sodium bicarbonate. It has been found that moderately complete conversion of barium oxide into cyanide can only be effected at temperatures below 1200° C. in presence of a very large excess of nitrogen, owing to the ease with which barium cyanide is decomposed by the carbon monoxide formed in the process. At 1100–1500° C., however, nitrogen fixation proceeds in presence of considerable quantities of carbon monoxide, but in this case a large proportion is fixed as barium cyanamide.

The Frank-Caro process should also be mentioned here, although it does not involve the direct conversion of nitrogen into cyanide. In this process the nitrogen is caused to combine with barium or calcium carbide, forming the cyanamide, which is then converted into cyanide, the barium salt by sodium carbonate and carbon and the calcium salt by sodium chloride.

In the experiments described by Bucher in the paper referred to above, satisfactory results were obtained by using briquettes made of soda ash, coke, and powdered iron, in equal proportions, without binding medium. When nitrogen was passed over these for half an hour at a temperature not exceeding 920° C., in a "batch furnace," the resulting briquettes contained 30% of NaCN. Considerable quantities of cyanide are formed even below 820° C., so that the process compares very favourable in this respect with the older processes, which required temperatures at least 300° C. higher, and generally more. Air, producer gas, the gas, or combustion gases give just as good results as when nitrogen is used in the process. Bucher describes a continuous furnace and an electric furnace in which he has obtained good results; brief descriptions of these have already been given (*loc. cit.*).

The essential feature of the process is the presence of iron; without it very high temperatures are needed. Iron appears to be the only catalyst which can be used with alkali carbonates. It is also necessary to mix the constituents of the charge thoroughly, and not to heat the briquettes so strongly that the iron melts into globules.

Whether Bucher has arrived at a satisfactory solution of the problem from a manufacturing standpoint remains to be seen; he does not give sufficient data as to yields and costs to enable any definite conclusions to be drawn on the point, though from the details given the results certainly appear to be promising. (See also this J., 1913, 913; 1915, 716.)

Meeting held at Nottingham on Wednesday, April 4th, 1917.

DR. R. M. CAVEN IN THE CHAIR.

THE STANNOUS CHLORIDE REDUCTION METHOD FOR ESTIMATING NITROTOLUENES.

BY LEUT. E. DE W. S. COLVER AND DR. E. B. R. PRIDEAUX.

In order to prepare the way for investigations upon mixtures of nitro compounds, the authors have had occasion to try some experiments upon the determination of NO₂ in such compounds by reduction. These notes of the results are pub-

lished in the hope that they will save some preliminary work to others who are undertaking similar researches. The method of Knecht and Hibbert suggested itself, in which the nitro compound is reduced by boiling with titanium trichloride, and the unoxidised part of this estimated by titration with iron alum and thiocyanate indicator. By boiling for some time in an atmosphere of carbon dioxide, good results were obtained from picric acid and *p*-nitraniline. Nitro compounds which are insoluble in water or acids must be previously sulphonated (*e.g.*, nitrobenzene) or dissolved in alcohol before boiling with the titanium trichloride (*e.g.*, *m*-dinitrobenzene). The necessity for sulphonation detracts from the convenience of the process, and in the case of the mono derivatives it is more than doubtful whether reduction would proceed in the presence of alcohol (see below, p. 482). Also titanium trichloride of suitable purity is not always to be obtained at short notice.

It did not appear that the older stannous chloride reduction method had been thoroughly investigated from the point of view of accuracy, nor were the conditions as given in the original papers found to be clearly defined or in complete agreement. The following is an outline of the method: About 150 grms. of tin is dissolved in sufficient hydrochloric acid, cooled, the solution decanted and made up to one litre. Solutions of 90 grms. of anhydrous sodium carbonate (or hydroxide) and 120 grms. of Rochelle salt in one litre, and of decinormal iodine are also prepared. About 0.2 grm. of the compound is treated with 10 c.c. of the stannous chloride solution in a 100 c.c. flask. After the mixture has been warmed for some time it is cooled quickly and made up to the mark with distilled water. Of this solution 10 c.c. is treated with the alkaline tartrate until the white precipitate first obtained is dissolved, and then titrated with iodine and starch indicator.* The results given in Altmann's paper are satisfactory for salts of sulphonated nitro compounds. By titration of the excess stannous chloride with permanganate instead of iodine, concordant results were obtained also for *o*-nitrophenol and *m*-dinitrobenzene. There was a considerable difference, however, between the stannous titre as determined by iodine and by permanganate, and these two sets of numbers were not in a constant ratio but varied with the volume of permanganate required. The method does not seem promising, especially in view of the observation of Altmann that the permanganate oxidises an acid solution of naphthylamine to a considerable extent. Finally it was found that good results were obtained for nitro-anilines and nitrotoluene after reduction for several hours in a sealed tube and with the addition of ferric chloride before titration. By the original alkaline tartrate method outlined above the following results were obtained with trinitrotoluene. When warmed with the stannous chloride the compound dissolves very slowly. If previously dissolved in alcohol and precipitated with stannous chloride it dissolves quickly on warming. In both cases the solution is yellow or orange in colour. The titration with tartrate gives results which are variable and very low. In most cases the end-point was indefinite, the blue of starch passing continuously into yellow or brown. The same appearances were observed with dinitrotoluene and a pure sample of Kahlbaum's metadinitrobenzene. The yellow solution probably contains a hydroxylamine compound. A solution of similar colour but somewhat browner is obtained by reduction of trinitrotoluene with zinc and ammonium chloride and addition of concentrated hydrochloric acid.

The reduction was then carried out at 100°. The same yellow colour was at first obtained, but in a few minutes the solution became colourless. Subsequent heating for a quarter of an hour or half an hour produced a faint brown colour, but it was afterwards found that this did not materially affect the analytical results. After this more lengthy reduction the alkaline tartrate titration gives a better end-point. In any case the addition of alkaline tartrate has to be carried out carefully, and at a rate varying with the ratio of hydrochloric acid to stannous chloride in the solution, in order to obtain a precipitate and then redissolve it. It would be desirable to avoid it if possible. Experiments were therefore made in order to find whether a direct titration with iodine in acid solution was feasible, and this was found to be the case, with certain precautions which are indicated below. The results agree with the highest obtained by the alkaline tartrate titration and seem to be more concordant than the latter. It seems probable that the tendency to use up iodine by substitution in the amines may be greater in the neutral or alkaline than in the acid solution. Another advantage of the acid method is that any alcohol added to dissolve the organic compound is unaffected by the iodine, whereas in the tartrate solution the alcohol may be attacked to a certain extent.

Procedure.—Such a weight of the compound is taken as will be reduced by about 10 c.c. of the 2 to 2.5-N stannous chloride. Of this, 20 c.c. is then added to the compound in a 100 c.c. flask and 10 c.c. for a blank to another 100 c.c. flask. Accuracy in measuring the concentrated stannous chloride solution is important. The relations between the volumes of the 10 and 20 c.c. pipettes, and also between those of the flasks and the pipettes and burettes used in the subsequent titrations, should be accurately known. The flask containing the blank stannous chloride may be heated, shaken, etc., in much the same way as the experimental flask, and under these conditions a special experiment showed that the difference in the atmospheric oxidation of the two quantities was negligible. It may be mentioned here that the stock solution loses strength at the rate of about 0.25% per day, and the approximately 0.2-N solutions after making up to 100 c.c. in the flasks at the rate of about 1% in 24 hours.

The sample, weighed accurately to within a milligram, is placed in the flask with the stannous chloride and about 3 c.c. of concentrated hydrochloric acid. The flask is then placed in boiling water and shaken. A bright yellow colour usually develops in the case of di- and tri-nitro compounds, which vanishes in a few minutes, leaving the solution colourless. If a slight yellow colour remains the acid titration still gives concordant results. After cooling and making up to 100 c.c. the blank and sample are diluted with water and titrated with iodine at the rate of about 2 drops per second. It is best to repeat the titration of blank and experimental solutions several times and take the mean of the results. One blank may be taken as giving the factor of the stannous chloride with sufficient accuracy for the duration of a working day, unless of course some experiments are performed under conditions far removed from the normal procedure. It is important to add the iodine at about the same rate to the sample as to the blank, since it was found that in both cases the iodine required was less for a slow titration than for a quick one. If the iodine is added in a continuous stream to the pure stannous solution, the results of the acid titration agree most closely with those of the alkaline tartrate titration. The iodine used in these titrations was controlled by resublimed iodine, by potassium bichromate,

* Altmann, J. prakt. Chem., 1911, 63, 379; this J., 1901, 622.

and sometimes also by arsenious oxide. The results were calculated as follows:—

(A) 10 c.c. of blank needs 21.75 of iodine (mean).

(B) 10 c.c. of solution needs 21.95 of iodine (mean). Ratio of 20 c.c. pipette (B) to 10 c.c. pipette (A)=1.97. Ratio of 100 c.c. flask (B) to 20 c.c. pipette=5.06. Hence total iodine equivalent to stannous chloride taken in (B)=21.75 × 1.97=42.85. Iodine equivalent of stannous chloride not used for reduction=21.95 × 5.06=111.1, and iodine equivalent of stannous chloride used for reduction=42.85=111.1=317.4.

Weight of T.N.T.=0.1200 gram. Factor of iodine=1.001.

Hence c.c. of normal iodine equivalent to one gram. of T.N.T.

$$\frac{317.4 \times 1.001}{0.1200 \times 10} = 75.67.$$

Compounds investigated.

The trinitrotoluene was recrystallised from the refined as well as from the crude product by the use of different solvents. The melting points as determined by a standard short range thermometer graduated in $\frac{1}{10}$ were between 80.2° and 80.8°. The weights of the compound taken for 20 c.c. of the stannous solution varied from 0.3 to 0.4 gram. The dinitrotoluene was recrystallised either from benzene and petroleum ether (hot) or from alcohol. The melting point on the same thermometer was from 69.9 to 70.1°. The weights taken varied from 0.38 to 0.42 gram. The mononitrotoluene used was the *p*-compound, possibly containing some *ortho*. The melting point as determined by a similar thermometer of different range was from 50.5° to 50.75°. Rintoul* gives 51.6° to 51.9° as the melting point of the pure para compound.

In the case of dinitrotoluene the reduction follows much the same course as with the trinitrotoluene. The acid titration may be carried out after a quick reduction, while for the alkaline tartrate titration the solution should be kept at nearly 100° for at least a quarter of an hour.

In the case of the mononitrotoluene reduction is much slower and does not proceed at all in the presence of some alcohol. The flask should be provided with a glass stopper and kept closed during the early stages of the reduction. There is little if any yellow colour at any stage. Reduction should be continued until there is no more smell of nitro compound.

The results for tri- and dinitrotoluenes are expressed in Tables A and B, referring to two different series carried out with entirely different reagents and apparatus. This serves as a check on their reproducibility.

The uniform lowness of the results does not seem to admit of a sufficient explanation without further work. By the acid titration, the stannous chloride used appears to reach a limit as soon as the solution becomes colourless, i.e., in a few minutes. Where the solution is kept at 100° for $\frac{1}{4}$ to $\frac{1}{2}$ an hour, and a good end-point is obtained, the results of the tartrate titration in general agree with the acid titration, both iodine figures (blank and sample) being higher. Various explanations, such as the constant presence of some impurity in the nitro compounds, the substitution of iodine in the amine during titration, etc., have been considered, but there are difficulties in the way of all.

The possibility of a constant error in the iodine titration was to some extent tested by titrating the excess of stannous chloride also with decinormal iron alum (factor 1.08) until the solution was faintly yellow, and gave a pink colour with a drop of ammonium thiocyanate solution. For 10 c.c. of the solution containing the reduced trinitrotoluene 18.3 c.c. of ferric solution was required, and for 10 c.c. of the blank 21.5 c.c. The weight of trinitrotoluene was 0.3530 gm., and the titrations with iodine gave 74.0 and 76.2 c.c. of normal oxidising solution equivalent to 1 gram (Table B), the value now found by means of the ferric solution being 75.5. A similar experiment was carried out with 0.3936 gm. of dinitrotoluene, the solution and blank being made up exactly as in previous experiments. For 10 c.c. of the amine solution 19.45 c.c., and for 10 c.c. of the blank, 21.1 c.c. of the ferric solution were required. The number calculated from these results is 62.5, again agreeing well with the mean of the iodine values. The ferric titration is in some respects better than the iodine, and serves as a useful check on the latter.

The agreement of these results could no doubt be considerably improved by a worker who was examining a larger number of samples in a uniform manner. It seems, however, that the method as it stands does not compare altogether unfavourably with the determination of NO_2 as N_2 by combustion. This was considered by Altmann to be inapplicable to nitro compounds. In point of speed there is no comparison between a nitrogen combustion and the direct acid titration, which can easily be completed in half an hour when all solutions, etc., are ready.

The object of the research was, however, to find whether sufficiently constant numbers could be obtained to allow a calculation of the percentage composition of binary mixtures, and it seemed that this should be possible.

Mixtures of dinitrotoluene and trinitrotoluene.

Some known mixtures of the pure compounds described above gave the following results:—

Iodine equivalent of the trinitrotoluene, 75.6, and for dinitrotoluene, 63.0. For a mixture of 0.1612 gm. of trinitrotoluene and 0.2430 gm. of dinitrotoluene the iodine equivalent was 68.1 % of dinitrotoluene calculated from iodine = 59.5, and % of dinitrotoluene taken = 60.2, or taking the mean values of iodine numbers of trinitrotoluene and dinitrotoluene, the % of dinitrotoluene calculated is 59.2.

Mixtures of dinitrotoluene and trinitrotoluene.

A mixture of 0.2354 gm. of trinitrotoluene and 0.1582 gm. of dinitrotoluene had an iodine equivalent of 70.44. The mean value for dinitrotoluene is 62.82, and for trinitrotoluene 75.50. Hence percentage of dinitrotoluene calculated is 40.0 and of dinitrotoluene taken = 40.25 %.

Mixtures of mononitrotoluene and dinitrotoluene.

A mixture of 0.2053 gm. of dinitrotoluene and 0.3058 gm. of mononitrotoluene gave iodine

equivalents of 50.1 (acid titration slow), 50.6 (acid titration quick), and 50.2 (tartrate titration).

Hence taking the mean values for D.N.T. and M.N.T., the percentage of mononitrotoluene calculated = 58.3, and the percentage taken = 59.8. The slow acid titration gives 58.7 %.

This work was carried out partly at the Research Department, National Shell Filling Factory, Chilwell, and partly at University College, Nottingham.

SOME NOTES ON AMMONIUM THIOSULPHATE-POLYTHIONATE SOLUTIONS; A CONTRIBUTION TO LIQUID PURIFICATION OF COAL GAS.

BY E. V. ESPENHAHN, MELBOURNE.

Investigations in the direction of the polythionic acids have proceeded from the mixture of these acids in the Wackenroder solution. Debus* carried out an exhaustive research on the potassium salts and proved the existence of pentathionic acid, which was later confirmed by other investigators.

The salts of these acids assumed technical importance with the introduction of the Feld process† for the recovery of ammonia and sulphuretted hydrogen from illuminating and coke-oven gas. His solutions of the zinc and iron polythionates with thiosulphate were superseded by the simpler and more effective ammonium thiosulphate-polythionate washing solution. This solution consists of ammonium thiosulphate which is treated with sulphur dioxide and forms polythionate, when it is brought into intimate contact with the gas in rotary vertical washers. The reaction with the polythionate results in the absorption of the ammonia and part of the sulphuretted hydrogen. As the solution becomes concentrated, portion is withdrawn, treated with more sulphur dioxide and heated, whereby the polythionates are converted into sulphate. By evaporation a salt suitable for fertilising purposes is recovered, and the process claims to solve the problem of utilising the sulphur contained in the coal for the fixation of ammonia without first forming sulphuric acid.

The following investigations were carried out by the author:—

- (1) The reactions occurring between thiosulphate and sulphur dioxide.
- (2) The reactions between ammonium polythionate and ammonia.
- (3) The reactions between ammonium polythionate + free sulphur dioxide and ammonia at 100°.
- (4) The reactions between ammonium polythionate + free sulphur dioxide and ammonia and ammonium sulphide at 100°.
- (5) Application of the reactions to the industrial process.

1. Reactions between thiosulphate and sulphur dioxide.

An ammonium thiosulphate solution may be prepared by the action of sulphur dioxide on ammonium sulphide, according to the equation:—

The sulphur is precipitated in the amorphous form as a flocculent mass, but a portion remains in solution, which is precipitated in the colloidal form on heating the solution to 100° C.

* Debus, Annalen, 1887, 244, 76—190.

† W. Feld, Z. angew. Chem., 1912, 20, 705. This J., 1912, 430.

On further addition of sulphur dioxide polythionates are formed; this reaction has been considered by Feld as being:—

or as:—

The analogous reaction with potassium thiosulphate has been stated by Debus to proceed according to the equation:—

which it was considered might also apply to the reaction with the ammonium salt.

The determination of any two of the polythionic acids in the presence of thiosulphate may be carried out by titrating the sulphuric acid formed by the oxidation of these acids with mercuric chloride and alkaline hydrogen peroxide.* Thiosulphate is determined with standard iodine. The radicles may be calculated from the following values:—

1 c.c. of 1 grm. mol. per l.	c.c. N/10 iodine.	c.c. N/10 NaOH with	
		HgCl ₂ .	alk. H ₂ O ₂ .
S ₂ O ₃	10	20	20
S ₃ O ₆	—	40	40
S ₄ O ₆	—	40	60
S ₅ O ₆	—	40	80
S as colloid	—	—	20

With ammonium salts in solution, the determination with alkaline hydrogen peroxide was modified by affixing to the boiling flask a condenser and a catch containing an excess of N/10 acid to absorb the ammonia, which was added to the main solution before titrating in the cold.

Several ammonium thiosulphate-polythionate solutions were prepared, the polythionate being calculated as tri- and tetrathionate; the results appear in Table I. The test for pentathionate was carried out qualitatively by the addition of ammoniacal silver nitrate solution and noting the time taken for the precipitate to form and the bulk of the precipitate. For each test equal amounts of polythionate were measured into a test tube and the same amount of nitrate solution added.

after about an hour. No sulphur had been deposited from the solutions, showing that decomposition of the polythionate had not occurred according to the equation:—

Sulphur was freely precipitated after treating solution (b) at 100° for different periods, and precipitates were immediately formed on adding the nitrate solution.

In experiment 2, a 1.2 grm.-mol. solution containing colloidal sulphur was partly converted into polythionate, which was afterwards decomposed at 100° C.

The above quantitative and qualitative tests show that the reaction between thiosulphate and sulphur dioxide proceeds primarily as:—

Free sulphur in colloidal form only is added to form tetrathionate and not pentathionate. The reaction:—

can hence only take place to a minor extent and is dependent on the amount of colloidal sulphur present in solution.

Before decomposition of the polythionate to sulphate salts (equation 5) interchange of the sulphur atoms of the tetrathionate molecule takes place.

This reaction may also take place at the same time as reaction 2, provided the period of conversion from thiosulphate to polythionate is of sufficient duration, but under ordinary conditions will not occur in the ratio as expressed by equation (1).

Under certain conditions, especially at higher temperatures, decomposition of the polythionate may set in before all sulphur dioxide has been absorbed by the thiosulphate. These reactions are complicated in nature and were investigated by Debus (*loc. cit.*). The general trend is the formation of polythionate molecules with an uneven number of sulphur atoms, which was borne out by experiments 1 and 2. These solu-

In experiment 1, sulphur dioxide was led into two portions of a 2 grm.-mol. per litre ammonium thiosulphate solution, which had been heated on the water-bath until all colloidal sulphur was precipitated. After standing for 20 hours at 12° the sulphur dioxide had been absorbed and converted into polythionate. On testing, solution (a) turned opaque after some time and a slight precipitate had formed next day. Solution (b), with more polythionate, showed somewhat more coloration, which developed into a precipitate

tions after decomposition consisted, besides the sulphate, chiefly of tri- and pentathionate molecules.

2. Reactions between ammonium polythionate and ammonia.

The velocity of this reaction was studied at various temperatures. A polythionate concentration of about 0.25 and 0.5 grm.-mol. was chosen and that of the total ammonium 1.2 grm.-mols. per litre.

The solutions were mixed cold, and after pipetting an aliquot portion, were run through

a glass spiral, which acted as a preheater, into a flask in a thermostat. From time to time 10 c.c. was withdrawn, made up to 100 c.c. and the components determined. Free ammonia was arrived at by titration with *N*/10 acid and thiosulphate with *N*/10 iodine. The polythionate concentration was ascertained after oxidation with mercuric chloride, allowing for the free ammonia determined beforehand. The difference between the total double gram.-mols. of ammonia and these three components gave the number of gram.-mols. of SO₄ in solution. All tests were corrected to the original concentration.

The velocity of the reaction is dependent on the temperature, and a rise of 10° C. increases the

rate between two and three times. Otherwise the reaction is concluded independently of the number of gram.-mols. per litre participating. The end reaction, expressed as gram.-mols. in Table 2, does not vary with the conditions of the experiment and is approximately the same at all temperatures. It was also found that excess of either ammonia or polythionate is without influence on the velocity or the end reaction. No sulphur is precipitated and the solutions remain clear until the free ammonia has been absorbed, when with polythionate present the solution turns suddenly opaque. This point marks the completion of the reaction.

For the correct interpretation of the reaction

it is necessary to refer to the graphical representation in Fig. 1. Interaction first occurs without the formation of sulphate, which is indicated by the coincidence of the $S_2O_3-SO_4$ lines, although with all determinations sulphate was found to have been formed. At this period the ratio $\text{gm.-mols. } (NH_4)_2O \text{ to } S_8O_6$ approaches 1.5:1.0. The nearest approach to this reaction was afforded by experiment 3 at 40°, when at the end of the first hour the reaction was expressed as $31(NH_4)_2O + 24S_8O_6 = 55S_2O_3 + 38O_2$. As no sulphur is precipitated all the sulphur atoms of the polythionate molecule have been readjusted to form thiosulphate. Greater consistency is shown by the curves at the latter end of the reaction, when the $(NH_4)_2O-S_8O_6$ and $S_2O_3-SO_4$ lines as pairs run parallel to one another. Equal numbers of gm.-mols. of each component have therefore taken part in the reaction.

The reaction hence proceeds between two extremes, which are expressed by the equations:—

It was not ascertained to what extent the reaction depended on the different polythionates, as the solutions were kept at a low temperature after their preparation and undue decomposition prevented. It is probable that interchange of the sulphur atoms between the polythionate molecules takes place during the reaction, so that the end reaction appears uniform unless a great excess of any one polythionate is present.

The reactions between the polythionates and potassium or sodium hydroxide form an interesting comparison, inasmuch as combination takes place with the formation of SO_3 instead of SO_4 ions. By accelerating the reaction, effected by slowly pipetting the polythionate into an excess of boiling and fairly concentrated hydroxide solution, the reactions between the individual polythionates occur, but not with sufficient exactitude for the purposes of a quantitative determination. These are:—

Note.—The reactions 4–8 have been expressed with ammonia as base; the reactions refer equally to the polythionates of sodium and potassium, as indicated by the above three reactions.

3. Reactions between ammonium polythionate, free sulphur dioxide, and ammonia at 100° C.

Contrary to expectations no immediate reaction occurred on mixing thiosulphate with an ammonia solution containing sulphur dioxide slightly in

excess of the proportion $2(NH_4)_2O \cdot OH_2 + 3SO_2$, beyond the solution assuming the characteristic yellow coloration of S_2O_3 ions. After maintaining the solution at 100° for several hours the colour still remained, indicating that little if any polythionate had been formed. The absorption of sulphur dioxide by thiosulphate is thus greatly retarded by free ammonia, and probably does not proceed at a measureable rate at ordinary temperatures. It was found, however, that the reaction proceeded at a reasonable rate on the addition of polythionate molecules.

The reaction was studied with varying proportions of polythionate and sulphur dioxide. As no method is available for the determination of free ammonia, and sulphur dioxide in the presence of polythionate and thiosulphate, solutions of ammonia containing sulphur dioxide were standardised and mixed with the polythionate to give the desired concentration of ions. About 15 c.c. of the solution was measured into a test tube, closed with a stopper and a glass tube drawn out to a fine capillary, and after heating quickly over a Bunsen burner, were suspended in a large beaker of boiling water of approximately 100°. The time taken for the completion of the reaction was indicated by the opacity produced on the decomposition of the excess polythionate. After cooling quickly and standing for an hour, 10 c.c. of the solution was analysed as described in Section 2. The results of experiments 11–20 are set out in Table 3.

The rate of reaction is primarily dependent on the ratio of polythionate to free ammonia. With solutions containing a ratio 1:4 the reaction is extremely retarded, despite sufficient sulphur dioxide present to form an excess of polythionate (see experiment 19). By increasing the ratio 2:4 and maintaining the total gm.-mols. polythionate, the absorption of the same amount of ammonia is reduced to a fraction of the former rate. With equal gm.-mols. ammonia and polythionate the time is still further reduced and varies according to the free sulphur dioxide present, which acts as an accelerator. Acceleration is also attained with increase of the thiosulphate concentration.

The number of gm.-mols. of polythionate and thiosulphate of each reaction were ascertained from the difference of the composition of the solution as calculated beforehand and found after each experiment, assuming that two-thirds of the SO_2 combined with thiosulphate to form polythionate. The sulphate formed for each gm.-mol. of ammonia is identical with that in the former experiments and is independent of the polythionate originally in solution. Free sulphur dioxide is added to form polythionate, which is not decomposed to sulphate until the solution has been rendered neutral after the absorption of ammonia.

Free ammonia has therefore been proved not only to exert a decided retarding influence on the absorption of sulphur dioxide by thiosulphate,

TABLE 3.

but also to prevent the decomposition, even at high temperatures, of the polythionate so formed. The *grm.-mols.* S_nO_6 and S_2O_4 expressed in the end reactions are therefore higher with increasing concentration of sulphur dioxide.

4. *Reaction between ammonium polythionate, free sulphur dioxide, and ammonia and ammonium sulphide at 100°.*

The above reactions suggested the possibility of modifying the Feld process, and as an alternative it is suggested that the ammonia after it has been washed from the gas, could be absorbed in a polythionate solution, which would replace the sulphuric acid universally employed. Owing to the slowness of the complete conversion of sulphur dioxide by thiosulphate solutions at ordinary temperatures, the Feld washing solution contains the minimum of polythionate necessary for the extraction of ammonia, so that this solution would not meet the requirements arising with high ammonia concentrations. Hence the substitution of part of the total polythionate by free sulphur dioxide.

To approach the conditions arising in actual practice, where the ammoniacal liquor contains ammonia in combination with carbon dioxide and hydrogen sulphide, with excess of the former, the previous experiments were modified by adding ammonium carbonate in solution to the polythionate containing free sulphur dioxide. On mixing and heating to 100°, the carbon dioxide liberated carried away much of the ammonia added, unless a large excess of sulphur dioxide were present. By gradually raising the temperature after the solutions had been mixed and allowed to stand, no ammonia was lost and the end reaction was practically identical with those of former experiments. As it was desired also to determine the factor of time, and as the formation of polythionate was less accurate by the addition of sulphur dioxide in solution owing to the presence of free sulphuric acid, the procedure of the previous experiments was reverted to.

Freshly-prepared ammonium sulphide, standardised to contain 2 *mols.* of ammonia to 1 *mol.* of sulphuretted hydrogen was first added to the polythionate solution. On mixing this with the ammonia and sulphur dioxide the temperature rose appreciably and fine sulphur was precipitated. After heating to 100° this was absorbed and the solution remained clear until decomposition of the excess polythionate occurred.

The first reaction to take place on mixing the solutions appears to be according to equation (1). Reaction between polythionate, the remaining sulphur dioxide, and ammonia would then proceed after the manner of experiments 11–20. The number of *grm.-mols.* in the second phase was accordingly arrived at after assuming the absorption of 1.5 *mols.* SO_2 by each *mol.* $(NH_4)_2S$. (See Table 4.)

In contrast to these experiments, considerably less sulphate is formed by the ammonia molecules reacting in the presence of sulphuretted hydrogen.

and the reaction is completed in a considerably shorter time. The rate of fixation of the free ammonia is not affected to the same extent by a decrease in concentration of the original polythionate, and is even accelerated with low polythionate and high sulphur dioxide content (compare experiments 23 and 26). In experiment 23, where the total polythionate concentration was about the same as in experiment 19, the absorption of equal *grm.-mols.* of ammonia per litre was completed in the short time of 8 minutes. The rate of absorption is also more favourable with increase of the total concentration.

It would appear that a line of demarcation cannot be drawn between the two separate reactions as suggested above, which are in reality more complicated and occur simultaneously.

The absorption of free ammonia by polythionate and free sulphur dioxide is thus more favourable in the presence of sulphuretted hydrogen, as the amount of polythionate in the absorbing solution can be reduced to a minimum and the period of absorption considerably shortened.

5. *Application of the reactions to the industrial process.*

The requirements for the successful recovery of sulphate of ammonia would be met by a plant of the following description (see Fig. 2). The ammonium thiosulphate solution, containing also sulphate, is partly converted into polythionate by passing through the absorber, D_1 , in the opposite direction to that of the gases containing sulphur dioxide from the furnace, O , and runs into the tank, A_1 , until nearly full, when the solution is diverted to tank, A_2 . Sufficient condensate from the still, S , is then passed into A_1 to allow an excess of polythionate after absorption of the ammonia. The solution is then pumped through the heat-interchanger, C , into the tank, B_1 , whereby the temperature is raised to approximately that of the other solution issuing from the tank, B_2 , and this latter solution is cooled for the absorption of sulphur dioxide in D_1 . After maintaining the temperature at 90°–100° until the solution becomes opaque, it is passed in the reverse order into A_1 , whilst the solution from A_2 is forced into B_2 ; these operations are then repeated alternately. Any ammonia or sulphur dioxide liberated with the carbon dioxide from the tanks is recovered in the system by passing through D_1 .

Ammoniacal liquor is fed into the still, S , through the preheater, P , which is so regulated that the water vapour carried over with the ammonia may be kept constant and the solutions maintained at any desired concentration.

Portion of the solution is withdrawn periodically and pumped over the absorber, D_2 , where treatment with more sulphur dioxide is effected. The polythionate thus formed is decomposed into sulphate by heating in tank F , and the solution freed of its sulphur before running into the lower tank, H . From here it is drawn into the vacuum-evaporator, V , evaporated, and the salt dried

in the centrifugal, Z. The sulphur recovered is burnt in the furnace, O.

Being cyclic, the process would be adaptable to continuous operation and could prove effective provided that sulphur dioxide and ammonia admitted to the system were maintained in the correct and constant proportions.

It is evident that advantages are to be obtained by the accumulation of sulphuretted hydrogen in the ammoniacal liquor undergoing recovery. Firstly, the absorption of the ammonia will be completed within a more uniform and considerably shorter period. Secondly, the sulphur will be recovered from the gas as such, as it will be precipitated on decomposing the polythionate solution. Thirdly, the formation of sulphate will be

sulphur, in combination with the washing process of W. B. Davidson,* or with a simpler method for the purification of coal gas as described by O'Neill.†

The author hopes that these suggestions will prove useful in overcoming the difficulties in the recovery of ammonia, due to shortage of sulphuric acid, although he is aware that protection of the above suggestions is fully afforded by the patent rights of the Feld process.

Summary.

- (1) Reaction between thiosulphate and sulphur dioxide takes place according to equation (2).
- (2) Other reactions taking place under certain

FIG. 2.

low and the process rendered more stable, since at no time must the concentration of thiosulphate in the absorbing solution decrease. Fourthly, subsequent purification of the gas will be rendered more economical, as a saving of space and labour is effected by relieving the work of the oxide of iron purifiers, and, fifthly, more H_2S would be absorbed from the gas, than by washing with an ammonium polythionate solution.

Other advantages are that the process for its inception would entail no extensive alterations to the plant for the general indirect method of recovery of ammonia, which has not been universally superseded by direct recovery processes using sulphuric acid. The process would also be specially suitable, as a means of utilising the

conditions, but not influencing the main reaction, take place according to equations (3) and (6).

(3) Although the reaction between polythionate and ammonia solution, as expressed by the products of the reaction, appears uniform, the reaction proceeds between too extremes, as represented by equations (7) and (8).

(4) The reactions between tri-, tetra-, and pentathionate and potassium or sodium hydroxide may take place separately according to equations (9) to (11).

(5) The velocities of these five reactions greatly increase with rise of temperature.

* J. Gas Lighting, 1913, 122, 948-958.

† 8th Intern. Congress Appl. Chemistry. See this J., 1912, 862.

(6) Sulphur dioxide is not absorbed by ammonium thiosulphate in the presence of ammonia unless polythionate is present in solution. It is then added to form polythionate, which does not decompose to sulphate at 100° , so that the amount of sulphate formed for each ammonium concentration is the same as with polythionate and ammonia.

(7) When ammonia acts upon ammonium polythionate and sulphur dioxide in the presence of sulphuretted hydrogen, that is ammonia and ammonium sulphide, less sulphate is formed than in the absence of sulphuretted hydrogen, and the velocity of the reaction is considerably greater.

(8) The Feld process of ammonia recovery could be profitably modified according to the results of the experiments and for the reasons set forth.

THE ESTIMATION OF XYLENE IN SOLVENT NAPHTHA.

BY PERCY E. SPIELMANN, PH.D., B.Sc., F.I.C.,
AND F. B. JONES, B.A. (Cantab).

The difficultly attendant on this estimation is due to the fact that xylene itself consists of three isomers of different boiling points and specific gravities, and that it exists as such in a complex mixture of cumene, trimethylbenzenes, and other substances which boil gradually up to 170° C. and over. It has been found that if the benzene, toluene, and xylene be completely removed by careful and repeated fractionation from different makes of solvent naphtha, and the fraction of the residue boiling from 143° — 170° C. be examined in a constant boiling point apparatus (such as that devised by Northall-Laurie in connection with his estimation of toluene) the constant boiling point obtained scarcely varies with the different makes.

Commercially pure xylene, fractionated and collected between 138° and 143° C., gives in the same apparatus the constant boiling point of 139.15° C. It becomes possible, therefore, from examination of known mixtures of xylene with the 143° — 170° C. residue, to construct a curve by means of which the composition of unknown similar mixtures may be found from their boiling points.

100 c.c.—or 200 c.c. if necessary, for Colman's analysis—of solvent naphtha, accurately measured, is distilled over a Young 12-pear head at the usual rate of one drop a second. The fractions up to 138° C. and from 138° C.— 170° C. (all temperatures being corrected) are collected in separate cylinders and measured.

The benzene, toluene, and xylene in the first fractions (up to 138° C.) are estimated by Colman's methods for examining toluols and solvent naphtha. The xylene in the 138° — 170° C. fraction is evaluated by taking the boiling point in the constant boiling point apparatus, and referring to the appended graph.

All possible care must be taken to get an accurate reading for the boiling point, corrections being made for barometric pressure, thermometer error, and unexposed stem, as is customary in such determinations. A steady temperature is usually attained after about 20 minutes' boiling at such a rate that the liquid condensed from the vapour, drops back from the end of the condenser at the uniform rate of one drop a second. After constancy is approximately attained, there is a slow rise in temperature on continued boiling, due, apparently, to the warming up of the unexposed stem of the thermometer, and of the end of the reflux condenser.

The accuracy of the boiling point curve may be

taken as $\pm 1\frac{1}{2}^{\circ}$, when the xylene content of the 143° — 170° C. fraction is above 50%, but owing to the divergence of boiling point of the "higher than xylenes" there may be an error of more than $\pm 2\frac{1}{2}^{\circ}$ when only small quantities of xylene are present. As, however, the average quantity of xylene in solvent naphtha is about 60%, the region of the curve showing the maximum error will not be employed in practice.

Determination of the composition of mixtures of xylene with the 143° — 170° C. residue from three makes of solvent naphtha, other than those from which the curve was constructed:—

	Taken (Xylene %).	Found (Xylene %).
1.....	11.6	14.0
2.....	29.3	28.8
3.....	66.9	63.5

For the sake of completeness, a full example is given of the examination of a sample of commercial solvent naphtha, including the corrections for unexposed stem and barometric pressure, and their applications.

The correction for unexposed stem may be calculated from the formula:

$$\text{No. of degrees to be added to observed reading} = 0.000143 (T-t) N.$$

T = observed reading.

t = temperature of external part of stem.

N = number of degrees not exposed to the vapour.

More conveniently and quickly this correction can be ascertained from a graph (Wheeler, this Journal, December 15th, 1916).

The correction for barometric pressure is given by the equation:

$$\Delta t = 0.046 (760 - p).$$

Δt is the number of degrees to be added or subtracted according to sign, and p is the corrected barometric pressure (corrected for temperature) at the time of experiment.

Example.

Volume from distillation of 100 c.c. over a 12-pear head up to 138° C. 22.1 c.c.

This 22.1 c.c. was mixed with 57.5 c.c. pure toluene and 20.4 c.c. pure benzene, and the mixture

analysed by Colman's method. The results indicated that the 22.1 c.c. contained benzene, nil; toluene, 6.2 c.c.; xylene (by difference), 15.9 c.c.

Volume from distillation of 100 c.c. over 12 pear head from 138° to 170° C.—69.7 c.c.

Boiling point of this fraction:—

Observed reading = 141.6° C.
 + thermometer error correction = 141.7° C.
 + barometric correction (for 755 mm) = 141.9° C.
 - unexposed stem correction = 143.25° C.

On reference to the curve the fraction is found to contain 67.2% xylene, corresponding to the corrected boiling point 143.25° C.

∴ total content of xylene in the original solvent naphtha = $15.9 + \frac{69.7}{100} \times 67.2 = 63\%$.

Paraffin.

An estimation of the proportion of paraffin associated with xylene may be made by the following procedure, based closely on the method of Wilson and Roberts (Gas Record, Chicago; J. Gas Lighting, 1916, 225-227; this Journal, 1916, 35, p. 681).

The quantity of the sample—100 c.c. is generally sufficient—is distilled over a Young 12-pear head at the rate of one drop a second, the portion distilling between 138°—143° C. (corrected) being collected separately. 10 to 20 c.c. of this fraction is vigorously shaken for about 40 minutes with $2\frac{1}{2}$ times the volume of weak oleum made by mixing one volume of 22% oleum with two volumes of 95% sulphuric acid.

The absorption of the aromatic hydrocarbons is carried out in a 100 c.c. flask, of which the neck is graduated into 10 c.c.s. and sub-divided into 10ths of a c.c. from the volume mark upwards. After sufficient shaking, the level of the liquid is driven up into the graduated neck by the addition of a further quantity of 95% sulphuric acid.

After standing—preferably over night—the paraffin will be found to be sharply separated.

Example.

100 c.c. of the solvent naphtha quoted above gave about 23 c.c. between 138° and 143° C. 20 c.c. of this fraction yield 2.5% of paraffin residue.

This is the quantity present in 20 c.c. of the xylene fraction, therefore, in 63 c.c. of the xylene (i.e., the quantity of xylene found in 100 c.c. of the solvent naphtha) there is $\frac{63}{20} \times 2.5 = 8\%$ of paraffin.

Therefore, this particular sample of solvent naphtha contains 5% of xylene, together with 8% of associated paraffin.

The inquisitiveness regarding the composition of the various fractions of light naphtha, which has been occasioned by the war, has given rise to much detailed work, so that now the main constituents of the whole series of fractions from benzole fore-runings to xylene can be estimated with considerable accuracy.

Industrial Notes.

REPORT OF THE ONTARIO NICKEL COMMISSION.

The Royal Ontario Nickel Commission, appointed by the Ontario Government in September, 1915, to investigate the resources, industries, and capacities in connection with nickel and its ores, has presented its Report. The Commissioners are: G. T. Holloway, Dr. W. G. Miller, and McGregor Young, K.C., with T. W. Gibson as Secretary.

The Commissioners are of the opinion that:

(1) The nickel ore deposits of Ontario are much more extensive and offer better facilities for the production of nickel at a low cost than do those of any other country. Nickel-bearing ores occur in many parts of the world, but the great extent of the deposits in this Province, their richness and uniformity in metal contents, and the success of the industry, point strongly to the conclusion that Ontario nickel has little to fear from competition.

(2) Any of the processes now in use for refining nickel could be successfully worked in Ontario, and conditions and facilities are at least as good in this Province as in any other part of Canada.

(3) In view of the fact that practically no chemicals are required, that there is a much more complete saving of the precious metals, especially platinum and palladium, and that electric power is cheap and abundant, the most satisfactory method of refining in Ontario will be the electrolytic process.

(4) The refining of nickel in Ontario will not only benefit the nickel industry, but will promote the welfare of existing branches of the chemical and metallurgical industries, and lead to the introduction of others.

(5) The methods employed at the Ontario plants of the two operating nickel companies are modern and efficient, although there are differences in both mining and smelting practice. It is the consistent policy of both companies to adopt all modern improvements in plant and treatment. Even during the present time of acute pressure, the Canadian Copper Company has materially increased its output without substantial enlargement of its plant, and the losses in smelting are less, both at Copper Cliff and the Mond plant at Coniston, than they were a year ago. These companies have each had their experimental stage, neither has asked nor received any government assistance, and both have earned the success which they have achieved.

(6) The present system of mining taxation in Ontario is just and equitable and in the public interest, and is the best system for this Province. Any question of change is rather one of rate than of principle. This important question is dealt with at some length in chapter XII.

(7) Experiments have been undertaken by the Commission in the production of nickel-copper steel direct from Sudbury ore, and also in the electrolytic refining of nickel. Certain improvements in the latter process have been made the subject of application for patents in Canada, United States, and Great Britain.

Mention is made of the erection in Ontario of two large plants for the refining of nickel. The International Nickel Company of Canada is erecting a plant at Port Colborne, having an initial output of 15,000,000 lb. of nickel per annum, provision being made for doubling or quadrupling this capacity. The plant is expected to be in operation and turning out refined nickel in the autumn of the present year. The second refinery is that of the British America Nickel Corporation,

and will probably be erected at the Murray mine, about three miles from Sudbury. The Hybinette electrolytic process will be employed. This plant will have a capacity at the beginning of 5000 tons of nickel per annum.

In regard to the refining of nickel the Orford, Mond, and electrolytic processes are described and compared, the Commissioners remarking that the respective costs of producing refined nickel from the Sudbury ores by each of the three processes mentioned, do not differ to such an extent as to give any one process a material advantage over the others in competition. The electrolytic process, which the Commissioners regard as most suited to Ontario conditions, can be operated as cheaply and efficiently in Ontario as in Norway.

The production of nickel as a by-product in electrolytic copper refining is also referred to, and attention is drawn to the precious metal contents of the Sudbury ores. Roasted matte from two of the companies showed Pt. 0.1235 and 0.988 oz.; Pd, 0.197 and 0.984 oz.; Au, 0.027 and 0.256 oz.; Ag, 1.84 and 6.15 oz., respectively.

Chapters of the Report are devoted to the history of nickel production in Canada, the world's deposits of ores, the metallurgy and uses of nickel, and many other aspects of the subject.

SULPHURIC ACID MANUFACTURE BY THE CHAMBER PROCESS.

In our Feb. 28th issue (p. 196), an account of the Fairlie analytical method of control of the chamber process was published. A recent issue of the *Chemical Trade Journal* contains an article by H. E. J. Cory on the subject, in which the author gives it as his opinion that the Fairlie method, though excellent, does not go far enough, and he proceeds to note a number of directions in which scientific control of the process is necessary.

In the first place he mentions the necessity for maintaining an adequate supply of atmospheric oxygen in the system, this being regulated in conjunction with a comparatively rich burner gas. A series of daily tests of the burner gases for SO_2 , SO_3 , and oxygen are very necessary, and often considerable fluctuations are to be found, particularly in the case of hand-worked burners, the variations being due largely to working operations from time to time. Particularly on sets working with a low chamber space, a good supply of atmospheric oxygen is essential, since otherwise the nitre will supply the deficiency.

Granted an adequate supply of inlet oxygen in the burner gas (9 to 10% when using pyrites), a rich SO_2 is also desirable, say $6\frac{1}{2}$ to $7\frac{1}{2}\%$, and at the same time a sufficiency of oxygen at the exit should be available. With a "tight" set this latter figure should not fall below 5%, and to a large extent will regulate the composition of the burner gas itself.

The percentage of total acids and oxygen in the gases leaving the Glover tower, but before entering the first chamber, is another useful test, as it demonstrates the amount of work done by this tower and is an aid to the most effective working of the Glover. Again, the functions of the Glover tower are to be constantly observed, so that one obtains perfect denitration, effective gas admixture and cooling, satisfactory concentration of acid, efficient cooling of the acid leaving the tower, and free gas passage through the tower.

The temperatures of the gases at the front and back ends of the first chamber should be noted at regular intervals, and water gauges placed at various progressive points in the system serve to show the speed of the gases.

"Drips" placed at frequent intervals on all the chambers indicate the strengths of acid being made, and should be compared with the strengths of the "bottom acids" in the chambers. The "bottom acids" should be tested frequently for strength and nitrosity, and the drips occasionally and qualitatively for nitrosity.

The acid in the chambers should be thoroughly circulated, so that all acid is drawn off at the front end of the leading chamber after traversing the length of all the chambers in the system and always moving in the opposite direction to the gases. By using connecting chutes alternately at opposite ends of the various chambers such a circulation can be easily effected, and intimate contact between acid and gases is established, fresh acid surfaces continually presenting themselves. Also, the leading chamber may be used as a "denitrating" chamber, so that all acid run off from the chambers is free from nitrous compounds. This is not essential, and often not advisable where the whole or a large part of the acid make is concentrated by the Glover tower. Any nitre contained in the "bottom acid" flowing round through this leading chamber is thus evolved, and, intermingling with fresh gases from the Glover tower, proceeds through the system again. At times acid may be again despatched to the last chamber after having worked round, in order to come forward again, thus maintaining an active acid circulation continually. With acid continually on the move, a nitre content to a reasonable extent frequently helps the working, and at the same time does not damage the lead materially, as no stagnant acid is present in the system.

The acid distribution on the tower tops requires regular attention, and constant flows, particularly on the Glover tower, should be maintained. Any shortage or excess of nitrous vitriol in the circulating acids can be remedied by adjustment of the absorber tower feeds, the Glover feed never being reduced for this purpose.

As oxygen is required in the absorber towers to ensure correct reactions, gas tests taken between the last chamber and first absorber are most useful. The SO_2 at this point should not exceed 0.1 to 0.2%, and oxygen should be 5% or more, these figures applying to sets burning pyrites. A rise in these figures does not necessarily demonstrate a deficiency of nitre in the system, but may be due to excessive draught, which is easily righted.

Tests of the gases for total acids, i.e., SO_2 and SO_3 combined, together with oxygen, may be taken occasionally at the end of each chamber, and give the operator an indication of the comparative work done by each chamber in the set.

On the absorber towers cool acid is essential, and should not exceed 90° to 100°F. , while a minimum strength of 140° Tw. is desirable. Where two absorbers or a series are working, intelligent variation and adjustment of the flows render absorption the more satisfactory.

To maintain a good "nitre circulation," the acid flowing down the Glover should be frequently measured at the inlet, the nitre contents being tested simultaneously. This enables the circulation of nitre going forward from the Glover tower to be calculated.

Nitrosity tests of the acids leaving absorber towers should be taken thrice or more daily, and the gas "smell" test is very useful. In the latter test the operator takes a sample of chamber gas into a small hand aspirator at a place not too far back in the system. A little experience enables him to judge how the chambers are working by differences in the odour of the gases, and any variation or tendency towards "souring" is checked by an extra charge of nitre at the pots.

Exit tests may be done with advantage about thrice daily (express as grains SO_2 per cubic foot of gas), and a good working figure should usually not exceed 1.5 to 2 grains. As the "burner gases" at certain periods come forward into the chambers in "flushes," the following method of applying the nitre at the pots is recommended as being most economical. A minimum amount of nitre is added each hour at the pots, and this should be accurately weighed on a scale, and at intervals this amount is raised—*i.e.*, if 10 lb. per hour is being potted, perhaps every three or four hours, 20 lb. would be added in order to counteract the gas "flushes." This is undoubtedly more economical than using a regular and heavier charge of nitre hourly, and the "smell" test is of great utility at this point. With the latter method a continuous nitre saturation is present, and this state of affairs is certainly not beneficial to the leadwork, as, on the contrary, occasional "souring" of the gases has, if anything, a good effect upon the leadwork.

A fan worked by direct-coupled motor and equipped with variable speeds should be fitted between the two absorbers, and the speed taken at regular intervals. A convenient speed for most systems is 300 to 400 revolutions per minute on the fan. A control damper fitted in the draught pipe between the last chamber and the first absorber is very suitable, and the sizes of the draught pipes should gradually diminish throughout the system. Inspection doors fitted into the chamber curtains at a height of some 3 ft. or 3 ft. 6 in. above floor level enable the operator to observe the colour and movements of the gases, and are useful when acid samples are required. These doors should preferably be at an angle of 45° to the lead curtain. The speed or draught is an important factor requiring frequent observation.

The control of the burners or furnaces is the most important part of the system: the control of the burners largely depends upon the analysis of the "burner gases," but painstaking examinations of the burners themselves are necessary to ensure good and regular chamber workings.

By adopting such means of control as described, a most economical nitre usage with a maximum make of acid should be obtainable. A maximum figure for "nitre circulation" should be decided upon for each set, as too much nitre going forward, while reducing the amount to be added at the pots (to make good chemical and mechanical losses), has a detrimental effect upon the chamber leadwork. With a reduced chamber space, however, the nitre circulation requires usually to be raised, and this undoubtedly largely contributes to the increased wear and tear. Where several sets are working together or adjacently, as in many of the larger and more modern works, these methods of control should prove very useful. Where nitric acid is used the same rules apply, though nitre may also be used for the purpose of counteracting gas "flushes" where practicable.

NEW FRENCH CHEMICAL MANUFACTURES.

According to *L'Industrie Chimique* (April, 1917), a factory has been erected at Ponthierry (Seine-et-Marne) for the manufacture of sodium bichromate. Formerly the whole of the French requirements of bichromate, about 3000 tons annually, were imported from England and Germany. Owing to the difficulties of crystallising the salt, it was at first sent out in the form of a concentrated solution, but these difficulties have been overcome, and a crystalline product is now being produced at the rate of about 500 kilos. per day. The factory

is being enlarged so that the output will be quadrupled in the near future. A works at Château-Ponsac has recently commenced the manufacture of golden antimony sulphide. Prior to the war, this substance was made on a small scale in the north of France, but the greater part of the amount required was imported from Germany and Austria. At the same works potassium permanganate is also being manufactured, the daily output being 100 kilos., soon to be increased to 500 kilos. Potassium carbonate and other potassium salts are now being produced at Choisy-le-Roi from the residues from the molasses distilleries. Formerly this industry was carried on in the north of France on a fairly extensive scale, but the works where it was in progress are in the war zone.

ALCOHOL FROM CARBIDE IN SWITZERLAND.

According to a recent issue of the *Statist*, the leading Swiss hydro-electric concerns as well as the aluminium company, the Lonza, Ltd., have now completed their researches in connection with the production of pure alcohol for industrial purposes from calcium carbide. Industrial alcohol is under Government control in Switzerland. The introduction of this new industry will be the joint work of the Federation and the Lonza, Ltd. In spite of the high prices of coal (a truck load from Germany costs 600 fr.) the Lonza will be able to sell spirit of second quality at £21 2s. per metric ton and pure industrial spirit at £22 4s. per metric ton. This is far less than the Swiss Federation pays now for imported spirit. Switzerland will thus become an exporter instead of an importer of alcohol. The installations with about 20,000 h.p. in minimum and 30,000 h.p. in maximum (summer time) will produce annually 7500 tons of alcohol minimum, and 10,000 tons maximum.

G. C.

FERRO-CONCRETE SHIPS.

The increasing use of ferro-concrete for building ships in Scandinavia has drawn attention to the results of recent work on the effects of salt water on concrete. The theory most widely held to account for the destruction of concrete is that the magnesium sulphate in sea water reacts with the free lime in concrete, and that the calcium sulphate, being of greater volume, exerts a bursting effect on the structure. This has suggested the use of cements free from excess lime, *e.g.*, puzzuolana cements, which contain excess of silicic acid, and such cements have been used for the purpose for some years.

An extensive series of tests is being carried out at the island of Sylt, in the North Sea, with concrete blocks placed on the sea shore so that at high water they are completely submerged and at low water only partly so. Two mixtures were used, *viz.*, (A) containing 65% CaO and 6–8% Al_2O_3 and Fe_2O_3 , and (C) with 61–62% CaO and 10–12% $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$. In 1:2 mixtures the blocks made of (A) were unaffected after 4 to 5 years, but the (C) mixture showed cracks after 2 to 3 years. In 1:4 mixtures the edges of blocks of (A) cement had suffered, and with poorer mixtures the blocks were much affected after 1 to 2 years.

In an exhaustive series of tests made recently in Germany, concrete mixtures of 1:3 and 1:6 were exposed to the effect of various solutions during a period of six months. Portland cement, with 63.23% of lime, was used. The following solutions were employed:—(1) Sodium chloride, up to 100 grammes per litre; (2) sodium sulphate,

up to 100 grms. per litre; (3) calcium sulphate, saturated; (4) magnesium sulphate, up to 100 grms. per litre; (5) magnesium chloride, up to 100 grms. per litre; (6) calcium chloride, up to 100 grms. per litre. The 1:6 concrete was all more or less affected, but all the 1:3 concrete tests showed that no harm had been done to the concrete, except in one case, in which the block had been kept in a closed desiccator during the hardening, and had been submerged in calcium sulphate solution. The use of too much fine sand in the mixture is undoubtedly injurious.

It is clearly evident that concrete can only be affected by sea water to the extent the water penetrates it. If the concrete is sufficiently dense, nothing but the surface is exposed to any risk, and the making of dense concrete is no longer a novelty.

Protective measures in the construction of concrete ships may be summed up as follow:—(1) The use of rich concrete; (2) the use of cement with but little free lime, gypsum, and alumina; (3) the addition of puzzuolana to fix the free lime; (4) the use of coarse sand; (5) the use of dense concrete; (6) surface treatment. Should the cement boat-building industry develop there should not be much trouble in guarding against decay if full use be made of our present knowledge.—*Engineering*.

Obituary.

JOHN H. SMITH.

Dr. J. H. Smith, an original member of this Society, died suddenly on March 20th, at the age of 57.

Born at Kircaldy, he received his scientific education at the Royal College of Science, Dublin, and later at the Zürich Polytechnikum under Lunge, taking his degree for a thesis on "The oxidation of sulphur compounds occurring in the manufacture of caustic soda" (see this Journal, 1883, 460, 525). From Zürich Dr. Smith went to Milan, where for a year he was engaged with a firm on the utilisation of tin scrap; some of the results of this work are described in this Journal, 1885, p. 312. Returning to England, he was appointed chemist to Messrs. Mawson and Swan, of Newcastle, but after some years he again went to Zürich to establish a manufactory of photographic plates and papers. About 1908 he installed a small factory in Paris for the manufacture of U'color bleach-out papers, a subject to which he devoted a large amount of attention; he found in thiosinamine and its derivatives a series of sensitisers much more powerful than anethol, which had previously been used for the purpose. His work on the subject shows the extreme difficulties encountered in the preparation of "bleach-out" papers of sufficient sensitiveness and yet yielding permanent results.

For some time prior to his death, Dr. Smith had been living in Manchester, where he had been carrying out research work at the Municipal School of Technology. The results of some of this work on phosphoric acid and the alkali phosphates are embodied in three papers which he read before the Manchester Section of this Society, on Jan. 12th last, and which were printed in the April 30th issue of this Journal.

FRANCIS SUTTON.

The death occurred at Norwich, on April 16th, at the age of 86, of Francis Sutton, the author of the widely-known work on "Volumetric Analysis."

After completing his apprenticeship in pharmacy at the age of twenty, he joined a former fellow-apprentice in business at Newcastle-on-Tyne, where he remained for three years. There he came under the influence of Dr. Glover, a physician, who advised him to take up chemistry as a profession, studied at the Durham College of Science, and duly qualified as a pharmacist. In 1851, he returned to Norwich to manage the business where he was originally apprenticed. Turning his attention increasingly to chemistry apart from pharmacy, he became Public Analyst for the County of Norfolk and other authorities. He was also consulting chemist to the local agricultural associations and, being specially interested in fertilisers, founded in 1870 a chemical manure and acid works at Runham, Great Yarmouth, of which he remained Managing Director until 1893, when he disposed of it to Messrs. Prentice Bros., Ltd. He was for many years a Member of the Council of the Pharmaceutical Society of Great Britain and one of the founders of the British Pharmaceutical Conference. In 1874, he represented British pharmacy at the International Pharmaceutical Congress at St. Petersburg, being a corresponding Member of the Imperial Pharmaceutical Society of that City and also of the Apotheker Verein of Vienna.

As a chemist he is known chiefly for his work on "Volumetric Analysis," which is accepted among chemists throughout the world as the standard work on the subject. The first edition appeared in 1862; a French translation of the fourth edition was published in Paris in 1883; and the eleventh English edition is now in preparation under the Editorship of his son, Mr. W. L. Sutton, and Mr. A. E. Johnson. He was an Original Fellow of the Institute of Chemistry, and contributed many papers to scientific journals, his earliest being two papers on the determination of phosphoric acid by means of uranium, published in the *Chemical News* in 1860.

THOMAS UTRICK WALTON.

The Sydney Section of the Society has sustained a heavy loss by the death on Feb. 1st of T. U. Walton, who had been Secretary since its inception in 1903; the success of our Australian Section was due in a very large measure to his energy and zeal.

Born at Greenock in 1852, he was educated at Greenock Academy and Glasgow University. After spending some years in Greenock sugar refineries, he went to Sydney in 1880 as Chief Chemist to the Colonial Sugar Refining Company, a position which he held until his death. He was one of the pioneers in the application of chemical control to a manufacturing business in Australia, and was responsible for the training of a very large number of chemists for the Company's works.

Since the commencement of the war he had been a member of the Chemical Section of the State Munitions Committee.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.
United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—
 Patent number, date, name of patentee, and title of invention.
French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Ferou S. Paris (3e.)
 Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Disintegrating machines. A. D. Furze and A. J. Neill, London. Eng. Pat. 104,485, Dec. 2, 1916. (Appl. No. 17,318 of 1916.)

A BOX, provided with a sliding discharge door, is fixed opposite an opening in the casing of a disintegrating machine with rotary beaters, below the outlet for the pulverised material and preferably at the point where the beaters commence their upward movement. Any unpulverisable materials entering the machine are thrown into the box and discharged from time to time.—W. H. C.

Pulverising machine. F. C. Ferry, East Cambridge, Mass. U.S. Pat. 1,217,930, Mar. 6, 1917. Date of appl. July 10, 1916.

The apparatus consists of two superposed casings of different diameters, the lower, larger casing having a perforated bottom and a perforated rim extending upwards. Agitation is effected by a reciprocating perforated disc provided with agitator blades.—W. H. C.

Sandwasher for washing fine sand. J. Southall, Worcester. Eng. Pat. 104,637, Aug. 30, 1916. (Appl. No. 12,278 of 1916.)

To enable fine sand to be washed without excessive loss by suspension in the water, the sand is fed into the top of a vertical vessel opening at the bottom into a communicating passage between similar adjacent vessels on either side. The sand falling into this communicating passage is conveyed along a horizontal conduit by a screw conveyor, into a vertical conduit, through which it is raised by a bucket elevator. The washing water is admitted into the last-mentioned vertical conduit and passes through the apparatus in the opposite direction to the sand, except that it finally overflows from the slightly lower rims of the two vessels adjacent to the sand inlet. The sand is thus fed into a quiescent body of water and is not carried away by the overflow.—W. F. F.

Furnaces. J. Sackett and S. A. Cobbett, London. Eng. Pat. 104,766, Mar. 30, 1916. (Appl. No. 4711 of 1916.)

OIL fuel is injected through the nozzles, D, into the combustion chamber, C, shown in sectional

plan, while primary air is drawn in through the pipe, E², chamber, E, and passages, E³, below the chamber, C, where it is preheated, to the nozzle, D. The walls of the chamber, E, form a bridge of less height than the combustion chamber, and the combustion gases impinge on the wall, E¹, and pass over the top of the chamber, E, to the outlet. Secondary air is drawn in through the passages, G, G¹, where it is preheated, and complete mixing is ensured by high pressure superheated steam injected through the jet, K, and directed between the inclined baffle plates, J, J¹, as shown. The combustion gases circulate as shown by the arrows.—W. F. F.

Liquids and gases: Mutual treatment of —. F. E. Coombs, Au Sable Forks, N.Y. U.S. Pat. 1,217,156, Feb. 27, 1917. Date of appl. Apr. 15, 1913.

THE gases are drawn through or over the surface of the liquid by a steam injector. The mixture of steam and gas is then cooled to condense the steam, and the gas, still under pressure, but substantially free from steam, is forced through the liquid.—W. H. C.

Power plant. R. A. Fessenden, Brant Rock, Mass. U.S. Pat. 1,217,165, Feb. 27, 1917. Date of appl. Mar. 8, 1909.

A WORKING fluid is exposed to the heat of the sun's rays in a vessel provided with a transparent cover containing an iron salt, and is heated to a point short of the boiling point at atmospheric pressure. The heated liquid is converted into vapour at a lower pressure than that of the atmosphere, and the vapour so produced is used in a suitable low-pressure engine. Part of the energy produced by the engine is used to pump water from a lower to an upper tank to be used in the condenser of the engine.—W. H. C.

Filter-bodies: Method of testing —. E. Zahm, Assignor to Zahm Manufacturing Co., Buffalo, N.Y. U.S. Pat. 1,218,151, Mar. 6, 1917. Date of appl. Oct. 21, 1912. Renewed Jan. 26, 1917.

A POROUS filter body is wetted so that the interstices are sealed by liquid. It is then subjected to gas pressure, and the pressure at which the seal is broken is determined.—W. H. C.

Pressure-filter: Centrifugal —. F. K. and E. F. Atkins, New York. U.S. Pat. 1,219,796, Mar. 20, 1917. Date of appl. Dec. 13, 1915.

A VERTICAL cylindrical casing is provided with a concentric rotating hollow shaft carrying disc-like filtering elements spaced apart, and connected to the interior of the shaft, which acts as a discharge conduit for the filtered liquid. The liquid is supplied by a vertical pipe, at the side of the casing, having perforated nozzles projecting between the filtering elements. An inner pipe may be provided, movable longitudinally in the supply pipe, and having means for discharging liquid through any desired nozzle for cleaning the outer surfaces of the adjacent filtering elements. Another vertical pipe may be provided at the side of the casing, having short nozzles which discharge liquid simultaneously on the surfaces of all the filtering discs.—W. F. F.

Filter. W. H. Waggoner, Jeanerette, La. U.S. Pat. 1,218,915, Mar. 13, 1917. Date of appl., Feb. 29, 1916.

A PERFORATED cone, 9, carrying the filtering medium, is mounted on a vertical shaft, 4, so as to rotate within the tank, 1, which is provided with a conical bottom, 3, and an outlet, 2. A support,

15, carries projecting arms, 17, pivoted at 16, the arms being provided with scrapers, 18, which rest on the conical surface and are rotated as the cone rotates.—W. F. F.

Dust particles and smoke from air and gases; Process for the separation of— W. J. Baldwin, Brooklyn, N.Y. U.S. Pat. 1,218,354, Mar. 6, 1917. Date of appl., Apr. 20, 1916.

THE gas is given a rotary motion and the washing liquid, heated to above its boiling point, is projected into it. Part of the liquid explodes into vapour and agglomerates the dust particles, and part serves to wash the agglomerated particles from the apparatus. The gas as it leaves the rotating apparatus is further washed by sprays of liquid directed against it, and leaves the apparatus by a different outlet from that by which the liquid and separated dust are discharged.—W. H. C.

Distillation; Apparatus for fractional— J. T. Davis, Alameda, Cal. Assignor to L. Levy and J. Rothschild, San Francisco, Cal. U.S. Pat. 1,218,840, Mar. 13, 1917. Date of appl., Sep. 12, 1916.

LIQUID to be distilled enters the uppermost vaporising chamber, 22, by the pipe, 19, and passes from the bottom of the chamber, by the pipes, 27, to the top of the vaporising chamber next below,

and so on. Hot gases pass upward through the series of heating chambers, 5, connected by flues, 7, provided with valves, 8, and escape pipes, 29.

Baffle-plates, 9, are provided in each heating chamber. Conical chambers, 13, of slope increasing gradually downward in the series, are interposed between the heating and vaporising chambers and supplied with steam by pipes, 17. Each vaporising chamber is connected by a pipe, 23, to a condenser, 24, for the distillate.—W. F. F.

Fluid-proofed hollow object and process for making hollow objects fluid-proof. C. M. Mapes, New York. U.S. Pat. 1,219,021, Mar. 13, 1917. Date of appl., July 1, 1916.

HOLLOW objects are rendered fluid-proof by subjecting them to the maximum pressure they will be required to withstand, and while in the stressed condition filling the voids in the walls under pressure with a molten "fluid-repellent material" which solidifies on cooling and remains permanently in the walls.—W. F. F.

Dryer. M. T. Cass, Schenectady, N.Y., Assignor to The Kellam and Shaffer Co. U.S. Pat. 1,219,981, Mar. 13, 1917. Date of appl., Mar. 31, 1916.

AN insulated chamber, mounted on wheels, is divided by horizontal longitudinal partitions into several superposed compartments. The partitions extend completely across from side to side but do not extend to the ends. The material to be dried is fed on to one end of the uppermost partition and is moved to the other end by a scraper conveyor. It falls over the end and is directed by a sloping guide on to the next shelf below, along which it is again moved by a conveyor; this guide also serves as a baffle to prevent the passage of the heating agent at this end of the shelf. The material thus travels in a zig-zag fashion to the end of the lowest shelf, from which it is discharged. Heated products of combustion from a furnace situated beneath the chamber travel in an opposite direction to the material and escape through a chimney near the feed opening.—W. H. C.

Drying [solid substances] and extracting [fluids]; Process of— D. B. Banks, Baltimore, Md., Assignor to The D. B. Banks Co. U.S. Pat. 1,219,406, Mar. 13, 1917. Date of appl., May 20, 1916.

FLUIDS, substances contained in solution or suspension in fluids, or fusible substances, are separated from cellular, fibrous, or porous substances by placing the material adjacent to a regulable heater in a casing containing a saturated gas under pressure. The whole is heated to the boiling point of the contained fluids, etc., at that pressure, and the temperature and pressure of the gas are then reduced while heat is supplied to the cellular or like substance to maintain it above the boiling point of the contained fluid at the reduced pressure, the fluid being thus removed by internal evaporation, into the surrounding medium. The substance is then subjected to the action of heat in a non-saturated gaseous medium.—W. F. F.

Decolorising materials; Method of making— R. M. Catlin, Franklin Furnace, N.J. U.S. Pat. 1,219,438, Mar. 20, 1917. Date of appl., Apr. 25, 1916.

A MIXTURE of silica and a carbonaceous material obtained from an industrial carbonising process, e.g., the residue of shale distillation, is treated with dilute hydrofluoric acid. The solid residue is separated and possesses decolorising properties.—W. F. F.

Mixing-machine. H. J. Ihaigh, Stapleton, N.Y. U.S. Pat. 1,219,730, Mar. 20, 1917. Date of appl., July 7, 1914.

A MIXING bowl is supported on a vertical standard which also supports a vertical shaft carrying the beater mechanism and a friction disc. The beater mechanism may be driven at a variable speed by a

number of friction rollers spring-pressed on the surface of the disc and capable of being adjusted simultaneously by a feed screw to any desired radius of the friction disc. The friction rollers are driven by suitable gearing.—W. F. F.

Atomiser for fluids. J. Patten, Assignor to Davison Chemical Co., Baltimore, Md. U.S. Pat. 1,219,394, Mar. 20, 1917. Date of appl. Apr. 23, 1914.

THE atomiser is mounted in the cover of a tank so as to atomise liquid within the tank. Liquid is supplied tangentially to a cylindrical chamber depending from a liquid seal in the cover of the tank, and terminating at its lower end in a frustum of an inverted cone. A concentric vertical shaft rotating at a variable speed carries a disc at its lower end almost closing the outlet of the cone, so that an annular rotating stream of liquid is delivered to the disc and sprayed from it by centrifugal force.—W. F. F.

Pulverising apparatus. J. Crites, Assignor to Raymond Bros. Impact-Pulverizer Co., Chicago, Ill. U.S. Pat. 1,221,111, Apr. 3, 1917. Date of appl. July 3, 1916.

SEE Eng. Pat. 103,963 of 1916; this J., 1917, 376.

Method of fixing the walls of lead chambers. Ger. Pat. 295,911. See VII.

Process for carrying out chemical reactions. U.S. Pat. 1,217,812. See VII.

II A.—FUEL; GAS; MINERAL OILS AND WAXES.

Coke; By-product—and coking operations. C. J. Ramsburg and F. W. Sperr, jun. J. Franklin Inst., 1917, 183, 391—431.

THE recent development in the building of by-product ovens in the United States and Canada has been remarkable and it is estimated that 9900 ovens will be in operation by Jan., 1918. The development is not altogether due to inflated war prices of by-products but to financial conditions favouring large investments. In addition to economic advantages from the recovery of by-products, attention is drawn to the conservation of the coal supply brought about by the introduction of modern methods. As far as fuel values are concerned, from a total of 1.4 to 1.5 tons of coal required to make 1 ton of coke, the by-products lost in the beehive coking process have a heat value of 625 lb. of coal, whilst an additional 200 lb. is wasted by combustion of a portion of the charge. The advantages of silica material in the erection of coke ovens are stated thus:—The conductivity at high temperatures is superior to that of fireclay material; the softening temperature is higher; the action under heat may be more accurately calculated owing to constant composition; the expansion and contraction between 2000° and 2600° F. (1090° and 1430° C.) is negligible. The use of silica material has brought about a shortening of the coking period and a more extensive use of coals richer in volatile matter, with increased yields of by-products. The authors give the effect of variations in the dimensions of a coke oven, a reduction in width giving the following advantages:—less sponge in the coke; better coke from the same coal; good coke from mixtures with a higher content of volatile matter; higher yields of tar, ammonia, and benzol; lower temperatures for the same coking velocity. In referring to benzol the authors emphasise the value of this product as a motor fuel, either alone or mixed with alcohol or gasoline. A brief account of the accepted theory of the coking process is given. The process is con-

ceived as involving the formation of a fused zone and the gradual advance of this zone towards the centre of the oven, the evolved gases and vapours depositing part of their carbon in the vesicular mass left as the zone progresses. The actual thickness of this zone is probably not over half an inch, the drop of temperature across it is very great, and the interior of the oven remains comparatively cool for a considerable part of the coking process. The average rate of advance of the zone towards the centre, with ovens 18 inches wide and a wall temperature of 1000° C., is about one-half inch per hour, the initial rate being more rapid but decreasing as the centre of the oven is approached. Coke adjacent to the wall is distinguished by its cauliflower-like appearance and dense layers of deposited carbon. Towards the centre of the oven the coke is more open and occasionally spongy. As a rule coke from coals with over 30% volatile matter is of a "fingery" type, but by careful regulation of the heat treatment, firm, "blocky" coke may be produced from such coals. For any accurate comparison of cell structure the authors prefer to make longitudinal sections with a thin emery wheel, thus eliminating the danger of confusing sections made at different distances from the oven wall. These sections are compared with standards cut from blocks of typically different coals. Numerous illustrations of standards and sections are given. The authors quote the verdicts of various observers on the exact function of coke in the most efficient and economical reduction of iron ore. As furnace conditions are better understood the range of quality of the coke used may be extended, but the importance of uniformity for any particular furnace cannot be too strongly emphasised. For each kind of coke there is evidently some limiting size for efficient service, i.e., just large enough to offer a minimum surface of attack for carbon dioxide and small enough to ensure complete combustion in a minimum of time at the tuyères. Harder grades of coke should be used in smaller sizes, coke of open cell structure requiring less attention in this respect.—J. E. C.

Dusts; Inflammability of carbonaceous—in atmospheres of low oxygen content. H. H. Browne and J. K. Clement. J. Ind. Eng. Chem., 1917, 9, 317—319.

HARGER (this J., 1912, 413) has recommended a low oxygen content (17.5%) in the atmosphere of mines as a preventive of dust explosions and experiments made by the authors show that an explosion of flour or similar dust cannot be initiated in a gas mixture containing less than 12% of oxygen. In the case of flour mills where the dust could be confined in enclosed machines, the gases might be introduced into the latter; under normal conditions the gases contain nitrogen, 79, oxygen, 11, and other gases, 10%, and there would be no necessity to remove the carbon dioxide as would have to be done in a mine where men were working.—W. P. S.

Gas purification oxides. A. H. Scott. New England Assoc. Gas Eng. Gas J., 1917, 138, 101.

THE author discusses the sources and methods of production of some of the better known forms of gas purification oxides, natural or manufactured, and their sulphur absorption properties. The value of bog ores after drying, screening, and grinding is influenced by the physical condition. They are easily mixed and are comparatively free from the defect of overheating in use. Manufactured oxides are mainly by-products from metallurgical operations, residues left after extraction of alumina from bauxite furnishing a considerable portion. A high-grade oxide is produced

in the manufacture of aniline, whilst the sediment from the water of certain coal mines yields a very efficient natural oxide. Metallic paint oxide has given good results. In absorption tests under similar conditions (four foulings to each test) the percentage of sulphur taken up was as follows:—Residue from aniline manufacture, 62; sediment from mine water, 61; Pennsylvania bog ore, 61; ground pyrites cinder, 53; hematite ore, 49; hydrated iron ore, 46; residue from American bauxite, 35; residue from French bauxite, 42; residue from English bauxite, 15; Cuban bog ore, 31; "metallic paint," 49.—J. E. C.

[*Lubricating*] oil; *Resistance of*—*to emulsification*. W. H. Herschel. Techn. Paper No. 86, Bureau of Standards, Dept. of Commerce, U.S.A. Feb. 17, 1917, 1—37.

THE term "demulsibility" (see Philip, this J., 1915, 697) is defined as the maximum rate at which an oil separates from an emulsion in c.c. per hour, and it is used as a measure of the resistance of the oil to emulsification. Any method of determining it must be empirical, and the following method is therefore suggested as embodying conditions which can be readily reproduced:—20 c.c. of the oil and 40 c.c. of distilled water are placed in a 100 c.c. cylinder having an internal diameter of 26 mm., and are heated to 55° C. in a water bath. They are then stirred for 5 mins. by means of a paddle (89 by 20 by 1.5 mm.) rotating at a speed of 1500 revolutions per min. The cylinder is allowed to stand for not more than 1 hour at 55° C., and from each of the readings, taken at intervals, of the volume of oil which separates, the average rate of settling between the time of stopping the paddle and the time of observation is calculated. A perfect non-emulsifying oil would show a rate of settling of 1200 c.c. per hour, the first reading being taken one min. after stopping the paddle. Care must be taken that an average sample of the oil is used for the test, and that if received in a glass bottle the oil is not exposed to sunlight. In the case of certain oils, notably marine engine oils, part of the water may not enter the emulsion, and it may then be necessary to reduce the speed of the paddle to 1000 r.p.m., or to increase the speed, or prolong the time of stirring. A low demulsibility is invariably found when the oil has a high acidity, but the reverse does not always hold good. A similar relationship is found between the percentage of ash and the demulsibility, but the relationship between the carbonisation properties and the demulsibility is less pronounced. With regard to steam-cylinder oils the conclusion is drawn that those showing strong emulsibility are undesirable, since as a rule they will contain soap, and will show too great a decrease in viscosity between the temperature at which they are tested and that prevailing within the cylinders. Transformer oils usually have a demulsibility of 1200, and a high demulsibility is thus a proof of great purity. It has also been found in practice that oils showing high demulsibility can be used for a longer time before becoming useless from the formation of deposits. The General Supply Committee has specified in some of its contracts for U.S. Government departments that turbine and spindle oils shall have a demulsibility of 300. This is approximately the value given by a mixture of 1 vol. of equal parts of kerosene oil and olive oil with 2 vols. of water. On the other hand, a demulsibility of zero is to be expected in the case of oils, such as marine engine oils, where an emulsifying oil is required. Since oils become acid and emulsify more readily with use, the demulsibility decreases, but as a general rule, oils which have low demulsibility when new do not show so rapid a decrease as those of higher demulsibility. In the

case of five new turbine oils the demulsibility ranged from 192 to 1200, whilst 13 oils which had been in use for 1 to 36 months gave values of 3 to 98. It is suggested that a demulsibility value might be found for any particular turbine beyond which it would be unsafe to go. Determination of the acidity would give the same information but is less sensitive than the demulsibility test.—C. A. M.

Analysis of light oils [for benzene, toluene, and xylene]. Egloff. See 111.

PATENTS.

Coke oven heating flues; Construction of—R. Fabry, Sheffield. Eng. Pat. 105,017, Dec. 19, 1916. (Appl. No. 18,169 of 1916.)

THE heating flues, and air-, gas-, and waste-heat-ports of a coke oven are so arranged that a large flow of products of combustion constantly dilutes the incoming gas and air. The mixture circulates through the heating flues at a much greater rate than that determined by the individual consumption of air and gas of each heating flue, with the object of maintaining more uniform temperatures throughout the length of the heating flues.—J. E. C.

Ammonium chloride; Recovery of—in the manufacture of gas or coke. E. Myers, and The Shelton Iron, Steel, and Coal Co., Stoke, Eng. Pat. 104,942, Mar. 31, 1916. (Appl. No. 4798 of 1916.)

AMMONIUM chloride is recovered in the usual manner by spraying the gas with water at a minimum temperature of 80° C. and at about 40 lb. pressure. The solution formed may be decolorised by agitating when at boiling point in the presence of carbon, or it may be first evaporated, the resulting dried salt mixed with 2% by weight of nitro-hydrochloric acid (two parts HCl to one of HNO₃), and the whole dissolved, the resulting solution being decolorised as described, then neutralised with ammonia, and evaporated to the required strength for crystallising.—J. E. C.

Gas from liquid hydrocarbons; Apparatus for and process of making—W. C. Dayton, Buffalo, N.Y., U.S.A. Eng. Pat. 104,822, Feb. 18, 1916. (Appl. No. 10,889 of 1916.)

IN a gas producer for making a fixed combustible gas by the reaction of a mixture of liquid hydrocarbon or other combustible and air or other combustion-supporting gas, of the type in which the mixture is introduced into a heated "converter" having tortuous passages formed by radial baffles, means are provided for preheating the hydrocarbon and air or the like. The pipe conveying the mixture into the "converter" is placed within the delivery pipe for the heated gaseous product. To prevent cracking of the converter due to expansion strains, it is made in the form of a flattened ellipse in cross-section instead of rectangular, and the radial passage conveying the mixture to the centre is cast integral with the baffle-plates, while the inlet pipe is connected to this passage by a shallow taper thread.

—W. F. F.

Hydrocarbons; Recovering—from absorbing oils. W. J. Mellersh-Jackson, London. From H. Koppers Co., Pittsburgh, Pa., U.S.A. Eng. Pat. 104,890, Feb. 28, 1916. (Appl. No. 2980 of 1916.)

IN an apparatus for the continuous distillation of hydrocarbons from an absorbing oil, the oil is preheated in heat-exchangers, first by benzol vapours, secondly by hot residual oil, and thirdly by live steam. The vapours from the steam superheater are conducted to the upper portion of the main still, the oil being admitted

to the same still at a lower level. The various heat-exchangers are horizontally disposed and adapted for easy access for repairs, spare units being then utilised.—J. E. C.

Mineral oils and the like: Process and apparatus for continuously distilling — C. H. Bornmann, Essen, Germany. U.S. Pat. 1,220,067, Mar. 20, 1917. Date of appl. July 29, 1912.

MINERAL oils having a boiling point above 100° C. are preheated and dehydrated, and continuously distilled in a main column by contact at first with superheated steam, and the vapour is passed into a cooler to condense the lighter oil vapours. A portion of the steam and oil vapour from the cooler is superheated and returned to the main column for distilling the oil and feeding the column. The separated oils boiling below 100° C. are re-distilled in another column by the remainder of the steam and oil vapour from the cooler, and the distillate is drawn off for separation of the lighter constituents.—W. F. F.

Hydrocarbon oils: Apparatus for dehydrating — E. I. Dyer, Oakland, Cal. U.S. Pat. 1,220,504, Mar. 27, 1917. Date of appl. Mar. 5, 1913.

HYDROCARBON oils are treated in a series of closed vessels each provided with a system of heat-circulating tubes and with vertical longitudinal baffles arranged to form a tortuous path for the oil. Heat from an outside source is supplied to the tubes of one vessel, the vapours from this vessel passing through the heating tubes of an adjoining vessel.—J. E. C.

Hydrocarbons: Process and apparatus for obtaining from gases. G. Linderborg and W. B. Scott, Los Angeles, Cal. U.S. Pat. 1,220,651, Mar. 27, 1917. Date of appl. Jan. 15, 1916.

NATURAL gas containing gasoline or similar hydrocarbons of low boiling point is passed, along with an emulsion of water and a hydrocarbon of high boiling point, through a body of filamentary material presenting sharp points. The absorbed hydrocarbon is recovered by heating the emulsion.—J. E. C.

Continuous stills for coal tar, mineral oils, and similar products. Eng. Pat. 104,636. See III.

Retort furnace for production of hydrogen from iron and steam. Ger. Pat. 294,911. See VII.

Apparatus for indicating the composition of gases. U.S. Pat. 1,220,637. See XXIII.

A polarisation flicker photometer and some data of theoretical bearing obtained with it. Ives. See XXIII.

PATENTS.

Electric conductors suitable for sealing into vitreous material. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 101,758, Mar. 25, 1916. (Appl. No. 4153 of 1916.)

A LEADING-IN conductor for sealing into electric lamps and the like is composed of an outer shell of copper, brass, platinum, or an alloy of nickel and iron, and an inner wire of brass, copper, or brass coated with copper, the intermediate space being filled with a layer of carbon or graphite,

or other refractory material such as silica, manganese dioxide, calcium oxide, chromium oxide, powdered cast iron or steel, plaster of Paris, or china clay. The outer shell is hermetically sealed into the glass and the ends are welded to ordinary wires or otherwise hermetically sealed as by soldering. The leading-in conductor may comprise a composite wire knotted to another composite wire, or to a solid wire, the knot being embedded and sealed in the glass. The composite wire may be in the form of a bight embedded in the glass with both ends on one side, the intermediate part being connected to a conductor on the other side.—W. F. F.

Insulator: Electric — [for lamp sockets]. N. Marshall, West Newton, Mass. U.S. Pat. 1,217,873, Feb. 27, 1917. Date of appl. Jun. 20, 1916.

AN insulating lining for lamp sockets is formed from a dielectric heat-resisting carrier, in the form of an asbestos tube, impregnated with decomposition and reaction products of an emulsion, formed from a mixture of 30 to 70% of sodium silicate and 70 to 30% of linseed oil, and baked at a high temperature so as to polymerise and oxidise the oil. The insulator varies in colour from brown to black, in accordance with the higher degree of heating employed in baking, the black material being more brittle than the brown.—B. N.

Method of making decolorising materials. U.S. Pat. 1,219,438. See I.

Preserving gas. U.S. Pat. 1,219,527. See XIX.B.

III.—TAR AND TAR PRODUCTS.

Light oils: Analysis of — [for benzene, toluene, and xylene]. G. Egloff. Met. and Chem. Eng., 1917. 16. 259–263.

Distillation apparatus. The still consists of a copper flask of 4000 c.c. capacity, provided with a fractionating column, 8 ft. high, and a condenser 24 in. long. The column (see fig.) is made up of six 12 in. and one 18 in. lengths of $\frac{3}{4}$ in. and one 6 in. length of $1\frac{1}{2}$ in. iron pipe, connected by suitable unions; it has a reflux tube ($\frac{1}{4}$ in. diam.) which extends through the lowest section of the column to within 1 in. of the bottom of the flask when the latter is screwed into position. The reflux tube communicates with the main column at intervals, and the different sections of the column are separated by diaphragms of 30-mesh iron wire gauze, each of which supports an 8 in. column of glass rods 2 in. long and $\frac{1}{4}$ in. diam. The head of the column has an opening at the top for a thermometer and at the side a $\frac{3}{4}$ in. exit pipe connected with the condenser by a $\frac{1}{2}$ in. metal tube. The heating burners below the flask are surrounded by an asbestos draught screen; and when employed in draughty situations the whole column is set in a box provided with a hinged door. In testing the apparatus, 2000 c.c. portions of known mixtures of highly purified benzene, toluene, and xylene were distilled at the rate of 2 drops per sec., the rate being checked by means of a metronome and stopwatch. The mixtures contained 2–80, 3–90, and 6–58% of the respective hydrocarbons, and in every case the result obtained by a single distillation was in close agreement with the theoretical, the loss being very small. In the case of various commercial oils (e.g., Pintsch hydrocarbon oil) a much better separation of benzene, toluene, and xylene was effected by a

single distillation in this apparatus than by three successive fractionations with a standard Hempel column. *Method of analysis.* 2000 c.c. of the oil, contained in a vessel provided with a cooling coil and stirring apparatus, is agitated for about 80 mins. with 200 c.c. of 95% sulphuric acid (added at the rate of 1 drop per sec., or about 3.75 c.c. per min.), and the mixture allowed to stand for 30 mins.; the acid sludge is then discharged and the remaining oil, now free from olefines, agitated for 15 mins. with a 6% solution of caustic soda and allowed to stand for 30 mins. After separation from the alkali sludge, the oil is placed in a copper container of 4000 c.c. capacity and distilled with live steam until the temperature reaches 180° C. The oil is then separated from the distillate and, after thorough drying with calcium chloride, distilled in the apparatus described, the fractions boiling up to 95°, between 95° and 125°, and between 125° and 165° C., being collected, measured, and recorded as pure benzene, toluene, and solvent naphtha, unless the specific gravities (as determined at 15.5° C. by means of a Westphal balance) fall below 0.880, 0.871, and 0.870, respectively, when the presence of paraffins is indicated. In the latter case the proportion of paraffins present is calculated on the basis of the wide difference in specific gravity between paraffin and aromatic hydrocarbons distilling over the same range of temperature, or is determined by agitating 10 c.c. of the fraction with 25 c.c. of a mixture of 2 parts of ordinary (sp. gr. 1.84) and 1 part of fuming (20% oleum) sulphuric acid in a stoppered graduated cylinder, allowing the mixture to settle, and reading off the volume of undissolved oil. Specifications for benzene and toluene for use in the manufacture of phenol, picric acid, and trinitrotoluene are also given.—W. E. F. P.

Benzene; Thermal decomposition of — J. E. Zanetti and G. Egloff. *J. Ind. Eng. Chem.* 1917, 9, 350–356.

THE decomposition of benzene at 600° to 800° C. and ordinary pressure in an electrically heated iron tube furnace takes place in accordance with the following reactions:—

Below 750° C. the reaction velocity of the diphenyl formation is greater than that of the formation of carbon and hydrogen; above this temperature, the velocity of the carbon-hydrogen reaction becomes very great and the benzene is decomposed before other condensation products can be formed. The formation of diphenyl begins as low as 500° C. Acetylene and naphthalene are not formed during the reaction. Iron and nickel gauze favour the decomposition to carbon and hydrogen; the action of copper gauze is not marked except above 750° C., when the formation of carbon is accelerated. (See also McKee, this J., 1904, 403; Rittman, Byron, and Egloff, *ibid.*, 1916, 105.)—W. P. S.

Coal tar, mineral oils, and similar products: Continuous stills for — H. Moore and C. Day, Stockport. Eng. Pat. 104,636, Aug. 29, 1916. (Appl. No. 12,188 of 1916.)

A PLANT for the continuous distillation of coal tar, mineral oils, and the like consists of two or more stills arranged so that the vapours of the distillate from one still are conducted by a coil through the body of the tar or the like in the adjacent still without actual contact. The vapours pass through the series of stills in the opposite direction to the tar or the like. Means are provided for collecting the vapours of the distillate separately from each still, after having withdrawn heat from them by passing through the coil in the previous still, and the dimensions of the stills are such that the ratio between the area of the upper tar surface, which is free for frothing, to the volume of tar employed is greater in the stills of lower temperature and less in the stills of higher temperature.—F. W. A.

Picric acid and other nitrophenols from certain gums or gum-resins: Manufacture of — H. C. Miller, London, and H. A. Irlam, Mill Hill, Middlesex. Eng. Pat. 104,352, Feb. 2, 1916. (Appl. No. 1588 of 1916.)

PURIFIED gums or gum-resins, alone or dissolved in concentrated acetic acid, are treated below 40° C. with nitric acid, any unconverted gum or gum-resin is removed, and the solution of picric acid or other nitrophenol is boiled and crystallised.

—F. W. A.

Nitro-compounds: Making — C. Ellis and A. A. Wells, Montclair, N.J., Assignors to Ellis-Foster Co. U.S. Pat. 1,220,078, Mar. 20, 1917. Date of appl., May 31, 1916.

CHLOROBENZENE is nitrated by heating with sodium nitrate and sulphuric acid (66° B.; sp. gr. 1.84) to a temperature at which the nitration progresses regularly without the evolution of large quantities of oxides of nitrogen.—F. W. A.

Pitch or like material; Method of disintegrating and lading hard — C. Still, Recklinghausen, Germany. U.S. Pat. 1,221,211, Apr. 3, 1917. Date of appl., Sept. 22, 1915.

IV.—COLOURING MATTERS AND DYES.

Pyrene colours. A. E. Everest, J. Soc. Dyers and Col., 1917, 33, 78—86.

IN a review of the chemistry of the natural and synthetic pyrene colours, the researches of Ohmann and Pauchard, A. G. Perkin, Kostanecki and Tamber, Watson, and the author are outlined. The synthetic colours are divided into two series: diphenylmethane, or xanthene, derivatives, and triphenylmethane, or phenylxanthene, derivatives; they differ somewhat, however, from the triphenylmethane series in that they are less easily decolorised by reduction, and when decolorised their leuco-compounds are more easily oxidised by air. In this respect they behave rather more like the *ortho*- than the *para*-quinonoid colours; the violet and blue members of this class, e.g., Fast Acid Blue, particularly show this resemblance to *ortho*-quinonoid substances.—F. W. A.

[*Methylene Violet and Methylene Azure.*] *Manufacture of Methylene Blue derivatives for microscopy.* L. Tribondeau and J. Dubreuil. Comptes rend., 1917, 164, 551—553.

THE action of alkalis on Methylene Blue yields products valuable in microscopy, e.g., silver oxide yields the blue of Borrel, potassium carbonate produces the Polychrome Blue of Unna, sodium borate gives the blue of Manson, etc. Methylene Violet and Methylene Azure are prepared as follows: 5–10% of ammonia solution is added to a 1% solution of pure medicinal Methylene Blue, the liquid is heated on a boiling water-bath and filtered hot. Evaporation of the filtrate to dryness at 37–40° C. gives practically pure Methylene Violet. The residue is exposed to air in an ice-chamber for at least 24 hrs. until it has become blue-black, when it is dissolved in distilled water, filtered, and the filtrate evaporated to give Methylene Azure. Three staining solutions are prepared from the two products: (1) a 1% solution of Methylene Azure in distilled water; (2) the Polychrome Blue by mixing 1% solutions of the two products, e.g., 1 part of the azure solution to 3 parts of the violet solution; and (3) an alcohol-glycerin (3:1) solution of Methylene Azure and Eosine ("azéo"), similar to the mixture of Giemsa. Details for their use in staining are given.—F. W. A.

PATENTS.

[*Sulphur*] *colouring matter or dyes: Treatment of certain gums or gum-resins for the manufacture therefrom of —.* H. C. Miller, London, and H. A. Islam, Mill Hill, Middlesex, Eng. Pat. 191,353, Feb. 2, 1916. (Appl. No. 1589 of 1916.)

GUMS or gum-resins produced from plants of the *Xanthorrhoea* genus, commonly known as grass-tree, acaroid, botany-bay, and black-boy gums, purified or otherwise, are treated with sulphuric acid, or with an alkali and sulphur and or a sulphur compound, e.g., sodium sulphide: the former yields brown dyes for leather, wood, wool, and the like; the latter gives products yielding bronze, brown, grey, or black shades. (Reference

is directed, in pursuance of Sect. 7, Sub-sect. 1, of the Patents and Designs Act, 1907, to Eng. Pat. 1189 of 1873.)—F. W. A.

Triarylmethane-azo dyestuffs and metal compounds thereof: Manufacture of leuco — and application of the dyestuffs and compounds in dyeing. O. Imray, London. From Soc. Chem. Ind. in Basle, Switzerland. Eng. Pat. 191,743, Mar. 17, 1916. (Appl. No. 3988 of 1916.)

BY coupling the diazo-compound of a leuco-triarylmethane derivative containing in the aryl residue a hydroxyl group in *ortho* position to an amino group with one of the usual components, leuco-triarylmethane azo dyestuffs are obtained. The new dyestuffs have pronounced mordant dyeing properties, and give fast dyeings on animal fibres by the usual processes for mordant and after-chrome dyestuffs, and may be converted into copper or other metal compounds which give dyeings on animal fibres fast to milling, potting, and light.—F. W. A.

Sulphonating coal-tar dyes. E. D. Kendall, Elizabeth, N.J., Assignor to L. T. and M. V. Haggin, A. McCulloch, and H. E. Moller, exors. of J. B. Haggin. U.S. Pat. 1,217,462, Feb. 27, 1917. Date of appl., July 13, 1916.

SODIUM hydrogen sulphate is converted into the disulphate which is "persulphated" with one chemical equivalent of monohydrated sulphuric acid, and the pulverised and dehydrated coal-tar dye to be sulphonated is added to the fused mass; after thorough admixture until sulphonation of the dye is effected, the mass is dissolved in water, the excess of sulphuric acid is removed with an equivalent amount of calcium hydroxide, and the filtrate is evaporated to dryness.—F. W. A.

Chlorinated products of xylene, aldehydobenzoic acids, and [triphenylmethane] dyestuffs therefrom: Manufacture of —. J. Schmidlin and M. Fischer, Frankfurt, Germany. U.S. Pat. 1,219,166, Mar. 13, 1917. Date of appl., May 16, 1916.

XYLENES chlorinated in the nucleus are chlorinated at elevated temperatures (100°–130° C.), whilst exposed to light, until four or five more chlorine atoms have been introduced in the side chains; the products are converted by means of concentrated sulphuric acid into chlorinated dialdehydes or aldehyde-carboxylic acids which are condensed with *o*-cresotic acid, and the resulting leuco-compound is oxidised with sodium nitrite in concentrated sulphuric acid solution. The triphenylmethane dyestuffs from chlorinated aldehydobenzoic acids and *o*-cresotic acid dye wool brown-red from an acid bath, yielding after chroming bright, violet-blue dyeings of very good fastness to washing and to milling.—F. W. A.

Mercerising yarn: Machines for —. B. E. D. Kilburn, London. From Sulzer Frères Soc. Anon., Winterthur, Switzerland. Eng. Pat. 105,044, July 5, 1916. (Appl. No. 16,627 of 1916.)

IN a machine for mercerising yarn in the form of skeins or hanks, the lye tank and the trough for the neutralising liquor are mounted on shafts so that they can be swung alternately into and out of their operative position below the horizontally arranged yarn hanks. The lye tank has an outlet provided with an overflow opening into a channel, into which it discharges its contents on being turned.—F. W. A.

Dyeing, bleaching and the like of textile fibres or goods: Machines for —. H. J. Moysey, Gateshead, and H. Johnson, Leicester. Eng. Pat. 104,718, Mar. 11, 1916. (Appl. No. 3647 of 1916.)

A CONTAINER, 1, in an outer rotary pan, 2, keyed to a hollow shaft, 3, provided with slots, 4, to admit treating fluid, consists of an annular cage having a perforated central sleeve, 1a, surrounding the slots, 4, and a perforated outer cylindrical wall, 1b. The wall of 2 diverges upwards and terminates in a flared mouth opening into an annular collecting trough, 5, which has an outlet, 7, connected by a cock, 8, to either a waste pipe, 9, or a return pipe, 10, the latter being connected to

a supply tank, 11, and by means of a cock, 12, either to the hollow shaft, 3, or main waste pipe, 13. The connection, 15, may be connected to an exhausting apparatus or air compressor. On rotating 2, the liquor rises in the vat and is discharged into 5.—F. W. A.

Hook dyeing and finishing machines. F. F. Larivei, Bradford. In part from P. Fincato, Milan, Italy. Eng. Pat. 104,698, Feb. 8, 1916. (Appl. No. 1845 of 1916.)

A MACHINE for dyeing or similarly treating hanks of textile fibre contains a number of stub shafts driven from a main driving shaft through automatically reversing gearing, and having sockets to receive detachable sticks of non-circular cross-section, which support the hanks. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat., 1968 of 1868, 1810 of 1870, and 7969 of 1903; this J., 1903, 1345.)—F. W. A.

Manufacture of leuco-triethylmethane-azo-dyestuffs and metal compounds thereof, and application of the dyestuffs and compounds in dyeing. Eng. Pat. 104,743. See IV.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid: Concentration of —. E. H. Armstrong. *J. Ind. Eng. Chem.*, 1917, 9, 386—388.

IN the tower method of concentrating sulphuric acid to 93 to 97%, quartz is used as the packing material and an oil flame for the heat. In practice it is usually necessary to discontinue the operation after a week to 10 days' working, and to wash the tower out. This has been found to be caused by the acid disintegrating the quartz, as much as 50% being removed in some cases, so that the tower became so open that it would not concentrate the acid beyond 63° B. (sp. gr. 1.775). This may be remedied by opening the top of the tower, and introducing small pieces of broken quartz through a cast-iron drain pipe serving as a funnel. In the author's experience a tower thus received as much fresh quartz during a period of several months as was used for the original charge. A tower working well will usually show a temperature of about 1200 to 1400° F. (650—760° C.) for the gas entering and about 280° to 290° F. (138—143° C.) with about $\frac{5}{8}$ in. suction in the outlet flue at the top. When it is not working well an increase in the temperature of the gas entering the tower and in the suction pressure in the flue will be observed, whilst there will be a decrease in the temperature of the gas leaving the tower. When this temperature falls to about 250° F. (121° C.) very little acid of 66° B. (sp. gr. 1.84) is being made. To remedy this condition the process should be interrupted and weak acid run down the tower until the packing becomes fairly cool, after which it is thoroughly washed with water for at least 12 hours. On restarting work the temperature of the entering gas will be about 200° F. (about 110° C.) lower and that of the gas leaving the tower about 40° to 50° F. (22—28° C.) higher than before, whilst the suction pressure in the flue will only show about one-half to $\frac{5}{8}$ in. A strong suction must be obtained by means of steam jets or a fan, to prevent condensation of the vapours and distillates within the tower. On the other hand when the tower becomes too open, the gases will leave the tower too hot (350° to 360° F., 177—182° C.), and the suction pressure in the flue will fall almost to nothing.

whilst the temperature of the entering gas will decrease by 200° to 300° F. (110°—167° C.). This condition is remedied by the introduction of quartz as described. In one case difficulty was experienced owing to the brick lining between the packing and the lead having become open. This was remedied by cementing the bricks with acid-proof cement (sodium silicate and "silax"). With regard to the losses of acid it is estimated that under normal conditions when the tower is being fed with 60,000 lb. of acid of 60° B. (sp. gr. 1.71) in 24 hours, the loss during that period would be 2000 to 4000 lb. of 60° B. acid, whilst about 39,000 lb. of 66° B. acid would be obtained, and the balance of 9208 lb. of 60° B. acid would be recovered in the scrubbers. This scrubber acid is of about 46° B. (sp. gr. 1.47), and is subsequently brought to 60° B. in the Glover tower. The loss of acid varies greatly with the draught, being much greater when a very strong draught is used. The best course is to have only just enough draught to take the distillate from the top of the tower.—C. A. M.

Salt manufacture by solar evaporation of sea water.
L. A. Palmer. Met. and Chem. Eng., 1917, 16, 317—319.

THE process is carried out at San Diego Bay in Southern California, a long and narrow land-locked arm of the Pacific Ocean. The sea water is admitted each fortnight at high tide from the bay to four tide ponds, from which it is transferred by pumps for another two weeks to upper secondary ponds, and then to lower secondary ponds. The calcium carbonate settles out in these ponds, and the liquor is then transferred to the "pickling pond," where calcium sulphate is precipitated. The brine is finally drained to the crystallising pond where the salt is separated, and from this pond the liquor is passed to the bittern ponds. The salt is shovelled into cars, delivering into a bin from which the salt is discharged by a screw conveyor and an elevator into the washer, where it is treated with brine from the pickling pond. It receives a further brine washing and is sprayed with fresh water whilst being elevated to the stack piles, where it is dried.—B. N.

Iodine: The form of — in marine alga. Y. Okuda and T. Eto. J. Coll. Agric., Tokyo, 1916, 5, 341—353.

THIS research demonstrated that by far the greater part of the iodine in the algae investigated was in organic combination. The inorganic iodine was found by the Fresenius method, and to determine the organic form the aqueous extract was acidified with sulphuric acid, filtered, treated with nitrite and chloroform, and the chloroform layer titrated with sodium thiosulphate. Organic iodine in the aqueous solution separated from the chloroform layer was determined by fusing with sodium hydroxide and nitre, and then estimating the iodide formed. The iodine in the sulphuric acid precipitate and in the insoluble residue was also determined by the fusion method. Of the total iodine found in *Ecklonia cara*, 90% was in a soluble organic form, and was not liberated by boiling with dilute sulphuric acid or potassium hydroxide. Fresh samples of *Ecklonia bicyclis* contained under 5% of the iodine in the form of iodide, and 95% organic; of the latter 90% was soluble. The amount of iodine in this plant increases from winter to summer, and old plants contain more than young plants. *Turbinaria fusiformis*, Yendo, *Sargassum enerve*, Ag., and *Sargassum horneri*, Ag., contained respectively 50, 78 and 66 (from different localities), and 66% of soluble organic, and 22, 16 and 17, and 12%, respectively, of the soluble inorganic element. The Japanese food "Dashikombu," made from *Laminaria* by

drying and partially fermenting, contains 95% of its iodine in an inorganic state. Experiments on *Ecklonia bicyclis* showed that it did not contain an enzyme, but some micro-organisms effect its gradual disintegration. Dilute solutions of sodium chloride, calcium chloride, and hydrochloric acid exerted a marked effect on the decomposition of the organic iodine compound in the same plant, as did also concentrated solutions of sulphuric acid and of sodium hydroxide. On heating the *Ecklonia bicyclis* with formalin, some iodine escaped and most of the remainder was converted into the inorganic form: hence boiling with formalin is a simple test for the detection of organic iodine in algae. The soluble organic iodine of *Ecklonia bicyclis* is precipitated by basic lead acetate and by Stutzer's copper reagent, but the chief iodine compound in the extract is not combined with protein. Algae from the open sea apparently contain more iodine than the same species from inland seas. Since the iodine content of dead algae readily diffuses into sea- or fresh-water, drifted algae are not suitable as a source of the element.—E. H. T.

Silicon and its thermoelectric power. F. Fischer and E. Baerwind. Z. anorg. Chem., 1916, 97, 56—72. Z. angew. Chem., 1916, 29, Ref., 536.

OF the two thermoelectrically differing kinds of silicon, the negative form (crystallised from zinc) does not contain, so far as can be shown analytically, more oxygen than the positive. Both have the same specific gravity (2.33). While the existence of two different modifications of silicon is not considered impossible, the authors favour the idea that the differing thermoelectric properties of the negative form are due to the presence of silicon dioxide in solid solution. The two kinds of silicon behave differently in their action as electrical rectifiers. In the analytical work with silicon, evidence was found that it took up oxygen while being ground in an agate mortar.—H. J. H.

Ozone; Determination of —. David. Compt. rend., 1917, 164, 430—431.

THE ozone in air is estimated by adding 5 c.c. of N/100 ferrous ammonium sulphate acidified with sulphuric acid to a vessel of 1 litre capacity, and then titrating back with N/1000 potassium permanganate. For higher concentrations of ozone, N/10 and N/100 solutions respectively may be used.—B. N.

Sulphuric acid chambers. J. Harris, Sheffield, and D. H. Thomas, Morriston, Glamorgan. Eng. Pat. 101,161, Aug. 15, 1916. (Appl. No. 11,517 of 1916.)

A SULPHURIC ACID chamber of circular construction is provided with a pipe for admitting the gases tangentially near the bottom, so as to direct them round the walls, and with a central hollow column extending upwards from the pan and opening at the upper part into the chamber to form an exit pipe for the gases. The central column may be cooled by sprays of weak acid or water directed against it, or by adjacent water-cooled pipes, and in the last chamber of a series it may be packed and supplied with acid to percolate down the packing with the gases, thus replacing part of the absorption towers at the end of the system.—F. Sp.

Lead chambers; Method of firing the walls of — H. Petersen, Berlin-Steglitz. Ger. Pat. 295,911, May 9, 1914.

THE framework supporting the wall is constructed of horizontal and vertical bars, for example of round iron, gas-pipe, or the like. Connecting bands partly or completely encircle the horizontal bars and have their free ends held firmly against the vertical bars by clamping devices. The lead straps attached to the lead wall for the purpose of supporting it on the framework are hook- or ring-shaped and encircle the horizontal bars of the framework. The lead wall may consist of alternate broad and narrow strips, of which only the latter are provided with horizontal rows of straps for fixing to the framework, the broad straps hanging free.

Oxalic acid [from waste paper pulp lyes]; Method of manufacturing — H. C. Reed, Stamford, Conn. U.S. Pat. 1,217,218, Feb. 27, 1917. Date of appl., Sep. 23, 1915.

WASTE liquor from the manufacture of paper pulp is reduced to an approximately dry residue, and concentrated nitric acid added in the proportion of 300 lb. of acid to 100 lb. of residue, the temperature being maintained at about 95° C. until oxidation is complete. Excess of nitric acid and water are then driven off by heat, and the oxalic acid recovered by crystallisation.—T. H. B.

Acetic acid; Preparation of — from acetaldehyde. Badische Anilin u. Soda Fabr. Ger. Pat. 294,724, Feb. 11, 1914.

ACETALDEHYDE is oxidised by air or oxygen in presence of iron compounds and organic salts of alkalis or alkaline earths, including magnesium and aluminium. The reaction is accelerated without the formation of per-acids. It proceeds rapidly and completely in the cold.—H. J. H.

Aluminium nitride; Process for the manufacture of — Soc. Gén. des Nitrures, Paris. Eng. Pat. 101,091, July 25, 1916. (Appl. No. 10,450 of 1916.) Under Int. Conv., Aug. 2, 1915.

AIR is blown through a heated chamber into a narrower passage into which powdered carbon falls from a hopper. The temperature of the air is sufficient to ignite the carbon, the supply of which is adjusted to produce with the air a mixture of carbon monoxide and nitrogen. The hot gases are further heated by passing across one or more electric arcs, and then receive from a hopper a regulated supply of aluminous material (alumina or bauxite) and carbon. If the formation of aluminium nitride is not complete, the mixture is carried through one or more electric arcs to finish the reaction.—F. SP.

Chemical reactions; Process for carrying out — [Preparation of aluminium nitride.] O. Serpek, Assignor to Soc. Gén. des Nitrures, Paris. U.S. Pat. 1,217,842, Feb. 27, 1917. Date of appl., Jan. 26, 1914.

ALUMINIUM nitride is produced by projecting aluminous material and carbon in powdered form through a space through which nitrogen is caused to flow in a direction across the flow of powdered material, the whole being heated to the temperature of the reaction.—F. SP.

Ammonium nitrate and other products; Process of making — F. S. Washburn, New York. U.S. Pat. 1,217,217, Feb. 27, 1917. Date of appl., May 6, 1916.

A MIXTURE of gases containing ammonia and oxygen is subjected to the action of a catalyst at such a rate that the reaction product contains nitrous gases and not more than 20% of free ammonia. A solution of nitric acid and ammonium nitrate is produced from the reaction

product, and free ammonia is added to convert all the nitric acid into nitrate, which may be isolated and treated to yield concentrated nitric acid.—T. H. B.

Flue-dust [from cement-kilns]; Leaching — F. W. Huber and F. F. Reath, Riverside, Cal., Assignors to W. G. Henshaw, San Francisco, Cal. U.S. Pat. 1,220,989, Mar. 27, 1917. Date of appl., Dec. 2, 1916.

POTASSIUM salts are extracted from flue-dust from cement kilns by agitating it with water and then separating the insoluble matter, both operations being carried out at a temperature above 85° C., in order to prevent the formation of the insoluble double salt, $\text{CaSO}_4 \cdot \text{K}_2\text{SO}_4 \cdot \text{H}_2\text{O}$.—A.B.S.

Sulphates and hydrochloric acid; Preparation of — Salzwerk Heilbronn A.-G., and P. Brandenburg, Heilbronn. Ger. Pat. 295,074, July 31, 1915.

FUSED alkali chloride is sprayed by means of sulphuric acid or a mixture of sulphuric acid with air or steam or with sulphur dioxide and steam. Decomposition occurs with the liberation of hydrochloric acid, and alkali sulphate is precipitated as a fine powder.—H. J. H.

Zirconium oxide; Preparation of pure — free from iron. K. Leuchs, Baselmühle. Ger. Pat. 295,246, Aug. 1, 1915. Addition to Ger. Pat. 285,311.

A SOLUTION of crude zirconium oxide in hydrochloric acid is treated with sulphuric acid ($3\text{ZrO}_2 \cdot 2\text{H}_2\text{SO}_4$) and allowed to stand in the cold or at 40° C. Zirconium sulphate separates in small prisms, which are free from iron and also titanium (cf. Hauser, this J., 1904, 677).—H. J. H.

Retort furnace for preparation of hydrogen from iron and steam. W. Näher and M. Nöding, Pforzheim. Ger. Pat. 294,911, May 4, 1915. Addition to Ger. Pat. 290,657 (this J., 1916, 602).

THE retorts used may be disposed horizontally, vertically, or inclined in the furnace and are capable of being easily replaced.—H. J. H.

Sulphur; Production of — O. Urbasch, Vienna. Ger. Pat. 294,912, Aug. 31, 1915.

SULPHUR is produced from materials which yield a portion of their contained sulphur on heating, e.g., pyrites, and spent oxide, by distillation in a vertical retort externally heated with producer gas, the oxygen-free combustion products from which are led through the charge. These combustion products complete the heating and carry away the sulphur in vapour from the condensers. The gases are led in and out of the charge through horizontal pipes which lie across the retort and have openings facing downwards. The residue may be roasted to yield the rest of its sulphur as sulphur dioxide in a muffle furnace below the retort.—H. J. H.

Arsenates; Production of metal — E. C. R. Marks, London, Assignee of T. A. Mitchell, Reading, Mass., U.S.A. Eng. Pat. 101,030, July 21, 1916. (Appl. No. 10,408 of 1916.) Under Int. Conv., July 23, 1915.

SEE U.S. Pat. 1,183,316 of 1916; this J., 1916, 737.

Base-exchanging silicates; Manufacture of — The Permutit Co., Assignees of H. Kriegsheim, New York. Eng. Pat. 101,961, May 11, 1916. (Appl. No. 6765 of 1916.) Under Int. Conv., Mar. 21, 1916.

SEE U.S. Pat. 1,208,797 of 1916; this J., 1917, 215.

Sulphur dioxide: Utilisation of—. J. B. Garner and H. D. Clayton, Pittsburgh, Pa., Assignors to Metals Research Co., New York. Reissue No. 14,277. Mar. 27, 1917, of U.S. Pat. 1,173,566, Feb. 29, 1916. Date of appl. Feb. 8, 1917.

SEE this J., 1916, 469.

Recovery of ammonium chloride in the manufacture of gas or coke. Eng. Pat. 101,942. See IX.

Water-electrolysing apparatus. U.S. Pats. 1,219,813 and 1,220,262. See XI.

VIII.—GLASS; CERAMICS.

Nitre-cake: Utilisation of— [for manufacture of glass]. G. T. Morgan. Econ. Proc. Roy. Dublin Soc., 1917, 2, 238–247.

A METHOD is suggested for the utilisation of nitre-cake which avoids serious loss of either sulphur or alkali and also the difficulties of transit or storage of the nitre-cake itself. If nitre-cake is heated with sand, sulphuric acid is evolved and a soda frit is obtained which, however, still contains some sulphate. Increase of the proportion of sand reduces the amount of residual sulphate, and this is reduced still further by the use of charcoal, sulphur and sulphur dioxide being then formed along with the sulphuric acid. The soda frit may be converted into a glass by melting with suitable oxides, etc. If the use of fluorides is avoided, the recovery of the sulphur and the formation of a glass may be carried out at one operation, the retort being connected with a sulphuric acid plant. In one experiment a mixture of nitre-cake (65 grms.), sand (100 grms.), limestone (18 grms.), and wood charcoal (6 grms.) gave 120 grms. of soda-lime glass, 2.37 grms. of sulphur, and 23.1 grms. of 80% sulphuric acid, the total percentage of sulphur recovered being 52.8. By increasing the quantity of charcoal in this mixture up to 8 grms., the sulphur recovery rose to 66% to 70%; higher amounts of charcoal led to the production of black glasses. In these experiments a nitre-cake was used containing 68.8% of sodium bisulphate. For further experiments on the production of a lead glass, the nitre-cake contained 80% of bisulphate, red lead with a little nitre and borax replacing the limestone and charcoal. Coloured glasses were obtained by the addition of the usual oxides. The efficiency of sulphur recovery was about 66%, as in the case of soda-lime glass, all as sulphuric acid, the oxidising action of the red lead and nitre preventing the separation of sulphur. The time of heating varied in the case of the soda-lime glass from 9 hrs. up to 18 hrs., most of the sulphur being evolved in the first 2 hrs.; in the case of the lead glass the time varied from 4 hrs. to 7 hrs.

IX.—BUILDING MATERIALS.

Setting of litharge-glycerol cement. Merwin. See XIII.

PATENTS.

Building blocks, slabs, and tiles. E. O. C. Howells, Coventry, Eng. Pat. 105,051, Mar. 23 and May 4, 1916. (Appl. Nos. 2101 of 1917 and 6128 of 1916.)

BUILDING materials are made of 6 parts of breeze to 1 of Portland cement with sufficient water to make a paste. One-twelfth of the breeze may be replaced by granite dust where a tougher and denser material is desired. The blocks, etc., have a low sp. gr. and a coarse and open texture and can be produced in larger sizes than when made of other materials.—A. B. S.

Lumber; Material for the preservation of—. P. C. Reilly, Indianapolis, Ind. U.S. Pat. 1,220,001, Mar. 20, 1917. Date of appl. Mar. 28, 1914. Renewed June 9, 1916.

A MIXTURE of coal-tar distillates boiling up to at least 700° F. (about 370° C.) and having a sp. gr. greater than 1.11, is dissolved in a solvent such as the lighter oils produced in the distillation; the remaining distillates of coal-tar boiling up to 1000° F. (about 540° C.) may also be incorporated. —W. E. F. P.

Paving bricks. Method of making bricks and the like. J. W. Tucker, Kissimmee, Fla., and W. A. McCool, Beaver Falls, Pa. U.S. Pats. (A) 1,220,292 and (B) 1,220,293, Mar. 27, 1917. Date of appl. Nov. 20, 1916.

(A) BRICKS or blocks are made by impregnating comminuted non-resinous wood (as cypress) with a light or thin asphaltum and uniting these into a solid mass by means of a heavier asphaltum. (B) The material is prepared as in (A) but any suitable light and heavy "hydrocarbon material" may be substituted for the asphaltum, and heavy pressure is used when forming the material into bricks.—A. B. S.

Cement; Water- and acid-proof— and process of making same. U. Wedge, Ardmore, Pa., Assignor to Electro-Chemical Supply and Engineering Co., Philadelphia, Pa. U.S. Pat. 1,220,575, Mar. 27, 1917. Date of appl. Mar. 1, 1915.

SILICIOUS material is mixed with an acid and afterwards with sodium silicate. The acid decomposes the silicate and precipitates finely divided silica which makes the cement water- and acid-proof.—A. B. S.

Building material; Waterproof—. A. C. de Caudenberg, Nice, France. U.S. Pat. 1,220,401, Mar. 27, 1917. Date of appl. Nov. 29, 1913. Renewed Aug. 10, 1916.

SEE Fr. Pat. 451,618 of 1912; this J., 1913, 605.

Hydraulic lime and cement; Production of— from combustion residues of sewage, canal-sludge, or the like. J. Elsner, Berlin-Friedenau, Germany. U.S. Pat. 1,220,735, Mar. 27, 1917. Date of appl. Dec. 26, 1913. Renewed Jan. 29, 1917.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Bessemer and open-hearth practice: Temperature measurements in —. G. K. Burgess. Trans. Amer. Inst. Min. Eng., 1917, 293—306.

THE most satisfactory instrument for controlling furnace and casting temperatures is an optical pyrometer using monochromatic light and permitting observations from a distance. The corrections to the observed pyrometer readings for emissivity of iron ($e=0.10$ for red light) and liquid iron oxide ($e=0.53$) are sufficiently well known to allow of correct results being obtained, but there may be uncertainty in the case of liquid slags (e =usually about 0.65). Temperature measurements of Bessemer converter charges are not deemed practicable by pyrometric methods. The open-hearth furnace can be controlled by observing the temperature of the roof of the metal bath, and of the slag through ports. The temperature of the roof, which may vary rapidly and within wide limits, does not necessarily bear any relation to that of the bath, which is usually kept between 1600° and 1670° C. The temperature of the metal may be ascertained fairly accurately from a sample taken with a spoon. A series of temperatures observed in practice are tabulated.—W. R. S.

Steel; Spontaneous generation of heat in recently hardened —. C. F. Brush and R. A. Hadfield. Proc. Roy. Soc., 1917, A, 93, 188—211.

STEELS of various types were found to generate measurable quantities of heat spontaneously, but at a steadily diminishing rate, for a considerable time after being quenched at a high temperature and hardened. Curves and tables are given showing the results obtained with carbon tool and "high-speed" tungsten-chromium steels over periods of 150 hrs., and the rate of such heat generation in nickel-chromium steels during periods of 24 hrs. Under the heat-insulating conditions of the experiments, an actual rise of temperature of 1.1° C. was clearly observed in some cases; but it is pointed out that in practice the heat evolved has every facility for dispersing without increasing the temperature of the steel. The evolution of heat appeared to be unaccompanied by chemical change, since the hardness of the specimens was not affected; but it is pointed

of strain or molecular rearrangement, doubtless accompanied by a further generation of heat, and so on until annealing is effected.—W. E. F. P.

Ferro-uranium. H. W. Gillett and E. L. Mack. J. Ind. Eng. Chem., 1917, 9, 312—317.

A DESCRIPTION is given of experiments carried out with the object of obtaining iron-uranium alloys. By using pure uranium dioxide, a low-ash coke, and pure iron as raw materials it is possible, employing a titling, direct arc type furnace with water-cooled magnesite hearth and sides, to produce a ferro-uranium of any desired uranium content (10 to 70%), with carbon below 2%, silicon below 0.75%, vanadium below 0.5%, and traces of aluminium, sulphur, phosphorus, and manganese. If experiments with such a ferro-uranium show that uranium steels high in uranium are not valuable, but that a little uranium is useful, and if the amount required is so low that the carbon introduced by the ferro-uranium is harmless, then the furnace might have an uncooled hearth and the ferro-uranium would contain 1 to 5% of carbon.—W. P. S.

Current density in copper refining. L. Addicks. Met. and Chem. Eng., 1917, 16, 311—315.

IN general, the temperature of the electrolyte should be raised as near 150° F. (65.5° C.) as possible in order to employ as high a current density as may be desirable from the point of view of cost of operation; heating of the electrolyte by exhaust steam will be necessary to maintain this temperature, unless a very high density, permitted by very unusual conditions, is employed. The relations between the power cost, cost of plant, age of electrodes, metal tied up, and the current density are discussed, with the view of showing the points to be considered in designing an electrolytic plant. These general relations between current density and cost are summarised in the following table, for five localities where the probable power cost is estimated at $\frac{1}{10}$ c., $\frac{1}{8}$ c., $\frac{1}{6}$ c., $\frac{1}{4}$ c., and 1 c. per kilowatt-hour respectively. It is assumed that the gain from released heat just offsets the loss from decreased current efficiency as the density is raised; that the interest and depreciation on the tank house and power plant are 20% per annum; that the silver and gold values in the anodes amount to \$100 a ton; and that other conditions are equal.

Current density.	Kw. hrs. per ton.	\$ Investment per ton—day.	Cost in dollars per ton.						Dollars per ton									
			Interest and depreciation.	Metal interest.	Metal loss.	Labour.	Power.		Total operating cost.									
									$\frac{1}{10}$ c.	$\frac{1}{8}$ c.	$\frac{1}{6}$ c.	$\frac{1}{4}$ c.	1 c.	$\frac{1}{10}$ c.	$\frac{1}{8}$ c.	$\frac{1}{6}$ c.	$\frac{1}{4}$ c.	1 c.

out that the present methods of determining hardness give only approximate values. The results obtained are regarded as showing that hardened steel is in a condition of very great molecular strain and somewhat unstable, especially at first, after being quenched. Spontaneous relief of a small portion of the strain causes generation of heat until stability at atmospheric temperature is reached. Any considerable rise in temperature, as in tempering, permits further spontaneous relief

The figures worked out for total costs are not the actual costs of refining, but simply totals which vary as the actual costs will when the density is varied. The density which will give the minimum cost for each power cost, may be found from the curves in Fig. 1, in which the density is plotted against the variation in total operating costs. These minima are again plotted against the current in the curve marked "theory" in Fig. 2, and the curve found in practice is added

FIG. 1.

for comparison. The two curves agree well except at the lower power costs, where practice runs at a higher current density than would be expected, and this is due largely to the fact that although a certain density may show minimum

FIG. 2.

cost, a higher density may show maximum profits owing to a greater quantity of copper being treated by the plant at the higher density.—B. N.

Zinc; Determination of.—J. H. Hastings. *Met. and Chem. Eng.*, 1917, 16, 263—265.

SOLUTION of the ore and separation of iron and manganese are effected as usual, the zinc being determined by titration with standard potassium ferrocyanide in a boiling, slightly acid solution (volume about 200 c.c., containing 5 c.c. excess of hydrochloric acid) containing hydrogen sulphide, a saturated aqueous solution of which (50 c.c.) is added to prevent decomposition of the ferrocyanide by oxidising agents and precipitate any small quantity of copper present. A 5% solution of uranium nitrate is employed as external indicator.—W. E. F. P.

Aluminium dust; Analysis of.—J. E. Clennell. *Eng. and Min. J.*, 1917, 103, 496—499.

ONE GRM. is dried at 100° C. to constant weight and the loss reported as moisture. The dried material is transferred to a dry 200 c.c. beaker and washed with ether till free from grease. The filtered extract is evaporated in a tared flask and the grease weighed. The residue from the extraction is transferred to a 300 c.c. flask and dissolved

in dilute hydrochloric acid; the hot acid solution is filtered through the filter previously used into another flask, and the filter washed with hot water. The insoluble residue is washed back and treated with nitric acid; this solution is filtered through the same filter into a separate flask. The ignited insoluble residue consists of silica mixed with some carbon which resists ignition very persistently. It is fused with a small quantity of sodium peroxide and the silica separated as usual; this is calculated to silicon. The nitric acid filtrate is evaporated with sulphuric acid and added to the main hydrochloric acid filtrate. This is precipitated with hydrogen sulphide, and the precipitate digested with hot 50% hydrochloric acid to separate copper and lead. The residual copper sulphide is dissolved in nitric acid and the copper titrated with cyanide. The lead solution is neutralised with ammonia, acidified with acetic acid, and precipitated with bichromate. The filtrate from the hydrogen sulphide precipitate is oxidised and treated with excess of caustic soda; the precipitate is dissolved and re-precipitated with ammonia; the filtrate from the ferric hydroxide is used for the estimation of magnesium. The alkaline filtrate containing aluminium and zinc is precipitated with sodium sulphide, and the zinc sulphide determined with N/10 iodine and thiosulphate. The aluminium may be roughly determined by acidifying the last filtrate, expelling hydrogen sulphide by boiling, making up to 500 c.c., and titrating 100 c.c. with N/1 alkali first with methyl orange, and then with phenolphthalein as indicator. The interval between the two end-points is proportional to the aluminium; the alkali is standardised against pure aluminium. Special methods for the separate determination of the impurities are also described.—W. R. S.

Aluminium and carbon. O. Ruff and E. Jelinek; *Z. anorg. Chem.*, 1916, 97, 312—336. *Z. angew. Chem.*, 1916, 29, Ref., 536.

PURE aluminium shavings were heated with the theoretical quantity of finely powdered ash-free carbon for 30 minutes at 2000° C. in a closed carbon crucible in an atmosphere of nitrogen-free hydrogen. The dark orange-coloured product contained, in addition to the carbide, Al_4C_3 , some aluminium or a carbide less rich in carbon. With hydrochloric acid it gave a mixture of methane and hydrogen containing 7.7% of the latter. A grey-coloured carbide, approximately Al_3C_2 , can be prepared by heating a mixture of aluminium and carbon in the calculated proportions. Under atmospheric pressure at 2200° C., the carbide, Al_4C_3 , dissociates into the elements, the carbon being graphitic; vapours of carbide are given off and these are richer in carbon, the higher the temperature and pressure. Curves are given in the original showing the relation between the composition of the carbide vapours and the temperature and pressure.—H. J. H.

"Thiogen" process for removing sulphur [dioxide from smelter] fumes. S. W. Young. *Amer. Inst. of Chem. Eng. Met. and Chem. Eng.*, 1917, 16, 309—310.

THE process has been designed for reducing the sulphur dioxide from smelter furnaces to free sulphur, by means of petroleum hydrocarbons or other carbonaceous material. In the dry process, the sulphur dioxide and hydrocarbon vapours are passed over a catalytic agent, such as plaster of Paris, at a bright red heat, the calcium sulphate being reduced to sulphide by the hydrocarbons, and again oxidised to sulphate by the sulphur dioxide. It has been found that the gas must contain at least 7% of sulphur dioxide for successful working, and that the gases must be preheated before passing over the contact material. In the

wet process, the sulphur dioxide is absorbed by water in towers, and the solution mixed with a paste or solution of a suitable sulphide, such as barium sulphide, thus forming a sludge which contains free sulphur and complex insoluble sulphur salts. The sludge is settled, filtered, dried, and heated to 450°–500° C. to distil off the sulphur, the residue being afterwards reduced to sulphide in a furnace. Barium sulphide is preferable to the cheaper calcium sulphide, as it is very soluble, gives insoluble sulphur salts, and the barium salts crystallise in the anhydrous state, an advantage in the last stage of the process where the free sulphur is distilled off.—B. N.

By-product coke and coking operations. Ramsburg and Sperr, jun. See IIa.

Accurate determination of silica in commercial analysis. Hawley. See XXIII.

PATENTS.

Steel-making and like furnaces or mixers. Wellman, Seaver and Head, Ltd., London, and R. Gray, Redcar, Yorks. Eng. Pat. 104,657, Nov. 29, 1916. (Appl. No. 17,147 of 1916.)

IN steel furnaces or mixers in which a port structure is used to give communication between the furnace port and the port of the regenerator (see Eng. Pat. 23,245 of 1908) and in which a double seal is used between the port structure and the regenerator, the end of the port structure opposite the regenerator is protected by a cooling device or water-jacket which may be a continuation of the upper seal trough.—W. R. S.

Steel-making process. G. G. McMurtry, New York. Assignor to United States Steel Corporation, Hoboken, N.J. U.S. Pat. 1,217,972, Mar. 6, 1917. Date of appl., Jan. 27, 1915.

STEEL is treated first with a basic slag and then with an acid slag in the same furnace having a lining of zirconia.—W. F. F.

Iron ores; Process of treating —. T. S. Maffitt, St. Louis, Mo., Assignor to Mississippi Valley Iron Co., Wilmington, Del. U.S. Pat. 1,219,338, Mar. 13, 1917. Date of appl., May 9, 1916.

THE ore with its gangue is subjected to the action of heat in the presence of a reducing agent, such as gas containing carbon or hydrocarbons. The iron is thus rendered magnetic and is separated magnetically from the gangue before the temperature has fallen below 450° F. (about 230° C.).—J. H. J.

Cast-iron; Method of making —. H. W. Lash, Cleveland, Ohio. Assignor to The West Coast Iron Co. U.S. Pat. 1,220,349, Mar. 27, 1917. Date of appl., Nov. 21, 1912.

STEEL scrap is melted under non-oxidising conditions, in a reverberatory furnace, with a mixture of carbonaceous material, silica, and finely divided cast-iron in equal proportions.—W. E. F. P.

Iron; Composition for polishing —. M. Yasuda, Koishigawa, Japan. U.S. Pat. 1,216,643, Feb. 20, 1917. Date of appl., Mar. 14, 1914.

A COMPOSITION for polishing iron consists of 3 parts by weight of dehydrated alum. 2 parts by weight of finely divided uncoated metallic aluminium, and 5 parts by weight of powdered crystalline silica, the ingredients being in intimate contact and capable of reacting with each other and with the iron rust.—T. H. B.

Iron and steel; Process for rust-proofing —. W. H. Allen. Assignor to Parker Rust Proof Co. of America, Detroit, Mich. U.S. Pat. 1,219,526, Mar. 20, 1917. Date of appl., Sep. 25, 1916.

AFTER treatment with a hot, aqueous solution of phosphoric acid to remove the scale, the articles,

while still wet, and without preliminary washing, are immersed in an aqueous solution of acid ferrous and ferric phosphates until black basic phosphates of iron are formed upon their surfaces.—W. E. F. P.

Ferrophosphorus; Process of producing — from *nelsonite*. J. J. Gray, jun., Rockdale, Tenn. U.S. Pat. 1,216,306, Feb. 20, 1917. Date of appl., June 26, 1916.

A CHARGE of carbon and nelsonite ore containing tricalcium phosphate, iron oxide, titanium oxide, and alumina is mixed with phosphatic material and silica in excess, and smelted at a constant temperature in a blast-furnace so as to cause a maximum reduction of iron oxide, indirectly, and also a direct maximum reduction of the phosphate, without fluxing the titanium oxide. A reducing atmosphere is maintained throughout. After fluxing and smelting, the charge is followed by one of iron ore, basic material, and coke. The process is designed to prevent the "dirty hearth" usually produced in making ferrophosphorus in the blast-furnace.—T. H. B.

Aluminium; Production of —. E. E. P. J. P.S.J. de St. Laurent, Twickenham, Middlesex, and R. D. Mackintosh, Mortlake, Surrey. Eng. Pat. 11,820 of 1915; date of appl., Mar. 16, 1916.

DRIED and powdered clay, made into a thick cream with acidified distilled water, is treated with superheated steam, whereby the impurities are rendered insoluble and a solution is obtained from which pure aluminium hydroxide is subsequently precipitated by ammonia. The washed and dried precipitate is reduced by heating with carbonaceous matter.—W. E. F. P.

Metallic compounds [aluminium] from carbides; Production of —. P. R. Hershman, Chicago, Ill., Assignor to The Mineral Products Co., New York. U.S. Pat. 1,220,843, Mar. 27, 1917. Date of appl., Dec. 21, 1914.

To produce metallic aluminium from aluminium carbide, the latter is heated to about 2200° C., in the presence of a small amount of an aluminium compound to facilitate decomposition, until the charge begins to melt, when the temperature is lowered to about 2100° C. Alternatively, the carbide is heated under pressure in the presence of a gas containing hydrogen which has no influence on the decomposition.—W. E. F. P.

Metal [tin] from scrap or waste sheet metal or sheet metal articles; Recovery of —. H. A. Leaver, Westcliff, Essex, and H. H. Hosack, Twickenham, Surrey. Eng. Pat. 13,168 of 1915; date of appl., Mar. 15, 1916.

IN an electrolytic detinning process, the waste metal is conveyed through the electrolyte on a horizontal, endless rubber band. The surface of the band is provided with inter-connected, metal parts constituting the anodes upon which the material rests and to which the current is supplied; and a number of vertical, stationary cathodes are arranged in the electrolytic tank on each side of the conveyor.—W. E. F. P.

Concentration of ores; Apparatus for —. Minerals Separation, Ltd., London. From Minerals Separation and De Bavay's Processes Australia Proprietary, Ltd., Melbourne. Eng. Pat. 104,366, Feb. 26, 1916. (Appl. No. 2902 of 1916.)

THE level of liquid in a separating vessel forming part of an apparatus for the concentration of ores by the froth flotation process, is controlled by a device comprising the combination of a float in the separating vessel, a cock on the air-inlet pipe, and an operative connection between them, so

that the air supply is reduced as the level of the liquid falls. A number of flotation vessels and centrifugal pumps are arranged in series, and each pump withdraws material from the bottom of one vessel, agitates it, and delivers it to the next flotation vessel, the delivery of the pumps being controlled as described.—T. H. B.

Concentration of ores; Apparatus for —.
Minerals Separation, Ltd., London. From F. J. Lyster, Broken Hill, N.S.W. Eng. Pat. 101,367, Feb. 26, 1916. (Appl. No. 2903 of 1916.)

WITHIN a separating box of rectangular form having an outlet for tailings at the bottom, and an overflow at the top, both discharging into launders, are arranged two hollow vessels, adjustable in height, with their open lower ends immersed in the liquid and their upper edges a little above the level of the liquid; these vessels are cylindrical at their lower portions and conical at the upper part, with launders round their upper edges. The ore pulp, together with a frothing agent, such as eucalyptus oil, passes from a feed box above the separating box, through pipes extending down into the hollow vessels, and discharging below the surface of the liquid. These pipes are provided with air inlets near the upper end, through which air is sucked in by the flowing pulp, and baffle-plates are fixed within the hollow vessels immediately under the ends of the pipes, in such a position that emulsification of the pulp is ensured. The froth of concentrates floats to the surface of the liquid in the hollow vessels and overflows into the launders, and the excess liquor overflows from the separating box and is returned to the circuit.—T. H. B.

Ores; Apparatus for separating — by flotation.
H. E. T. Haultain, Toronto, Canada. U.S. Pat. 1,218,400, Mar. 6, 1917. Date of appl. Apr. 19, 1915.

A RECEPTACLE for the mixed pulp discharges on to a number of substantially triangular, overlapping, inclined and closely set plates. The plates are arched in cross-section so as to spread the pulp in fan shape. The pulp is discharged into a second receptacle, and currents of air are blown on to its surface in front of the inclined plates from a series of nozzles. An overflow discharge is also provided in the second receptacle.—W. E. F.

Concentrating ore; Method and apparatus for —.
H. M. Dunn, Hurley, N. Mex. U.S. Pat. 1,219,089, Mar. 13, 1917. Date of appl. May 11, 1915.

IN an agitation-froth process, a mixture of ore pulp and frothing agent is passed continuously, by means of a current of air, into the lower part of the frothing compartment of a separator. This compartment has a concave side against which the stream of ore is delivered, so that on this side the pulp is raised to a higher level than that of the bulk and receives additional aeration in falling back upon the main surface.—W. E. F. P.

Magnetic ores; Method and apparatus for separating —.
J. Weatherly, Assignor to Electric Ore Separator Co., New Cumberland, Pa. U.S. Pat. 1,218,916, Mar. 13, 1917. Date of appl. June 12, 1915.

THE ore in the form of small particles is carried by a travelling belt between two electromagnets, the poles of which are of opposite sign, and are alternately and rapidly reversed so that the magnetic particles are caused to rotate and thus detach themselves from the non-magnetic particles. The ore is then subjected to a magnetic field between pole-pieces of the same but rapidly alternating polarity, so that the magnetic particles repel one another and settle in a surface layer on the non-magnetic particles.—W. E. F.

Zinc, lead, and sulphur from sulphide ores; Recovery of —.
F. H. Haviland, London, Eng. Pat. 101,516, Jan. 3, 1916. (Appl. No. 86 of 1916.)

ZINC sulphide ore mixed with an excess of carbon is heated in a furnace with a flame of reducing gas mixed with not more than the required amount of air to cause combustion of the nascent hydrogen or hydrogen sulphide which is formed; free sulphur is thus produced, and the zinc is reduced and volatilised. The fume from the furnace is subjected to electrostatic precipitation in two stages to separate first the zinc in liquid form, and then the sulphur, preferably in separate chambers. The ore may be desulphurised in a furnace as described and the oxidised residue transferred to an electric furnace to recover the zinc. If the ore contains lead, the volatilised metals are fractionally precipitated as oxides in separate chambers by electrostatic means. The sulphur and zinc may be precipitated together and subsequently separated.—W. R. S.

Zinc; Extraction of —.
H. L. Sulman, H. F. K. Picart, and The Metals Extraction Corporation, Ltd., London, Eng. Pat. 101,697, Jan. 22, 1916. (Appl. No. 1063 of 1916.)

IN a cyclic process, successive small quantities of powdered, oxidised zinc ore are agitated with a 10% solution of sulphuric acid until the acidity of the liquid is reduced to between 1 and 2%, when neutralisation is completed quickly by agitation with the requisite quantity of zinc hydroxide (obtained in a previous operation); in the presence of decomposable silicates the mixture is preferably maintained at 90°–100° C. The neutralised pulp is then filtered, the strong solution of zinc sulphate being treated to remove copper, cadmium, and iron, and finally electrolysed for the recovery of zinc and regeneration of the acid solvent; the residue is washed with water and the washings treated with milk of lime to precipitate zinc hydroxide for subsequent use in neutralisation.—W. E. F. P.

Zinc; Condenser in the metallurgy of —.
J. Thomson, New York, and F. A. J. FitzGerald, Niagara Falls, Assignors to John Thomson Press Co., Jersey City, N.J. U.S. Pat. 1,219,193, Mar. 13, 1917. Date of appl. June 21, 1916.

THE lower end of an inclined condenser communicates with a receptacle for liquid zinc, the condenser and receptacle being enclosed in a single structure but provided with separate heating flues. The flow of zinc fume and the temperature of the condenser are controlled so that condensation is practically complete at 750°–700° C.—W. E. F. P.

Zinc-distilling furnace; Electric —.
J. Thomson, New York, and F. A. J. FitzGerald, Niagara Falls, Assignors to John Thomson Press Co., Jersey City, N.J. U.S. Pat. 1,219,194, Mar. 13, 1917. Date of appl. June 21, 1916.

THE heating chamber of an electric distilling furnace is divided into upper and lower communicating compartments by a slightly inclined, transverse partition having an opening at the lower end. The lower or distillation compartment contains a suspended resistor which is enclosed by an open-bottom casing on the top of which a layer of granular carbon is disposed; and vertical flues, communicating with the interior of this casing by means of openings in the vertical sides, are provided between the latter and the furnace walls. The zinc fume from the interior of the resistor casing is thus caused to pass around the latter before entering the upper or fume compartment on its way to the condenser.—W. E. F. P.

Furnaces; Pot — for melting metals. Gibbons Bros., Ltd., and R. Masters, Lower Gornal, Staffs. Eng. Pat. 101,583, May 1, 1916. (Appl. No. 6167 of 1916.)

Two or more pot furnaces are combined in a brick-work structure, each furnace having an up-cast or down-cast waste heat flue and a down-cast hot air flue or flues arranged at the side of the waste heat flues or between these and the furnaces. The hot air flues have air inlets at their upper ends and are connected at their lower ends with closed ash-pits under the fire-bars.—W. R. S.

Furnace; Open-hearth —. N. Thomas and A. W. Allen, Birmingham, Ala. U.S. Pat. 1,217,367, Feb. 27, 1917. Date of appl., Dec. 16, 1915.

THE hot gases pass upward from a common inlet through a number of vertical flues connected at the top at an acute angle to extensions which are inclined downward toward the furnace hearth. A supply of fluid may be delivered to each flue by a pipe which passes through the end wall of the furnace and extends into and parallel with the inclined part of the flue, terminating short of the flue outlet.—W. F. F.

Furnace; Basic open-hearth —. S. Naismith, Chicago, Ill. U.S. Pat. 1,220,441, Mar. 27, 1917. Date of appl., Apr. 17, 1916.

IN a basic open-hearth furnace, a series of removable water coolers is disposed in the walls at the s'ag line and close to the lining; the weight of the walls is borne by a series of external buck stays.—W. E. F. P.

Rabble for mechanical roasting-furnaces. W. Hommel, Zürich, Switzerland. U.S. Pat. 1,220,513, Mar. 27, 1917. Date of appl., Aug. 23, 1916.

IN a rabble (see fig.) having two series of scraper blades arranged alternately and provided with inclined working faces perpendicular to the hearth level, each blade has an outwardly and down-

wardly inclined face, *c*, forming a sharp cutting edge, *g*, with the base. The blades are connected with each other by bridge-like stays, *i*; a vertical web, *m*, terminating in a cutter, adjoins each outer cutting face; and a small, inclined face, *o*, adjoins each of the outer cutting edges, *g*.
—W. E. F. P.

Ores; Process of treating —. G. F. Downs, Buffalo, N.Y. U.S. Pat. 1,216,667, Feb. 20, 1917. Date of appl., Dec. 7, 1914.

THE ore is fed into the upper end of a slightly inclined rotating cylinder, through which it moves longitudinally and at the same time has a transverse tumbling movement. The ore is progressively heated by hot gases moving through the cylinder in the opposite direction, and finally passes into a part of the cylinder where it is subjected to blasts of air or other gas, so directed as to produce violent radial agitation and thereby facilitate chemical reaction between the ore and the gas.—W. F. F.

Oxide ores of copper; Process of concentrating —. R. Gahl, Miami, Ariz. U.S. Pat. 1,217,437, Feb. 27, 1917. Date of appl., Dec. 27, 1916.

COPPER is dissolved from the ore by acid and

precipitated by metallic iron, undissolved iron is separated magnetically from the pulp, and the residue containing cement copper is subjected to flotation.—T. H. B.

Clad metals; Process of making —. B. E. Eldred, New York, Assignor to The Commercial Research Co. U.S. Pat. 1,217,581, Feb. 27, 1917. Date of appl., Jan. 21, 1910. Renewed Feb. 10, 1916.

A BODY of steel is placed in a mould and a body of copper placed in contact therewith and the temperature is raised until the copper melts. The mould and contents are then cooled from below by abstraction of heat from the bottom, while still heating the rest of the mould, so that the topmost layer is the last to solidify.—T. H. B.

Metallic compound. H. B. Coho, Mount Vernon, N.Y., Assignor to United Lead Co. U.S. Pats. (A) 1,217,710, and (B) 1,217,711, Feb. 27, 1917. Dates of appl., June 7, 1915, and July 29, 1916.

(A) A MIXTURE of lead, copper, tin, and antimony sulphide. (B) A mixture of lead and copper is fused with antimony sulphide associated with sodium.—W. F. F.

Metallurgical process. [Electrolysis of fused copper sulphide.] W. E. Greenawalt, Denver, Colo. U.S. Pat. 1,218,177, Mar. 6, 1917. Date of appl., Nov. 23, 1912. Renewed Jan. 17, 1917.

COPPER sulphide is fused at a high temperature and subjected to electrolysis to separate the metal from the sulphur. Steam and reducing gases are applied to the highly heated liberated sulphur to form hydrogen sulphide.—W. F. F.

Lead and molybdenum; Process for separating — from mineral wulfenite. A. Kissock, Tucson, Ariz. U.S. Pat. 1,218,412, Mar. 6, 1917. Date of appl., Dec. 11, 1915.

LEAD molybdate (wulfenite) is mixed with carbon and a suitable flux such as soda ash, and heated in a furnace to a state of quiet fusion, when metallic lead and a slag containing sodium molybdate are produced, and are separately withdrawn. The slag is cooled, ground in a suitable crusher, and mixed with carbon and silica, with or without iron. The mixture is again heated to quiet fusion, and the metallic molybdenum and slag produced are separately withdrawn.—W. F. F.

Ores; Process for extracting metals from their —. W. E. Greenawalt, Denver, Colo. U.S. Pat. 1,218,996, Mar. 13, 1917. Date of appl., June 1, 1915.

THE ore is charged into a vertical cylinder, in which it is roasted by a blast. The lower end of the cylinder is submerged in a tank containing an acid solvent. The roasted ore is cooled and wetted while still in the vertical column, and transferred from the lower end to the extracting solution. The exhausted ore is continuously withdrawn from the tank, means being provided for removing the sands and slimes separately.—W. R. S.

Ores; Automatic controlling system for continuous agitation and transfer systems for treatment of —. J. W. Bucher and R. P. Akins, Assignors to Colorado Iron Works Co., Denver, Colo. U.S. Pat. 1,219,210, Mar. 13, 1917. Date of appl., Oct. 7, 1915.

A CONTINUOUS flow of pulp is made to circulate through a series of communicating tanks in one direction and a continuous flow of solvent in the opposite direction. The transfer and supply of pulp and solution from one tank to another is controlled automatically. Air under pressure is used for agitating and transferring the liquors.

—W. R. S.

Blast-furnace gases; Process of preheating —. O. Oesterlen, Zweibrücken, Germany. U.S. Pat. 1,219,852, Mar. 20, 1917. Date of appl. Apr. 1, 1915.

A PORTION of the filtered or unfiltered waste gases from blast-furnaces is burnt in preheaters through which the main volume of the gases is conducted before being burned in the hot blast ovens.

—W. E. F. P.

Separator and amalgamator; Centrifugal —. H. R. Zimmer, Los Angeles, Cal. U.S. Pat. 1,220,051, Mar. 20, 1917. Date of appl. Aug. 4, 1914.

ORE is fed from a hopper to the bottom of a rotating bowl containing mercury. The bowl is provided with superposed annular shelves, the edges of which are bevelled downward and inward. The top of the bowl projects inward forming a vertical wall, so that a pocket is formed with the uppermost shelf for the reception of the amalgam. The ore-feed pipe carries an inner adjustable stationary bowl, having a vertical wall at the top, a passage-way being formed between this wall and the vertical wall of the rotating bowl.—W. E. F.

Process and means for filtering [jewellers' waste wash] water. U.S. Pat. 1,217,397. See XIXB.

XI.—ELECTRO-CHEMISTRY.

Silicon and its thermoelectric power. Fischer and Baerwind. See VII.

PATENTS.

Furnace-wall construction; Electric —. I. Hechenbleikner, Charlotte, N.C., Assignor to Southern Electro-Chemical Co., New York. U.S. Pat. 1,217,306, Feb. 27, 1917. Date of appl. Sep. 27, 1915.

THE body of the furnace is water-cooled and connected to a tapered non-cooled portion above, which in turn is connected to a non-cooled elbow section, the connections being made by channel steel sections bolted together. A lining of chilled slag, substantially uniform in thickness, extends completely around the sides and over the bottom of the water-cooled and non-cooled parts.—B. N.

Furnace; Electric —. C. A. Pfanstiehl, Waukegan, Ill., Assignor to Pfanstiehl Co., U.S. Pat. 1,217,497, Feb. 27, 1917. Date of appl. July 11, 1914.

A TUBE of refractory, porous, heat-resisting material, such as alundum, forming a heating chamber, is surrounded by a steel shell so as to form an annular space into which hydrogen is passed, and the shell is embedded in heat-resisting material contained in an outer receptacle. The hydrogen percolates through the tube into the heating chamber. A carbon resistance element, of substantially semicircular cross-section, is disposed within the alundum tube, and arranged to support articles to be treated in the heating chamber. The resistance element is heated by an electric current, connected through terminals provided with channels for the passage of a current of cold water.—B. N.

Furnaces; Terminal for electric —. T. F. Baily and F. T. Cope, Assignors to The Electric Furnace Co., Alliance, Ohio. U.S. Pat. 1,218,042, Mar. 6, 1917. Date of appl. Apr. 27, 1915.

THE terminal of the furnace is composed of an electrode surrounded by loose refractory material in a container with means for supporting and insulating the container from the furnace. Laminated conductor strips are connected to a supply main, the extremities of the strips being located upon each side of the electrode, with

metal blocks between each strip and the adjacent side of the container. A plate is located upon each side of the container, adjacent to the metal blocks, with means for drawing the plates towards each other.—B. N.

Furnace; Electric —. F. T. Cope, Assignor to The Electric Furnace Co., Alliance, Ohio. U.S. Pat. 1,218,058, Mar. 6, 1917. Date of appl. Apr. 27, 1915.

A REFRACTORY trough, containing a granular resistance material, is supported within the heating chamber of the furnace by spaced walls disposed transversely, so that the trough is spaced upon all sides from the upper, lower, and side walls of the furnace, and circulation of air is thus allowed transversely around the trough between the spaced walls.—B. N.

Induction furnace; Electric —. P. Wright, Vancouver, British Columbia. U.S. Pat. 1,218,151, Mar. 6, 1917. Date of appl. May 11, 1914.

THE furnace comprises a core and winding, the core being surrounded by a secondary coil provided with an element of good electrical-conducting material, such as copper, and having enlarged terminal electrodes at the ends. A cast-iron chambered resistor, closed at its ends by the electrodes, is in circuit with the latter, and is adapted to hold a body of melted metal between the electrodes and in contact with them.—B. N.

Furnace; Electric —. C. A. Pfanstiehl, Waukegan, Ill., Assignor to Pfanstiehl Co., North Chicago, Ill. U.S. Pat. 1,218,582, Mar. 6, 1917. Date of appl. Apr. 15, 1915.

A HOLLOW cylindrical tube of alundum is provided on its outer surface with a glaze impervious to air or gas, and a wire for conducting the electric current is coiled helically within the tube, substantially in contact with the inner walls. The interstices between the coils are filled with a refractory cement, so as to form a smooth cylindrical inner surface, and the open ends are stopped by refractory plugs. A supply of hydrogen is conveyed by pipes to and from the interior of the tube.—B. N.

Battery [; Electric —]. J. M. Flannery, Pittsburgh, Pa. U.S. Pats. (A) 1,217,738 and (B) 1,217,739, Feb. 27, 1917. Date of appl. May 3, 1916.

(A) AN ioniser for electric batteries comprises a thin sheet of perforated celluloid, insoluble in the electrolyte, and carrying radioactive material incorporated in it. (B) An ioniser comprises a perforated separator for the plates of the battery, with a coating of radioactive material carried in an insoluble vehicle.—B. N.

Electrode for generating pure oxygen. J. F. Sanders, Assignor to O. P. Coshov, Roseburg, Oreg. U.S. Pat. 1,218,584, Mar. 6, 1917. Date of appl. Aug. 4, 1915.

A COMPOUND electrode is composed of hydrogen-absorbing porous palladium, and a catalyst of rhodium, adapted to make the palladium give up its hydrogen when brought into contact with oxygen in solution.—B. N.

Water-electrolysing apparatus. R. J. J. Mueller, Chicago, Ill., and E. G. Rowlands, Milwaukee, Wis., Assignors to Universal Oxygen Co. U.S. Pat. 1,219,843, Mar. 20, 1917. Date of appl. Mar. 21, 1913.

A DEEP metal tank is divided into communicating compartments by vertical partitions which form, with the sides, a series of electrodes of the same polarity; the tank has an arched, metal cover from which depend a number of metal plates, one nearly to the bottom of each compartment, forming

a corresponding series of electrodes of opposite polarity. The cover is insulated from the tank by a diaphragm through openings in which the metal plates extend; and each plate is surrounded by a tube of flexible, non-corrodible material, the latter being pervious to liquid but impervious to gas when wet and depending from the under side of the diaphragm. The arrangement is such that, during operation, the gases evolved at the cover and tank electrodes are collected separately above and below the diaphragm respectively.—W. E. F. P.

Water-electrolysing apparatus. R. J. J. Mueller and E. G. Rowlands, Sheboygan, Wis., Assignors to Universal Oxygen Co. U.S. Pat. 1,220,262, Mar. 27, 1917. Date of appl. Jan. 2, 1914. Renewed Jan. 17, 1917.

A CELL for the electrolysis of water consists of a tank, constituting one electrode: a neutral member forming an extension to the upper part of the tank but insulated from it: and a cover resting upon but insulated from the neutral member, and forming the other electrode. Suspended from the cover is an electrode plate which extends into the tank through an opening in the neutral member and is surrounded by a diaphragm depending from the latter.—W. E. F. P.

Electrolytic gas-generator. I. H. Levin, Newark, N.J., U.S. Pat. 1,219,966, Mar. 20, 1917. Date of appl. Nov. 18, 1916.

THE electrode compartment of the generator has a gas outlet which is sealed with water, and through which water is supplied to the compartment, from a chamber above. The water chamber is provided with a gas outlet and a water supply conduit.—W. E. F. P.

XII.—FATS; OILS; WAXES.

Fatty acids; Action of aromatic amines on —. [Analysis of fats.] E. de Conno. Gazz. Chim. Ital., 1917, 47, 1, 93—132.

GLYCERIDES are hydrolysed when heated in a sealed tube at 230° C. with an aromatic amine, such as aniline, and yield the corresponding amides of the liberated fatty acids. The decomposition is not quantitative, but the resulting anilides contain a portion of all the fatty acids in the relative proportions in which they were present in the fat, so that the method may be used for the qualitative and possibly for the quantitative analysis of fats. The anilides of the fatty acids prepared distilled under reduced pressure (10 mm.) without alteration and at intervals of about 10° C. for the different members of a series. They can thus be separated by fractional distillation, and when they are heated with strong hydrochloric acid in a sealed tube for 3 hours at 150° C. the corresponding fatty acid is liberated. They are insoluble in water, sparingly soluble in petroleum spirit, readily soluble in acetone and hot acetic acid, and very soluble in ether, chloroform, benzene, and toluene. They are best crystallised from

hot alcohol or methyl alcohol. The anilides of the saturated fatty acids melt at temperatures from 81.5° to 132° C., and those of the unsaturated fatty acids at 41° to 114° C., with the exception of linolenic anilide, which is liquid. The *p*-phenylenediamides of the saturated fatty acids from myristic to arachidic acid and of the unsaturated fatty acids (oleic, erucic, and linolenic acids) are insoluble in all the above-mentioned solvents, but can be purified by recrystallisation from hot amyl alcohol. They melt at the following temperatures:—From myristic acid, 162.5°; palmitic acid, 181.5°; stearic acid, 179.5°; arachidic acid, 139.8°; oleic acid, 158.7°; and erucic acid, 151° C. The other amides prepared include those of *p*-toluidine, *m*-dimethylaniline, *p*-hydroxyaniline, *p*-methoxyaniline, *p*-ethoxyaniline, α -naphthylamine, and β -naphthylamine. When fatty acids are heated in a sealed tube with an equimolecular proportion of the aromatic amine, they yield from 85 to 87% of the corresponding fatty acid amide.—C. A. M.

Resistance of an oil to emulsification. Herschel. See II A.

Copra-drying apparatus. J. D. McCord, Manila, Philippine Islands. U.S. Pat. 1,219,016, Mar. 13, 1917. Date of appl. Mar. 20, 1916.

THE copra is dried in a chamber surrounded by a heat-flue communicating with a heater, whilst an air-flue is interposed between the heat-flue and the chamber, and means are provided for circulating heated air through the air flue and into the chamber.—C. A. M.

Fats and oils; Process for decomposition of —. B. E. Reuter, Assignor to Reuter Process Co., Chicago, Ill. U.S. Pat. 1,219,485, Mar. 20, 1917. Date of appl. May 20, 1912.

FATS or oils are mixed first with water, and then with sulphuric acid (0.03 to 1%) and a quantity of a catalyst (0.1 to 0.4%) insufficient to effect complete decomposition of the fats, the mixture is boiled for 12 to 18 hours with constant agitation, and the resulting fatty acids are bleached.—C. A. M.

Fats and fatty substances; Process for emulsifying —. J. Schlieck, Hamburg, Germany. U.S. Pat. 1,220,010, Mar. 20, 1917. Date of appl. Aug. 12, 1916.

A FAT poor in cholesterol and melting between about 26° and 36° C., is thoroughly mixed with skim-milk or other liquid containing albumin, and about 0.1 to 0.4% of cholesterol.—C. A. M.

Soft soaps; Manufacture of —. Robinson Bros., Ltd., and H. Swithenbank, West Bromwich. Eng. Pat. 104,409, Mar. 28, 1916. (Appl. No. 4560 of 1916.)

MARINE animal oils are sulphonated with strong sulphuric acid, the product treated with water, and the aqueous layer containing the glycerol separated from the sulphonated oil. The latter is then saponified with caustic soda, and sufficient water is added to obtain a clear, transparent, soft soap, which is free from fishy odour. The consistency of the soap may be varied by varying the temperature at which sulphonation is effected. Rosin may be added prior to saponification and sodium silicate after the saponification.—C. A. M.

Fats and fatty substances; Process for emulsifying —. J. Seidnick, Hamburg, Germany. Eng. Pat. 101,933, Mar. 27, 1916. (Appl. No. 4506 of 1916.)

SEE U.S. Pat. 1,220,610 of 1917; preceding.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Litharge-glycerol cement; Selling of —. H. E. Merwin. J. Ind. Eng. Chem., 1917, 9, 390.

LITHARGE which had been passed through a 200-mesh sieve was mixed with a large excess of glycerol on a microscope slide under a cover glass, and the mixture examined under the microscope. The formation of a crystalline compound was observed after about 1 hour; and after 24 hours, the grains of litharge were bound together by crystalline aggregates of radiating fibres. Grains kept at 80°C. for an hour were also firmly cemented. Similar crystals were obtained when glycerol diluted with 5 to 10% of water or alcohol was heated to boiling-point and agitated with litharge, but the crystals were less closely aggregated. The best specimen thus prepared contained about 10% of unattacked litharge and 90% of crystals. The crystals contained 70.8% of lead oxide, corresponding with 5% of residual PbO and 95% of the compound $C_3H_5O_2.PbO$. After standing for several days in contact with glycerol the centres of the litharge grains were still unattacked, and probably coarser grains would remain so indefinitely. This cement is employed for lining the digesters used in the manufacture of sulphite pulp.—C. A. M.

Phenol resin compounds; Printing plates from —. L. V. Redman, A. J. Weith, and F. P. Brock. J. Ind. Eng. Chem., 1917, 9, 388—390.

THE original zinc etching is placed on the top of a sheet of a plastic phenol resin compound which has been previously heated until soft and pliable, and both are gradually pressed in a hot press up to a pressure of about 2000 lb. per sq. in. The press heads are prevented from coming together by means of controlling bars, whilst the plastic compound is allowed to flow out around the edges. After hardening for a few minutes the mould is removed, and may be used immediately for the production of positive plates in the same way from fresh plastic sheets. A layer of oiled paper, metal foil, or talc dust, etc., is used to prevent the cast from sticking to the mould, and this improves the printing properties of the plate as compared with the original zinc etching.—C. A. M.

PATENTS.

Resin and turpentine; Process and apparatus for making —. G. Pissimis and J. Rigopoulos, Schenectady, N.Y., Assignors to P. Chiboucas, Albany, N.Y. U.S. Pat. 1,219,998, Mar. 20, 1917. Date of appl. July 14, 1916.

CRUDE turpentine is heated and agitated in a tank by passing steam through a chamber under the tank and also into the liquid. Impurities are withdrawn from the bottom of the tank and vapour from the top. Liquid is drawn from the tank at different levels through a filter to a second tank. The liquid is forced from this tank to an auxiliary tank by steam pressure on the surface of the liquid in the filter. The auxiliary tank is heated and the vapour passed through condensers and collected. The resin is collected from the bottom of the second tank.—W. F. F.

Manufacture of picric acid and other nitrophenols from certain gums or gum-resins. Eng. Pat. 101,352. See III.

Treatment of certain gums or gum-resins for the manufacture of colouring matters or dyes. Eng. Pat. 101,353. See IV.

Rubber exports from Brazil. India-Rubber J., Apr. 14, 1917.

EXPORTS of rubber of all kinds from Brazil in 1916 amounted to 31,195 tons, against 35,165 tons in 1915 and 33,531 tons in 1914. The value of the exports increased from £7,010,000 in 1915 to £7,496,000 in 1916. As usual the greater part of the quantity exported was sent to the United States and the United Kingdom, the respective figures for 1916 being 19,965 and 10,379 tons.

Rubber hose for use on aeroplanes. P. A. Houseman. J. Ind. Eng. Chem., 1917, 9, 356—358.

THE following tests are suggested for ascertaining the suitability of rubber hose for conveying petrol from the tank to the engine on aeroplanes. *Flexibility.* The tube when bent into a circle, the diameter of which varies from 4 in. for tubes of 0.5 in. internal diameter to 18 in. for 1.5 in. tubing, should not decrease in diameter at any point by more than 10% of the original diameter. *Immersion in petrol.* The tubing is immersed in petrol (sp. gr. 0.720) for 200 hours, or boiled in petrol under a reflux condenser for 1 hour and then left in cold petrol for 24 hours. Under this treatment the diameter of the tube should not decrease by more than 25%. The adhesion of the rubber to the canvas should remain good, and the "nerve" of the rubber should not be seriously affected. *Permeability to petrol.* A piece of the tubing 12 in. long, is fixed vertically, the lower end is plugged, and a piece of glass tubing fitted in the upper end. The tubing and glass tube are filled with petrol and the level of the petrol is maintained at 9 to 12 in. above the top of the tubing. After 48 hours, the amount of petrol passing through the walls of the tubing during the succeeding 24 hours should not exceed 100 c.c. per sq. ft. of internal surface. *Heat test.* The rubber must remain elastic after the tubing has been heated at 132°C. for 2 hrs. A freezing test (in carbon dioxide snow) does not give any useful information. The rubber portion of the tubing should contain at least 40% of rubber, the layer of rubber between each turn of the canvas should be at least twice as thick as the canvas itself, and the inner layer of rubber should be seamless. Tubing more than 6 months old should not be used. Rubber hose for use with oil must withstand immersion in castor oil at 100°C. for 8 hours without serious injury and not increase in weight by more than 5% during this treatment.—W. P. S.

PATENTS.

Rubber composition and process of making the same. M. F. Coughlin, Boston, Mass., Assignor to American Gum Products Co., Covington, Va. U.S. Pat. 1,217,157, Feb. 27, 1917. Date of appl. Oct. 21, 1916.

RUBBER is incorporated with dry sulphite waste lye solids, blown petroleum, and asphalt, with or without other loading materials.—W. H. C.

Indiarubber; Roller apparatus for use in the treatment of —. J. Hodgins, Cork, Ireland. Eng. Pat. 104,914, Mar. 22, 1916. (Appl. No. 4215 of 1916.)

Tarwad [*turwah* or *cassia*] bark as a tanning agent. D. B. Limaye, Bull. No. 1, Ranade Industrial and Economic Inst., Poona, India, 1916, 18 pages.

TARWAD bark, the product of the perennial shrub, *Cassia auriculata*, is used very considerably in the tanning industry of Bombay and district, but has not up to the present been used in Europe. Samples of the bark were obtained from various districts of Central India and the Deccan, and showed from 15.2% to 19.6% tannin. The results showed that plants three years old contain distinctly more tannin (usually about 2%) than do plants only one year old. Commercial samples obtained in the ordinary markets proved to contain 15.5% to 18.7% tannin. The author considers that an increased production of the bark will cause an increase in price, unless the bark is cultivated as a crop. The low tannin content will not allow of profitable export, but a concentrated extract could be manufactured in India.—F. C. T.

Tannins; Detection and differentiation of vegetable and synthetic —. R. Laufmann. Chem. Zeit., 1917, 41, 273—275 and 286—288. (See also this J., 1916, 551.)

A GENERAL scheme is given for the identification of the various vegetable tannins by the ordinary methods, including the ammonium molybdate test. Reactions are also described as follows for the detection and distinction in leather of sulphite-cellulose extract and artificial tannins of the Neradol class. Finely divided leather is allowed to stand overnight in ten times its weight of 2% caustic soda solution. The solution is then filtered, slightly acidified with hydrochloric acid, filtered again, and diluted so as to contain 0.6% organic matter. It is then tested by the aniline test or by cinchonine sulphate. A negative result shows the absence of both sulphite-cellulose and Neradol. A positive result indicates sulphite-cellulose if Neradol is subsequently proved to be absent by special tests. (1) 3—4 drops of an ice-cooled diazotised solution of *p*-aminophenol are added to a well-cooled mixture of 5 c.c. of alcohol and 5 c.c. of the above solution. A blue colour indicates Neradol. If the result is negative, the reaction mixture is extracted with ether, the ethereal layer removed and poured on to water to which caustic soda solution is then slowly added. A deep blue-grey colour at the water-ether surface indicates Neradol. (2) 5 c.c. of the leather extract is rendered alkaline with caustic soda after the addition of one drop of a solution of dimethyl-*p*-phenylenediamine hydrochloride; 1—2 drops of 5% potassium ferricyanide solution are then added. In the presence of Neradol a blue colour develops. (3) The leather extract is treated with a solution of diazotised *p*-nitroaniline, the precipitate filtered off, and the filtrate rendered alkaline with caustic soda. A deep blood-red colour indicates Neradol. These tests (1 to 3) need some modification if the Neradol is a naphthalene product. According to Moeller, sulphite-cellulose and Neradol can be distinguished as follows:—The solution, as concentrated as possible, is mixed thoroughly with absolute alcohol and filtered. The filtrate is evaporated to remove alcohol, diluted, and treated with sulphuric acid to precipitate phlobaphenes and humic substances. The solution is filtered again and neutralised with sodium carbonate. A fair excess of 2½% solution of pure aniline hydrochloride is then added, which causes a precipitate in the presence of Neradol. The precipitate first obtained by mixing the original aqueous solution with alcohol, as above, is tested by the Procter-Hirst method for sulphite-cellulose.—F. C. T.

Hide powder; Adsorption of chromium oxide by —. A. W. Davison. J. Phys. Chem., 1917, 21, 190—197.

QUANTITIES of hide powder were shaken with basic chromium sulphate solutions, under conditions absolutely uniform except for the concentration of chromium sulphate. Preliminary experiments showed that four hours' shaking was sufficient to allow of the attainment of equilibrium between the solution and the tanned hide powder. After shaking, the solution and the chromed hide powder were both analysed to determine the concentration of chromium in each case. These values when plotted as ordinates and abscissae respectively, gave a perfectly smooth curve of the type well known in cases of adsorption. The author's results thus favour the physical as against the chemical theory of tanning.—F. C. T.

Glue for use on aeroplanes. P. A. Houseman. J. Ind. Eng. Chem., 1917, 9, 359—360.

THE following arbitrary method is suggested for testing the quality of glue used for joining together the laminae of aeroplane propellers. Pieces of straight-grained walnut wood, each 9 in. by 2 in. by ½ in., are dried at 36° C. for 24 hours, then roughened by a tooth-plane, and two of the pieces are glued together so that their ends overlap by 2 in.; the area of the glued surface is therefore 4 sq. in. The glue is prepared by soaking the pieces for about 18 hours in water, then heating the mixture to 60° C. and applying it at this temperature; usually, 1 part of glue to 2 parts by weight of water gives a suitable concentration. The joint is clamped under moderate pressure for 48 hours and tested after a further 24 hours, the tests, in duplicate, being made as follows:—*Regular test*. The joints are pulled apart in a testing machine and the breaking strain per sq. in. of glued surface is recorded. *Heat test*. The joints are heated at 45° C. for 2 days and then pulled apart, and the breaking strain recorded. *Immersion test*. The joints are completely immersed in water at 20° C. for 12 hours and then pulled apart. Results of from 450 to over 600 lb. per sq. in. of glued surface are found in the regular test, and about the same figures in the heat test, whilst the immersion test results are sometimes lower and sometimes higher than the regular test results. The addition of a small proportion (5%) of phenol to the glue solution increases the strength of the joint; addition of ammonia does not affect the regular test results but raises the heat and immersion test figures. A Swiss casein glue, of the type used on German aircraft, and consisting of about 66% of casein, 23% of mineral matter (sodium salts, silica, lime and alumina), and 1% of petroleum, gave a particularly high result in the immersion test.—W. P. S.

Fish-gelatin; Hydrolysis of —. Y. Okuda. J. Coll. Agric., Tokyo, 1916, 5, 355—363.

To ascertain if fish-gelatin differed in chemical composition from ordinary bone-gelatin, material derived from the skin of a shark was hydrolysed with hydrochloric acid, baryta, and sulphuric acid, and the products investigated. The total nitrogen and its distribution were found to be practically the same for both sorts; but the fish-gelatin gave rather more monoamino-acid, and much more glycocoll, alanine, leucine, phenylalanine, glutamic and aspartic acids than the bone-gelatin. The proline and serine contents of the fish-gelatin found by the ester method were low, probably the results of experimental errors. The diamino-acids were present in about equal quantities in the two gelatins.—E. H. T.

PATENT.

Keratin bodies; Process of treating — C. G. Stebbins and A. Gelow, Assignors to The Warren Featherbone Co., Three Oaks, Mich. U.S. Pat. 1,219,787, Mar. 20, 1917. Date of appl., Apr. 12, 1915.

KERATIN bodies are shredded, and the filaments heated to a sufficient temperature to inhibit bacterial action and expel all moisture, and then immersed in an elastic, waterproofing medium. Absorbent keratin substances may be sized prior to the heating.—C. A. M.

XVI.—SOILS; FERTILISERS.

Humogen; Report on — E. J. Russell. J. Board Agric., 1917, 24, 11—20.

EXPERIMENTS made with "humogen," or "bacterised peat" (see this J., 1913, 878; 1915, 871) on plants in pots, at Kew, and at Wisley, having given remarkable results, a series of investigations was carried out at Rothamsted to ascertain if the product possesses a similar value in agriculture. The humogen used in the experiments was obtained from two different sources, and contained 0.57 and 0.13% N (1.29 and 1.32% in the dry matter) respectively. It is stated by Prof. Bottomley that there was a serious error in the manufacture of the product, owing to the use of an excessive amount of alkali, resulting in the production of a chemically treated peat containing excess of soda, and not a properly "bacterised" peat. Field experiments with mangolds gave entirely negative results, the humogen showing no special fertilising effect; in the only cases where increases were produced they were no greater than were obtained with untreated peat. Mustard grown in pots showed similar results to the trials with mangolds, and peas gave entirely negative results. In experiments with barley in water cultures, the plants receiving humogen were darker in colour than the others, but the difference in weight was less than 5%, and no significance is attached to this result. Experiments carried out at the same time at the Harper Adams Agricultural College, with wheat and with mangolds, gave similar results; with wheat, in fact, the crop was somewhat depressed by humogen, whilst in the case of mangolds some increases were observed, but the fertilising action is believed to be no greater than that due to the moisture-retaining properties of peat. It is concluded that the agricultural value of humogen is no greater than that of any other organic manure with the same nitrogen content. The claims made for it in the press and elsewhere are considered to have no substantiation and its present price (£5 per ton) is excessive.

Soils of south New Zealand; Lime requirements of — L. J. Wild. J. Agric. Sci., 1917, 8, 151—177.

THE Hutchinson-MacLennan method (this J., 1915, 365) gave results superior to those from ordinary analytical methods, provided it was carried out under uniform conditions. The results, however, always showed a higher lime requirement than that required by field practice; hence a correcting factor should be used; that for the soils of Canterbury Plains is about 0.10%.—E. H. T.

Calcium cyanamide; Some conditions affecting the value of — as a manure. T. D. Moss crop. J. Agric. Sci., 1917, 8, 175—181.

LETTUCE seeds were germinated on tiles under water-sealed bell-jars, in each of which was

placed a crucible containing 4 grms. of calcium cyanamide mixed with water, or the same mixed with damp soil or with soil water; in no case did the fertiliser itself come in contact with the seeds. The cotyledons of the seeds were soon blackened and disorganised, and the air and water became strongly alkaline; on germinating fresh seeds in presence of ammonia vapour the effect upon them was exactly the same. Barley and turnip seeds were found to withstand the influence of 1 gm. of calcium cyanamide under the same conditions. A quantitative examination of the gases evolved by the action of 100 c.c. of water on 1—5 grms. of calcium cyanamide during one week gave: carbon dioxide 0.0237%, ammonia 0.43%. When soil was used in addition to water 2.86% of ammonia was obtained. For seeds with a thin testa and for non-oily seeds, the calcium cyanamide should be applied a week before sowing.—E. H. T.

Superphosphates; Use of — in agriculture. N. A. Barbieri. Gazz. Chim. Ital., 1917, 47, 1, 38—51.

ANALYSES described show that the whole of the phosphorus in plants and in animals is in the form of phosphoric acid combined with alkalis, alkaline-earth bases, and some other mineral bases. After elimination of all the phosphates from cereals and leguminous plants by extraction with water, ether, and alcohol, the residue contained no trace of phosphorus. Plants do not contain mono-calcium or dicalcium phosphates, the whole of the phosphoric acid being in the form of tricalcium phosphate. Germination experiments with the seeds of the vetch and wheat under various conditions showed that the plants do not absorb monocalcium or dicalcium phosphate, but that these salts check the germination of the seeds and growth of the plants. Cereals and leguminous plants from soil manured with superphosphates contained less phosphorus than the plants from adjacent soil which had not been treated with superphosphates. Moreover, superphosphates destroy seeds with which they come in contact. The general conclusion is drawn that if plants require mineral fertilisers the substances used should be those which the plants contain.—C. A. M.

Phosphoric acid [in fertilisers]; The volumetric or Pemberton method for determining — with some experiments showing the influence of temperature and the sulphuric acid radical on the results. P. McG. Shuey. J. Ind. Eng. Chem., 1917, 9, 367—370.

THIS method was found to be trustworthy. The presence of sulphuric acid caused the results obtained to be too high by about 1%, but when the sulphuric acid was removed by the addition of barium chloride the results were correct. The temperature at which the phosphoric acid was precipitated with molybdic acid reagent had a considerable effect; the most concordant results were obtained by precipitating at 30° to 40° C. It is recommended that a control determination, using a standard phosphate rock, should be made when acid phosphates (superphosphates) are being analysed, this precaution applying particularly when it is necessary to destroy organic matter in the sample by means of sulphuric and nitric acids; the sample and control should be treated exactly alike. (See also Fairchild, this J., 1912, 350.) —W. P. S.

Practicability of the recovery of nitrogen in sewage sludge. Copeland. See XIXb.

XVII.—SUGARS; STARCHES; GUMS.

Galactobioses; Biochemical synthesis of two — by means of emulsin. E. Bourquelot and A. Aubry. *Comptes rend.*, 1917, **164**, 443—445, 521—523.

THE product of the prolonged action of emulsin on concentrated solutions of galactose (this J., 1916, 867) has yielded two crystalline galactobioses by successive treatments with alcohol. They crystallise from methyl alcohol, are only slightly sweet, and have cupric-reducing powers about half that of galactose. These two galactobioses, which have $[\alpha]_D = +35.05^\circ$ and $+33.05^\circ$, probably correspond with the two glucobioses hydrolysable by emulsin, *viz.*, gentiobiose and cellobiose, which have $[\alpha]_D = +10^\circ$ and $+33.3^\circ$ respectively.—J. H. L.

PATENT.

Sugar-separating machine. L. M. Clairain and O. J. Suares, New Orleans, La. U.S. Pat. 1,217,705, Feb. 27, 1917. Date of appl. June 5, 1915.

A LONG trough has, near one end, an opening in the bottom, covered by a screen, below which is a funnel-shaped collector connected with an exhausting device. Mounted longitudinally within the trough is an endless conveyor, carrying at intervals transverse scraping lugs which engage the bottom of the trough to spread the material thereon and carry it over the screen. Means are provided for feeding syrup into the trough at the end near the screen and for discharging sugar at the other end.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Barley extract; Determination of —. R. Kutscha. *Woch. Brau.*, 1916, **33**, 233—235, 245—247, 252—254, 259—261, 270—272, 277—279, 285—286, 291—293. (See also Seibriger, this J., 1910, 893; 1914, 97.)

THE numerous methods which have been proposed for the determination of barley extract are described. The author has had extensive experience with Pawlowski's and Seibriger's, and usually found good agreement (*i.e.* within 1%) between them and several others, but differences in the quality of barleys do not always affect the results of different methods to the same extent. The relation between the percentage extract yield of barley and that of the corresponding malt, both being calculated on dry substance, depends on the type of malt produced; in the case of pale, low-cured malts the two values are often practically identical, but more highly-cured malts give results 1 or 2% lower. For given malting conditions, the relation between barley and malt extracts is influenced also by the quality of barleys, and may vary with the latter from year to year. For example, the author found that with barleys of 1913 and 1914, Pawlowski's and Seibriger's methods gave results usually about 1% above the laboratory yields of extract obtained from the corresponding malts (pale Pilsener type); with barleys of 1915, which were of rather poor quality, the results were on the average about 2% higher than the extract yields of the malts estimated by the official method of the Bonn convention. With these 1915 barleys the method recently proposed by Heintz (*Woch. Brau.*, 1916, **33**, 65, 268, 305) gave results in good agreement with those for the malts. The nitrogen-content of barleys, taken alone or in conjunction with the 1000-corn weight, does not afford a basis for computing the extract yield either of the barley

or of the corresponding malt (*cp.* Lintner, this J., 1911, 1080). The author found differences of 5% between the extract yields of barleys of equal nitrogen-content.—J. H. L.

[*Brewing; Pre-mashing and the protein-rest* (in —)]. F. Lehmann. *Woch. Brau.*, 1916, **33**, 281—283.

THE author agrees with Windisch (this J., 1916, 1170) as to the advantages of pre-mashing and the protein-rest in working with short-grown malts. To obtain the best results from the protein-rest a high acidity is necessary, to promote proteolysis. Phosphoric acid and acid phosphates appear to exert a specific influence on wort proteins, tending to prevent the formation of protein-turbidity on heating or on chilling. A solution of acid phosphates, used for sprinkling green malt in the course of germination, improves the quality of the malt produced. The results obtained with pre-mashing and the protein-rest depend on the character of the brewing water, and magnesium salts in the latter are particularly injurious, possibly because they may precipitate phosphoric acid as dimagnesium phosphate. This precipitation is hindered by a high lactic acidity such as may be produced by pre-mashing for a longer time or at a higher temperature. A portion only of the total malt need be pre-mashed and sufficient acid developed in this portion for the whole mash. This reduces the danger arising from the presence of the husk during pre-mashing (*see loc. cit.*), and is simpler than screening the whole grist to remove the husk portions.—J. H. L.

Alcoholic fermentation in presence of alkalis; Course of —. I. Cell-free fermentation in alkaline solutions. C. Neuberg and E. Färber. *Biochem. Zeits.*, 1916, **78**, 238—263.

THE fermentation of 5% sugar solutions by yeast maceration juice was found to proceed to completion in presence of 0.1—0.2 gm.-mol. of sodium or potassium carbonate, potassium metaborate, or tripotassium phosphate, or 0.02 gm.-mol. of sodium or potassium sulphite, per litre, when the alkaline substance was added before fermentation had commenced; but when the addition was made after fermentation had well started, about twice the above amounts did not prevent complete fermentation of the sugar. The authors conclude that alkalis have a special inhibitive influence on the inception of the first stages of fermentation which precede the evolution of carbon dioxide. Fermentations which had been arrested by adding large amounts of alkali were resumed on addition of free phosphoric or lactic acid, but not on addition of soluble phosphates or hexose-phosphates.—J. H. L.

Alcohol; Immersion refractometer in the determination of small amounts of — in hopped beverages. A. Fonyo. U.S. Master Brewers' Assoc. Amer. Brewers' J., 1917, **41**, 112—113.

USING the methods and tables of the Association of Official Agricultural Chemists (U.S.A.), the author carried out determinations of alcohol with unhopped wort, and with hopped worts containing up to 0.5% of added alcohol, determining the sp. gr. of the distillates and also their refractometer readings in a Zeiss-Pulfrich instrument at 20°C. (*cp.* this J., Ackermann and Steinmann, 1905, 563; Barnard, 1907, 707). The pyknometric results showed no alcohol in the unhopped wort, but the hopped wort containing no alcohol showed 0.01%, and the results for the hopped worts containing alcohol were all high by about the same amount. This is attributed to traces of volatile hop constituents not removed during ordinary

wort boiling, which are carried over during distillation and reduce the sp. gr. of the distillate slightly. The refractometric results were accurate, subject to the qualification that the limit of sensitiveness was about 0.08%, this amount being indicated alike in the distillates from pure water and from hopped wort containing 0.05% of alcohol. In using the refractometer, an error of 1° C. in the temperature of the liquid observed, was found to produce an error of about 0.2% in its apparent alcohol-content. For the concentration of alcohol from worts containing only small amounts, Bacon's method (see this J., 1912, 42) was found very satisfactory.—J. H. L.

Biochemical synthesis of a second galactobiose. Bourquelot and Aubry. See XVII.

PATENTS.

Beer: Compounds for preserving —. G. Rottenkolber, Cornwall, Ont., Canada. U.S. Pat. 1,217,641, Feb. 27, 1917. Date of appl. July 21, 1916.

THE products claimed consist of "potassium pyrosulphite," tartaric acid, and sodium bicarbonate, e.g., in the proportions 13 : 2 : 1.—J. H. L.

Beverage: Carbonated — and method of making same. C. G. Kummerlander, Washington, D.C. U.S. Pat. 1,218,190, Mar. 6, 1917. Date of appl. Dec. 22, 1916.

SOLUBLE albuminoid matter is treated with a proteolytic enzyme, and after removal of unhydrolysed protein the product is added to a carbonated beverage at any stage of manufacture. Egg albumin in water may be hydrolysed by pepsin, diluted, boiled with hops, chilled, filtered, and employed in the preparation of non-alcoholic carbonated beverages.—J. H. L.

XIXa.—FOODS.

Condensed milk, dried milk, and malted milk. U.S. Dept. Agr., Food Inspection Decision 170, Mar. 31, 1917.

THE following definitions and standards for sweetened condensed milk, condensed skimmed milk, sweetened condensed skimmed milk, dried milk, dried skimmed milk, and malted milk were adopted by the Joint Committee on Definitions and Standards, August 7th, 1916, and were approved by the Association of American Dairy, Food, and Drug Officials, August 10th, 1916, and by the Association of Official Agricultural Chemists, November 22nd, 1916:—*Sweetened condensed milk, sweetened evaporated milk, sweetened concentrated milk*, is the product resulting from the evaporation of a considerable portion of the water from the whole, fresh, clean, lacteal secretion obtained by the complete milking of one or more healthy cows, properly fed and kept, excluding that obtained within fifteen days before and ten days after calving, to which sugar (sucrose) has been added. It contains not less than 28.0% of total milk solids, and not less than 8.0% of milk fat (see also this J., 1915, 416). *Condensed skimmed milk, evaporated skimmed milk, concentrated skimmed milk*, is the product resulting from the evaporation of a considerable portion of the water from skimmed milk, and contains not less than 20.0% of milk solids. *Sweetened condensed skimmed milk, sweetened evaporated skimmed milk, sweetened concentrated skimmed milk*, is the product resulting from the evaporation of a considerable portion of the water from skimmed milk to which sugar (sucrose) has been added. It contains not less than 28.0% of milk solids. *Dried milk* is the product resulting from the removal of

water from milk, and contains not less than 26.0% of milk fat, and not more than 5.0% of moisture. *Dried skimmed milk* is the product resulting from the removal of water from skimmed milk and contains not more than 5.0% of moisture. *Malted milk* is the product made by combining whole milk with the liquid separated from a mash of ground barley malt and wheat flour, with or without the addition of sodium chloride, sodium bicarbonate, and potassium bicarbonate in such a manner as to secure the full enzymic action of the malt extract and by removing water. The resulting product contains not less than 7.5% of butter fat and not more than 3.5% of moisture.

Milk: Study of certain ferments [enzymes] with a view to determining a method for the differentiation of pasteurised milk from raw —. I. Reductases. R. E. Lee and M. G. Mellon. J. Ind. Eng. Chem., 1917, 9, 360—367.

AN outline is given of the classification, distribution, and reactions of certain enzymes and a description of experimental work concerning the source, nature, and action of reductase in its relation to methods which have been proposed for the differentiation of pasteurised milk from raw milk. It was found that the Methylene Blue in Schardinger's reagent (a solution containing Methylene Blue and formaldehyde) was not decolorised by normal fresh milk in less than 20 mins. unless the milk contained more than 1,000,000 bacteria per c.c., or by recently pasteurised milk. The reagent was decolorised by milk which had been allowed to "age" for 24 to 48 hours. Pasteurisation increased the time required for decolorisation. Generally, there was no parallelism between the number of bacteria present in a milk and the time required for the decolorisation of the reagent, but a certain relationship seemed to exist in a given sample of milk indicating that reductase is of bacterial origin, and that not all the bacteria existing in milk produce this enzyme. Formaldehyde appeared to retard the action of the reductase or even to destroy it.

—W. P. S.

Lecithin in egg-yolk: Non-existence of free or combined —. N. A. Barbieri. Gazz. Chim. Ital., 1917, 47, I, 1—37.

EXPERIMENTS described in detail show that fats may be quantitatively separated in a pure state from egg-yolk by extraction with neutral solvents. On saponification they yield only glycerol and fatty acids. These fats are able to keep in solution or suspension nitrogenous substances, colouring matters, and phosphates, and these substances can be separated by dialysis, by hydrolysis with a very weak (0.1%) acid, or by repeatedly washing the alcoholic solution with water. The residual fats remain completely unaltered. The whole of the phosphorus in egg-yolk is in the state of phosphoric acid in combination with alkali bases (potassium, sodium), alkaline-earth bases (calcium), and magnesium. Glycerophosphoric acid cannot be separated by means of neutral solvents, but only by saponification. On decomposing the soap with acids the glycerol and the phosphoric acid derived from the phosphates pass into the aqueous solution. No trace of choline is present in egg-yolk. The so-called choline constituent of the alleged lecithin is a product of the hydrolysis of orocromin or a putrefaction product. In view of these facts the conclusion is drawn that lecithin (containing glycerol, phosphoric acid, and stearic acid) is not present in egg-yolk.—C. A. M.

Protein of swede turnips: Hydrolysis of the soluble —. G. Williams. J. Agric. Sci., 1917, 8, 182—215.

THE expressed juice of healthy swedes was filtered

and heated to 90° C. for half an hour. The precipitated protein after repeated washings with hot water, alcohol, and ether, weighed 0.15 gm. per 100 c.c. of juice, and analysis gave N=14.09% (or 15.63% ash-free), H_2O = 1.81%, and ash 8.60%. The ash contained calcium and phosphoric acid corresponding to 26.33% of calcium phosphate, and the sulphur-content of the protein—mostly present in the ash—was 4.2%. On hydrolysis with dilute sulphuric acid the content of diamino-acids was found to be: arginine 3.12% of the protein, histidine 3.04%, lysine 4.35%. After hydrolysing with concentrated hydrochloric acid, 3.18% of glutamic acid and 6.98% of aspartic acid were found by Foreman's method (J. Agric. Sci., 1911, 4, 431); there was also 0.27% of glycine, 3.58% of alanine, 9.95% of valine, 9.01% of leucine and isoleucine, 4.47% of phenylalanine, 4.17% of proline, 2.92% of tyrosine, 1.21% of ammonia, and 4.74% of humin bodies; tryptophan and cystine were also present. The Levene and Van Slyke method of separating alanine and valine (J. Biol. Chem., 1912, 12, 285), the picrate method of separating glycine and alanine, and the separation of valine and the leucines by the lead method (this J., 1909, 1100) were all found to work well, and if pure chemicals are used the first-named method can be used for preparing pure alanine and pure valine. This physiologically-active protein differs from the vegetable proteins already studied by containing much more glutamic acid than aspartic acid; further, the valine content is unusually high and the ammonia content low. As cereals have a high glutamic acid content, the combination of swedes with cereals for feeding stuffs is recommended.—E. H. T.

Pectic substances of plants. S. B. Schryver and D. Haynes. Biochem. J., 1916, 10, 539—547. Analyst, 1916, 42, 141.

PECTINOGEN is separated from plants, fruits, and vegetables by extracting the residue remaining after the expression of the juices with warm 0.5% ammonium oxalate solution, followed by concentration of the extract to small bulk, and precipitation with acidified alcohol. The gelatinous precipitate so obtained is washed with alcohol and finally air dried, when it yields a granular white powder. The yield from 100 kilos. of turnips is 355 grms. The pectinogen so obtained has an acidic character, and if kept in alkaline solution for a short time readily undergoes conversion into pectin, which is also of acidic character, soluble in alkalis, and precipitated from its alkaline solution by acids as a gel insoluble in water. Analyses of pectins agree with the formula $C_{17}H_{24}O_{16}$. On distillation with hydrochloric acid, pectinogen yields fufural in such quantity as to indicate that one pentose group is present in each complex of 17 carbon atoms. Pectin would appear to be not a carbohydrate but an acid.—J. N. P.

PATENTS.

Milk and cream; Process of manufacturing products from —. C. E. Gray. Eureka, Cal. U.S. Pat. 1,219,291, Mar. 13, 1917. Date of appl., Dec. 13, 1910.

MILK and cream are heated under diminished

pressure, whereby the incorporated oxygen and some aqueous vapour are removed. An amount of water equivalent to the aqueous vapour is added to the product, which is then cooled and agitated under oxygen-free conditions.—J. H. J.

Process for emulsifying fats and fatty substances. U.S. Pat. 1,220,010. See XII.

XIXB.—WATER PURIFICATION; SANITATION.

Water; Determination of the quantity of hypochlorite required to sterilise —. Massy. J. Pharm. Chim., 1917, 15, 209—213.

THE criterion of purification being the total destruction of *B. coli*, the most satisfactory means of determining the quantity of hypochlorite required for the treatment of an impure water would be the bacteriological examination of the water after the addition of varying quantities of the hypochlorite solution, but in the case of water required for the use of armies in the field, the time required for the examination precludes its adoption. A rapid method which serves practically the same purpose consists in treating small quantities of the water with increasing amounts of hypochlorite solution and then testing for the presence of free chlorine by the potassium iodide-starch reaction. As described by Gascard and Guy-Laroche (Presse Med., Aug. 5, 1915), several similar quantities of the water are treated with successively increasing volumes of the hypochlorite solution, and, after 20 mins., potassium iodide and starch are added: the test containing the largest quantity of hypochlorite without exhibiting a blue coloration is the one containing the required amount of hypochlorite. The British Army uses the same method with the modification that the potassium iodide and starch are added immediately after the hypochlorite and the observation is made after the lapse of 30 mins. The two methods yield practically the same results. The author has attempted to use sodium sulphindigotate as indicator in place of iodide and starch, but the results obtained were unsatisfactory.—W. P. S.

Nitrogen in sewage sludge; Practicability of the recovery of —. W. R. Copeland. J. Ind. Eng. Chem., 1917, 9, 374—376.

THE sludge hitherto obtained by the best known methods of sewage treatment has contained from 1.2 to 3.0% of nitrogen, the loss, as compared with the raw sewage, being attributable to removal of nitrogen in colloidal matter in suspension in the effluent, and in the case of chemical precipitation works, to the formation of ammonia by the added lime. It is also estimated that from 10 to 60% of the solids deposited in septic tanks is converted into soluble or gaseous form. In the so-called "activated sludge" process (see this J., 1917, 264) recently tried in America and England, the colloidal and suspended matters are collected in the sludge, and if over-aeration be avoided the solids are not liquefied to the same extent as in septic tanks and therefore the nitrogen does not escape. For example, in the case of Milwaukee City sewage the digested sludge accumulates in the Imhoff tanks at the rate of 1 to 10 cub. yds. per 1,000,000 galls. of sewage treated, whereas by the "activated sludge" process from 20 to 80 cub. yds. or more may be deposited in the settling tanks. The following analyses (parts per million) show the results before and after treatment by the two processes:—

Month, 1915.		Suspended matter.	Nitrogen as:			
			Free NH_3 .	Albuminoid NH_3 .	Organic N.	Nitrate.
August	Sewage	253	14.6	7.88	29	0.15
	Effluent, Imhoff	105	16.2	6.10	27	0.19
	Effluent, activated sludge	14	3.8	3.19	6	6.00
September	Sewage	300	13.5	8.81	29	0.25
	Effluent, Imhoff	116	15.4	7.10	27	0.19
	Effluent, activated sludge	8	5.7	2.22	9	5.01

The dry "activated sludge" contained from 1 to 4.5% of nitrogen, but it would be necessary to remove part of the 98 to 99% of water before the material could be sold as a fertiliser. The best means of effecting this was found to be a preliminary settling and decantation, whereby the moisture content was reduced to about 96%, followed by mechanical pressure, reducing the water to 75%, and drying the press cake in a drying apparatus to obtain a product with 10% or less of water. The colloidal matter in the sludge does not interfere with the pressing, and little if any nitrogen is lost in the drying process whether indirect heat (*e.g.*, by a steam jacket) or semi-direct heat is used. The cost of the finished product is estimated at \$8.00 to \$12.00 per ton, including labour, fuel, and depreciation of plant. Four samples of the dried sludge (10% moisture) contained 4.36 to 5.06% of nitrogen as ammonia, and 0.39 to 0.81% of available phosphoric acid. The conclusion is drawn that the dried sludge is a good fertiliser without any further additions, and that its market value at the present time is about \$9.00 to \$15.00 per ton. It could therefore be profitably produced for a large local market.—C. A. M.

Inflammability of carbonaceous dusts in atmospheres of low oxygen content. Brown and Clement, *See* HA.

PATENTS.

Water softening: Apparatus for — G. J. Gibbs, Preston, Eng. Pat. 101,591, June 1, 1916. (Appl. No. 7768 of 1916.)

The pipe conveying the raw water to the apparatus is provided with a valve which divides the water into two portions, passing upwards in two pipes of the same height and being delivered, one into the top of the measuring and reagent apparatus, and one into the top of the reaction tank. The water passing through the reagent apparatus is overdosed with the reagent and passes on into the reaction tank, where it mixes with the rest of the water. By means of the valve, the proportions into which the water is divided can be finely adjusted while the apparatus is at work, the proportions being indicated on a scale. The two branch pipes for the raw water are as nearly alike as possible in length and disposition, so that they each discharge against the same static head, whereby the water in the two pipes is kept at a constant ratio for a given setting of the valve. Instead of one valve, the pipe for the raw water may bifurcate before being valved, and in this case each branch pipe carries an independent valve.—J. H. J.

Filling [jewellers' waste wash] water: Process and means for — F. P. Boland, Providence, R.I. U.S. Pat. 1,217,397, Feb. 27, 1917. Date of appl. Nov. 23, 1915.

JEWELLERS' waste wash water, containing non-liquid particles of precious metals in suspension, is collected in a tank from which it flows slowly

through a restricted opening into the top of another tank of the waste water, whereby particles not readily burned are collected in the bottom of the first tank, and particles of precious metals in suspension are carried over into the second tank. The water in the second tank is slowly withdrawn through a restricted opening, whereby the particles of precious metal are separated as before. The discharge from the second tank is filtered through a combustible filter, which is then burned, and the precious metals collected.—J. H. J.

Water-purifying apparatus [; *Electrolytic* — J. D. Kynaston, Washington, D.C. U.S. Pat. 1,219,333, Mar. 13, 1917. Date of appl. Nov. 15, 1916.

WATER enters at the bottom of an upright conveying vessel, and has a gyratory motion imparted to it. As it passes up through the vessel, it meets electrodes arranged as battle-plates connected in series, the anodes being of aluminium and the cathodes of carbon. The water leaves at the top of the vessel and passes to the bottom of a filtering and settling tank.—J. H. J.

Liquid purifying apparatus. L. Linden, Claygate, Surrey, Eng. Pat. 101,710, Mar. 10, 1916. (Appl. No. 3613 of 1916.)

IN a vertical apparatus for the sterilisation of liquids by violent agitation (*see* Fr. Pat. 478,797; this J., 1916, 1129), the liquid to be purified is admitted at the top and falls on to filtering material contained in a holder supported on trunnions at each side, so that it can be inverted. After passing through the filter, the liquid is received on the floor of the upper part of the apparatus and then passes through a valve into the intermediate part of the apparatus, which has the form of a double-walled cylinder in the centre of which is mounted a vertical Archimedeian screw driven by outside power. When the liquid has filled the cylinder, the screw is set in motion and forces the liquid violently against the sides, and at the same time exerts a downward force so as to cause a circulation of the liquid downwards in the cylinder and upwards between the double walls. When the liquid has circulated sufficiently, a valve in the floor of the cylinder is opened and the liquid passes on to filtering material contained in a tray. From the filter, the liquid is received in the bottom of the apparatus which is of cup-shaped form, tapped at the bottom, and acts as a reservoir. Tubes pass into the sides of the reservoir, through which air can be blown into the liquid. When the filtering material requires to be cleaned, the top filter is inverted and the liquid allowed to flow through as before, the washings being run off by a pipe in the side. The bottom filter can be removed bodily through a door in the side and replaced by another tray of clean material. A portable form of the apparatus can be mounted on a motor vehicle, and the motor of the vehicle can be used to supply the power for the working of the apparatus.—J. H. J.

Sewage and other foul liquids; Apparatus for aerating—R. Ames, Brighton, Eng. Pat. 164,361, Feb. 25, 1916. (Appl. No. 2850 of 1916.)

THE apparatus consists of a circular tank in which is a central standpipe supporting a chamber carrying horizontal radial arms, capable of being revolved above the level of the liquid in the tank. The sewage enters by a pipe, in which it is mixed with compressed air, along the bottom of the tank to the central standpipe, from openings in the bottom of which the sewage passes into the body of the tank. Air is supplied to the chamber carrying the radial arms, and pipes depend from these arms nearly to the floor of the tank, with atomisers attached to their ends. The atomisers consist either of a metal casing containing a porous block or layers of wire gauze, or of a hollow metal block with narrow slots. The radial arms are rotated by the pressure of the escaping air on the liquid, or by mechanical means. The purified liquid is drawn off intermittently or continuously. —J. H. J.

Sewage containing organic matter; [Electrolytic] purification of—G. ter Meer, and K. Reubold, Hannover-Linden. Ger. Pat. 294,957, Sep. 8, 1911.

THE precipitation of colloidal organic matter from sewage can be effected electrolytically in the presence of a small quantity of chemical precipitant. Using iron or aluminium electrodes, oppositely charged hydroxides in the colloidal form are produced which bring about the coagulation of the organic colloids. This fails sometimes because the latter behave as protective colloids. In such cases the addition of electrolytes, in general, is inadequate, but the addition of aluminium sulphate is effective if from one-quarter to one-third of the quantity which would itself cause precipitation of the colloid, is taken. —H. J. H.

Preserving-gas, J. N. Alsop, Assignor to Alsop Electrical Co., Owensboro, Ky. U.S. Pat. 1,219,527, Mar. 20, 1917. Date of appl., Apr. 28, 1913.

"VAPORISED products of wood" are mixed with atmospheric air, and the mixture is exposed to the action of an electric arc. The resulting gas has germicidal and therapeutic properties.—J. H. J.

Sewage and other waste liquids; Apparatus for treating—T. K. Irwin, Assignor to Anglo-Continental Fertilizers Synd., Ltd., London. U.S. Pat. 1,220,990, Mar. 27, 1917. Date of appl., Sept. 4, 1914.

SEE Eng. Pat. 20,816 of 1913; this J., 1914, 565.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Acetylsalicylic acid; Analysis of—M. François. J. Pharm. Chim., 1917, 15, 213—222.

To detect the acetic acid residue in the acetylsalicylic acid molecule, the substance is treated with an excess of calcium hydroxide and a small quantity of water; calcium acetate and calcium salicylate are thus formed, the latter being insoluble. After 1 hour, the mixture is filtered, the calcium salicylate washed with a small quantity of water, the filtrate evaporated to dryness, the residue gently ignited to destroy any remaining trace of salicylate, and the usual tests for acetates then applied. Acetylsalicylic acid should volatilise completely when heated (the presence of sugar, tartaric acid, and certain alkaloids such as quinine

may often be detected by the odour of the vapour given off during ignition), and should not give a violet coloration with ferric chloride (absence of free salicylic acid). Its m. pt. is 132° C.; in determining the m. pt. the oil-bath should be heated to 125° C. before the capillary containing the substance is introduced, and the temperature then raised at the rate of 1° per min. Acetylsalicylic acid may be determined by means of the acid or saponif. values of the substance. Two samples of "aspirin" examined by the author consisted of crystallised magnesium sulphate, 53.2 and 48.4, lactose, 38.9 and 46.6, acetylsalicylic acid (containing free salicylic acid), 7.8 and 7.9%, respectively.—W. P. S.

Hexamethylenetetramine; Explosive peroxide derivative of—A. Leulier. J. Pharm. Chim., 1917, 15, 222—229.

By dissolving 140 grms. of hexamethylenetetramine in hydrogen peroxide, adding 140 grms. of pure nitric acid, then introducing more hydrogen peroxide until the total weight of the mixture was 1500 grms., and keeping this mixture at 20° to 25° C. for 3 hours, a crystalline precipitate was obtained which, when dried, weighed 60 grms. This substance contained carbon, 31.46, hydrogen, 10.06, oxygen, 45.50, and nitrogen, 10%; it was practically insoluble in water, ether, and cold alcohol, but soluble in hot alcohol. It exploded violently when struck with a hammer or when heated, the force of the explosion being about two-thirds of that of melinite. Dilute sulphuric acid converted it into formaldehyde and ammonium sulphate. Its composition and properties showed it to be $\text{NH}(\text{CH}_2\text{CH}_2\text{O.OH})_2$, and to be identical with the "hexamethylene triperoxide," prepared previously by Von Girsowald (this J., 1912, 1058), although the latter considered that the substance contained 2 atoms of nitrogen in its molecule.—W. P. S.

Organic compounds containing sulphur; Action of pyridine and piperidine on—M. Raffo and O. Balduzzi. Gazz. Chim. Ital., 1917, 47, I., 65—73.

WHEN a solution of thiourea in pyridine is boiled, decomposition of the thiourea takes place, with the formation of hydrogen sulphide, guanidine thiocyanate, and ammonium trithiocarbonate as the final products. Cyanamide is probably formed as an intermediate product, as in the case of the decomposition effected by yellow mercury oxide, but this would at once react with the ammonium thiocyanate also produced in the reaction to form guanidine thiocyanate. In like manner thioaminophenol when heated with pyridine yields hydrogen sulphide and diaminophenyl sulphide, and thioacetanilide gives hydrogen sulphide and acetanilide. Piperidine has an analogous desulphurising action upon organic sulphur compounds. For example, diphenylthiourea when dissolved in piperidine and boiled, yields as the final products of decomposition, aniline, triphenylguanidine, and piperidine thiocarbonate (m. pt. 169—171° C.).—C. A. M.

Distillation; Studies in steam—Part IV. Propionic, butyric, valeric, and caproic acids. Part V. Some applications of Duclaux's method. H. D. Richmond. Analyst, 1917, 42, 125—139. (See also this J., 1908, 705, 897.)

IN continuation of the work on formic and acetic acids, propionic, butyric, iso and active valeric, normal caproic, and diethylacetic acids were purified, and their dilute solutions distilled in fractions, as previously described. The rate of

distillation relative to that of water, a , was calculated from the ratio,

$$\frac{\log y}{\log x}$$

where $x = 1 - \frac{\text{percentage of total water distilled}}{100}$

and $y = 1 - \frac{\text{percentage of total acid distilled}}{100}$

Continued purification of the acid in each case led to a constant value of a being approached for the A and B fractions. The factors for the different acids at $N/100$ concentration were in close agreement with those calculated from the formula $a = 0.4013 \times 1.72^n$, where n is the value in the formula $C_nH_{2n+1}COOH$, as shown in the table:—

Acid.	a (from experiment).	n .	0.4013	1.72^n .
Formic	0.4013	0	0.4013	
Acetic	0.677	1	0.69	
Propionic	1.224	2	1.18	
Butyric	2.00	3	2.04	
Valeric	3.50	4	3.51	

The results with the caproic acids do not agree with the formula. The estimation of the factor a provides a means of determining the purity of these acids; and in the case of a mixture of two homologous acids enables the relative proportions to be calculated; thus with a mixture of acetic and propionic acids, which was made to contain 0.488 mol. of propionic to 0.512 of acetic, the mean result indicated 0.493 mol. of propionic acid as shown in the following table giving the values for the successive fractions:—

x .	y .	y calc. for acetic.	y calc. for propionic.	y corrected	Ratio $\frac{P}{A+P}$.
0.900	0.9025	0.931	0.8755	0.904	0.513
0.9785	0.807	0.8585	0.7565	0.809	0.595
0.698	0.7115	0.782	0.641	0.714	0.500
0.5985	0.619	0.7045	0.5295	0.620	0.488
0.4985	0.523	0.6215	0.4215	0.5245	0.492
0.3985	0.429	0.533	0.320	0.430	0.488
0.2995	0.2375	0.333	0.1365	0.238	0.486
0.0995	0.132	0.206	0.0575	0.134	0.498

The use of Duclaux's method is best exemplified by the analysis of acids of the acetic series. During the distillation of a simple mixture of two such acids, the amount distilled in each fraction is calculated for each of the acids as a percentage of the acid present at the commencement: an agreement between the ratios deduced for each fraction will show that no other acids are present, and the mean ratio will give the molecular proportions. The quantity of butyric acid present in acetic acid can advantageously be estimated in this way as an alternative to the method of titration of the weighed anhydrous acid with standard alkali. In discussing the analysis of acetic anhydride, the method of Menschutkin and Wasiljew (J. Russ. Phys. Chem. Soc., 1889, 21, 190), is referred to as the best, and as it escaped abstraction in English is given in detail by the present authors. The purity of acetyl compounds can be determined by separating the acetic acid by hydrolysis and distilling in fractions. With small quantities of salicylic acid present in acetic acid, if the acid is exactly neutralised, then 99% of the solution distilled, while nearly 80% of the acetic acid is thus removed only 15% of the salicylic acid is lost, and the delicacy of the test is thus greatly enhanced. Substituted malonic acids (e.g., a mixture of malonic, ethylmalonic, and diethyl-

malonic acids) can be conveniently tested by heating to 190° C., when conversion into the corresponding members of the acetic series occurs and the product may be examined by the Duclaux method. After deducting for the estimated amount of free acetic acid, the values of y are compared with those calculated for butyric and diethylacetic acids, and the proportions of these deduced.—J. N. P.

PATENTS.

Medicinal aluminium preparation; Method of manufacturing a—, Monneron et Guye, Lausanne, Switzerland. Eng. Pat. 104,609, June 23, 1916. (Appl. No. 8878 of 1916.) Under Int. Conv., June 5, 1916.

AN aluminium preparation which dissolves gradually in the intestines and there acts as a mild astringent, is produced by precipitating an aluminium salt with caustic alkali in the presence of a protective colloid, rendering the colloid insoluble, and washing out the alkali salt with water. *Example*:—To a clear solution of 200 grms. of aluminium sulphate in 500 c.c. of hot water is added 30 grms. of gelatin dissolved in 300 c.c. of warm water. The acid reaction is exactly neutralised with 35% soda lye (about 145 c.c.), and 18 grms. of tannic acid dissolved in 100 c.c. of warm water is added with constant stirring. The thick flaky pulp produced is filtered, washed free from sodium sulphate, dried, and pulverised. It is useful in the treatment of diarrhoea.—F. Sp.

Cephaeline butyl ether and salts thereof. J. W. Meader, Indianapolis, U.S.A. Eng. Pat. 104,652, July 18, 1916. (Appl. No. 16,036 of 1916.) Addition to Eng. Pat. 11,717, Aug. 13, 1915 (this J., 1916, 1271).

CEPHELINE butyl ethers (as distinguished from the isobutyl ether claimed in the principal patent) are made by the action of an alkali metal and a butyl halide on cephaeline. The details of the preparation and the properties of the product are the same as for the isobutyl ether.—F. Sp.

Cephaeline allyl ether and process for making same. J. W. Meader, Assignor to The Eli Lilly & Co., Indianapolis, Ind. U.S. Pat. 1,209,575, Mar. 20, 1917. Date of appl., Jan. 25, 1916.

CEPHELINE allyl ether, $C_{25}H_{37}O_3N_2OC_3H_5$, is prepared by treating cephaeline with sodium ethylate and allyl bromide.—J. H. J.

Nitromethane and homologues; Preparation of—, H. Krause, Dresden. Ger. Pat. 294,755, Dec. 1, 1915.

A FINELY powdered mixture of a nitrite and a salt of an alkylsulphuric acid is made into a cream with water and distilled. Above 100° C. the nitroparaffin passes over and this continues after the mass has been evaporated to dryness. Decomposition of the alkyl sulphate to form sulphuric acid or an acid sulphate is to be avoided as it causes a loss of yield. The sulphuric acid formed liberates nitrous acid, and this reacts with the nitroparaffin causing a further loss of yield. To obviate this, a little alkali or salt with an alkaline reaction is added to the mixture before distillation. The yield of nitromethane is 50% of theory and of nitroethane 35%.—H. J. H.

Hydrocarbons and their derivatives; Preparation of—, Badische Anilin u. Soda Fabr., Ger. Pat. (A) 295,202, May 31, 1914, and (B) 295,203, June 23, 1914. Additions to Ger. Pat. 293,787 (see Fr. Pat. 468,427 of 1914; this J., 1914, 984).

(A) IS the reactions between hydrogen and carbon monoxide under pressure in contact with catalysts,

spontaneous local heating and deposition of free carbon can be hindered by increasing the thermal conductivity of the contact mass. Where possible the catalyst may be used in the form of metallic gauze, wool, or turnings, or it may be deposited on metal or on a ceramic mass mixed with metallic particles. (B) The catalyst may be a metallic carbide preferably of the iron group of elements. The carbide as such may be used, *e.g.*, cast iron, or it may be prepared *in situ* as a result of the carburising of a low-carbon steel by the carbon monoxide or hydrocarbons in the compressed gas mixture.—H. J. H.

Ethyl ether; Process for purifying — G. Michaelis. Albany, N.Y., U.S.A. Eng. Pat. 105,204, Oct. 24, 1916. (Appl. No. 15,145 of 1916.)

SEE U.S. Pat. 1,189,602 of 1916; this J., 1916, 907.

Altol; Manufacture of — W. Herrmann and M. Mugdan, Assignors to Consortium für Elektrochemische Industrie, Nuremberg, Germany. U.S. Pat. 1,220,746, Mar. 27, 1917. Date of appl., Sep. 3, 1913.

SEE Eng. Pat. 19,463 of 1913; this J., 1914, 219.

Hydrocarbons; Producing partially-hydrogenised monocyclic — O. Schmidt, Ludwigshafen, and K. Hochschwender and T. Eichler, Mannheim, Assignors to Badische Anilin u. Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,221,382, Apr. 3, 1917. Date of appl., Oct. 11, 1912.

SEE Fr. Pat. 441,203 of 1912; this J., 1912, 843.

XXIII.—ANALYSIS.

Photometer; A polarisation flicker — and some data of theoretical bearing obtained with it. H. E. Ives. Phil. Mag., 1917, 33, 360—380.

In the instrument described a double image prism forms two images of each half of the photometric field, the horizontally polarised image of one half being superposed on the vertically polarised image of the other half; a rotating Nicol prism alternately extinguishes each half but gradually and with no mechanical edge effect. The rotating Nicol may be placed near the eye, in which case its faces must be at right angles to the beam of light, or it may be placed between the double image prism and the diaphragm, when the faces may be oblique

to the beam of light. A special mixture photometer was used having two similar flashed opal glass plates mounted one over the other on a common vertical axis parallel to their faces and rotatable in opposite directions by means of suitable gears: this arrangement was placed at the intersection of two photometer tracks and viewed from behind. The effect of rotation of the Nicol on a polarised beam follows the cosine law postulated in previous discussions (Phil. Mag., 1911, 708; 1916, 290). The relationships between relative and absolute intensities of compared fields and critical speeds are shown to be in agreement with theory. The flicker photometer is specially adapted for colour difference comparisons owing to the failure of hue discrimination as compared with brightness discrimination with rapid fluctuations and the amount of this failure has been determined.—B. V. S.

High temperature measurements without platinum instruments. M. Neumann. Chem.-Zeit., 1917, 41, 288.

A NEW thermo-element recently introduced for the measurement of temperatures between 900° C. and 1100° C., is constructed of nickel and nickel-chromium and is very reliable. An improved and simplified form of optical pyrometer has also been introduced, in which the regulating electrical resistance is in the form of a ring on the telescope tube, which is made of aluminium.—F. C. T.

Silica; Accurate determination of — in commercial analysis. F. G. Hawley. Eng. and Min. J., 1917, 103, 511—513.

ATTENTION is directed to sources of error in the determination of silica due to the solubility of silica in hydrochloric acid, the presence of silica in the fusion mixture itself, and to impurities retained by the washed silica. The solubility of the silica, which may amount to 2% in samples containing less than 20% of silica, may be diminished by heating the saline residue at 150° C. for 30 mins., then adding 15 c.c. of 60% hydrochloric acid, heating the mixture to boiling for 3 mins., and collecting the silica on a filter where it is washed successively with water, dilute hydrochloric acid, and water. To determine silica in ores containing much lead, copper, antimony, etc., the ore may be fused in a nickel crucible with a mixture of sodium hydroxide and sodium peroxide (equal parts by weight), followed by the above method of separation. Under these conditions, the loss of silica by solution is about 0.4%, but this loss is balanced approximately by impurities in the silica and the quantity of the latter derived from the fusion mixture.—W. Gases: Apparatus for indicating the composition of —. H. Haupt and M. Werner, Berlin. U.S. Pat. 1,220,037, Mar. 20, 1917. Date of appl. Apr. 9, 1915.

THE composition of gases is indicated by using the principle of diffusion. A diffusion chamber and an air supply chamber are combined with a number of similar auxiliary chambers, separated from each other, and having their opposite end walls provided with ports controlled by valves mounted on a rotating shaft. The valves are so arranged as to permit, during each half turn of the shaft, an exchange of air between the auxiliary chambers, the diffusing chamber, and the supply of air.—W. F. F.

Books Received.

GAS CHEMISTS' HANDBOOK. Published by the American Gas Institute, 29, West 39th Street, New York City. 351 pages, 8 $\frac{1}{2}$ × 6 in. Price \$3.50 in the United States and Canada; elsewhere \$3.75.

THE Committee on Chemical Tests of the American Gas Institute, under the chairmanship of C. C. Tutweiler, has for the past two years been engaged in revising the first edition of this book, compiled in 1911 by W. H. Fulweiler. Some of the methods there described have been discarded in favour of simpler and more accurate processes, and the Committee is continuing its work with a view to collecting a number of methods of analysis all of which are approved by the Institute. The methods given for the analysis of coal and coke, cements and iron and steel are the official methods of the U.S. Bureau of Mines and of the American Society for Testing Materials.

The analytical methods are subdivided as follows: I. Coal, coke, gas oil, purification material. II. Illuminating gas, ammonia, tar, cyanogen. III. Impurities in gas. IV. Tar products. V. Constructional materials, alloys, lubricating oils.

THE CHEMISTS' YEAR BOOK, 1917. Edited by F. W. Atack, Sherratt & Hughes, 34, Cross Street, Manchester. In two vols. 1030 pages, 6 × 4 in. Price 10s. 6d.

THE third edition of this useful Year Book fully maintains the standard of its predecessors, and has, it is to be hoped, now established for itself a permanent place in our periodical literature. New sections are included on "Analysis of essential oils," by L. G. Radcliffe; "Efficiency of boiler plant," by T. O. Morgan; "Cement," by A. Grounds; and "Paints and pigments"; while the section on "Textile fibres" has been re-written by W. F. A. Ermen, and other sections have been considerably revised.

THE FLOTATION PROCESS. Compiled and edited by T. A. Rickard. Mining and Scientific Press, Chicago. 364 pages, 9 × 6 in. Price 8s. 6d.

THIS is a useful collection of papers published in the *Mining and Scientific Press* on the practice and theory of the flotation process, which has developed so largely during the past five years (it is stated that fully 50,000 tons of ore is being treated daily in the United States by this method). The contributors include G. L. Allen, T. M. Bains, J. A. Block, C. Butters, D. Butler, J. M. Callow, J. E. Clemell, W. H. Coghill, W. F. Copeland, A. E. Brucker, C. T. Durell, F. A. Fahrenwald, J. Hebbard, W. H. Kenyon, V. F. S. Low, E. P. Mathewson, W. Motherwell, D. H. Norris, T. A. Rickard, O. C. Ralston, W. A. Scott, W. Shell-shear, and J. H. Wise.

CONCENTRATING ORES BY FLOTATION. By T. J. Hoover. Mining Magazine, Salisbury House, London, E.C. 320 pages, 9 × 6 in. Price 12s. 6d.

THE progress that has been made in the applications of the flotation process since the publication of the second edition of this book, in 1914, has necessitated a further edition. In this however, the text of the second edition has been retained in its entirety, and a chapter on recent progress has been added to bring the matter up to date. The early chapters of the book deal with the history of the process and the litigation which has resulted in connection with it. The Potter-Delprat, De Bavay, Elmore, and Minerals Separation processes are fully described, and some of the other processes are also considered. In the chapter on more recent work, the fallow process is described fully, and an account is given of the characters of the oils and soluble frothing agents used in the process. The bibliographies and lists of patents are very complete.

THE MANUFACTURE OF SULPHURIC ACID AND ALKALI. By G. LUNGE. Supplement to Vol. I. Gurney & Jackson, 33, Paternoster Row, London, E.C. 317 pages, 8 $\frac{1}{2}$ × 5 $\frac{1}{2}$ in. Price 15s.

THE author has collected, in this supplementary volume, notes on the various papers and patent specifications on sulphuric and nitric acids which have appeared since the publication of the fourth edition in 1913, and has also added particulars obtained from official reports and private communications. To facilitate reference, the chapters are numbered in the same way as those in the original volume.

Official Notices.

ANNUAL GENERAL MEETING, 1917.

In accordance with the provisions of By-law 64, notice is hereby given that the Annual General Meeting will be held in The University Buildings, Edmund Street, Birmingham, at 10.30 a.m. on Wednesday, July 18th, 1917. A programme of the proceedings will be issued later.

In accordance with the provisions of By-law 24, those members whose names are printed in *italics* in the List of Council will retire from their respective offices at the forthcoming Annual Meeting.

Prof. Henry Louis has been nominated to the office of President under By-law 20; Dr. Charles Carpenter has been nominated Vice-President under By-law 20; Mr. John Gray, Mr. A. R. Ling, Prof. R. F. Ruttan, and Mr. J. T. Wood have been nominated Vice-Presidents under By-law 21.

Mr. A. G. Bloxam, Mr. W. J. Rees, Mr. Edwin Thompson, and Prof. James Walker have been nominated to fill the four vacancies among Ordinary Members of Council, under By-law 25. No ballot will be required.

J. P. LONGSTAFF,
Secretary.

REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY.

The first volume of these reports is now ready. As the issue is strictly limited, those who desire to obtain copies are advised to apply for them without delay. The price is 3s. to members and 5/6 to non-members, including postage.

PROHIBITED EXPORTS.

A Proclamation, dated May 10th, consolidates, amends, and adds to the list of goods which were prohibited to be exported from the United Kingdom to certain or all destinations, by the Proclamation of May 10th, 1916, as amended and added to by subsequent Orders of Council (see this J., 1916, 620, 710, 756, 870, 909, 982, 1086, 1134, 1184; 1917, 49, 102, 240, 307, 356, 404, 477). The full text of the Proclamation will be found in the "Board of Trade Journal" for May 17th, pages 360-375.

PROHIBITED IMPORTS.

A Proclamation, dated May 10th, prohibits as from that date the importation into the United Kingdom of gum copal, gum kauri, and manufactures of rubber, except under licence given by or on behalf of the Board of Trade.

SEEDS, OILS AND FATS.

With reference to the Orders of the Minister of Munitions made and published on the 1st May and the 9th May, 1917, restricting dealings in seeds, oils and fats, the Minister of Munitions gives notice that he licenses until further notice all sales and purchases of special quality seeds of any of the descriptions referred to in the said Orders specifically for cultivation irrespective of quantity, and also all sales and purchases of home melt tallow and grease for any purposes and in any quantities.

SEEDS, OILS, AND FATS.—MINISTRY OF MUNITIONS ORDER, MAY 9th, 1917.

The Minister of Munitions hereby orders that on and from the day following the date of this Order until further notice the schedule hereto shall be deemed substituted for the second schedule to the Order of the 1st May, 1917 (this J., 1917), and accordingly no person shall purchase sell or deal in or offer to purchase sell or deal in any of the articles specified in the schedule to this Order at a price exceeding the price given. This restriction on price shall not apply to any sale or purchase of any of the said articles which under clause 1 of the Order of the 1st May, 1917, is authorised to be effected without any license issued by or under the authority of the Minister of Munitions nor to any sale or purchase of special quality seeds sold and purchased specifically for cultivation.

Schedule.—Maximum prices (per ton).—Seeds, nuts, and kernels. Castorseed, £37; copra, £46; cottonseed, £19; gingelly (sesamé) seed, £32; ground nuts, £32; hempseed, £30; linseed, £30; nigerseed, £28; palm kernels, £26 10s. East Coast Ports; £26 West Coast Ports; rapeseed, £30. All these prices are net prices for seeds, nuts, and kernels in bags ex ship, quay or warehouse in the United Kingdom. *Oils and fats.*—Castor oil, £80 per ton; coconut oil (crude), £70; (refined), £85; cotton oil (crude), £60; (refined soap oil), £67; (refined edible oil), £75; (American refined), £95; gingelly (sesamé) oil, £65; ground nut oil (crude), £78; (refined), £90; kapokseed oil (crude), £55; (refined), £70; linseed oil (raw), £58; (boiled), £61; (refined), £63; nigerseed oil (crude), £60; oleo oil, £120; palm kernel oil (crude extracted), £51; (crude crushed), £52; (refined), £67; palm oil, £44; premier jus, £91; rapeseed oil (crude), £66; (refined), £71; (edible), £81; soya oil (crude), £60; (refined) £75; seal oil (crude), £60; tallow (imported), £68. All the above prices are for oil or fat net naked ex ship, mill, or warehouse in the United Kingdom. Packages may be charged extra at current market rates but not exceeding £4 per ton on the oil or fat.

SUPPLIES OF SICILIAN SULPHUR.

The Minister of Munitions announces that, in connection with the distribution of Sicilian sulphur, the Italian Government have allotted certain specified quantities to each of the Allied Governments, and requested that His Majesty's Government should purchase direct from the Italian Government the quantity allotted to Great Britain, and should be responsible for its distribution.

His Majesty's Government have agreed to this course, and the following Committee has been appointed to deal with the matter:—Mr. A. D. Cooper, Foreign Office; Mr. B. A. Collins, India Office; Mr. C. W. Dixon, Colonial Office; Mr. R. J. Thompson, Board of Agriculture and Fisheries; Mr. F. Gossling, Board of Trade; Mr. R. A. Alston, Ministry of Munitions; and Mr. H. S. Mingard, Ministry of Munitions, who will act as Secretary to the Committee.

In view of the increased demand for sulphur in connection with the production of explosives, it was found necessary, after careful consideration, that the export of sulphur should be prohibited, but, provided every care is exercised to avoid waste in the use both of sulphur and of products and compounds in the manufacture of which

sulphur is consumed, it is anticipated that agriculturists and manufacturers will not experience any great difficulties.

The Committee has decided to offer to supply imported sulphur in lots of not less than 5 tons for use in approved trades and industries. The prices for the present, including delivery to the purchaser's nearest railway station, will be:—Flowers of sulphur, £23 per ton; roll brimstone, £21; thirds, £12 10s. From the prices mentioned above a discount of 2½%, will be allowed to recognised sulphur merchants and dealers, but not to consumers. Applicants claiming this discount must furnish satisfactory evidence that they were recognised sulphur merchants or dealers before the war. The Committee understands that "recovered" sulphur can be procured, in the ordinary way of business, from the home producers.

Application for sulphur must be made on special forms, which may be procured from the Secretary, Sulphur Committee, Ministry of Munitions, Explosives Department, Storey's Gate, S.W.1. All applications must be accompanied by remittance of the purchase price in full.

Editorial.

RESEARCH IN THE CERAMIC INDUSTRY.

The immense importance of the refractory materials industry has recently been brought into increasing prominence, in view of the development of new industries, with their needs of constructional materials capable of withstanding a wide range of stresses. Quite recently a "Refractory Materials Section" of the English Ceramic Society has been formed to deal specially with this branch of the subject, whilst on the educational side may be noted the increased activities and usefulness of the Stoke-on-Trent Pottery School, and the opening, in December last, of the Ceramic Engineering Building of the University of Illinois; an interesting description of this building is given in University of Illinois Bulletin No. 12, Vol. 14, copies of which may be obtained from the Registrar of the University, Urbana, Ill., U.S.A.

All these movements indicate the growing appreciation of the necessity for research on the refractory materials—a subject which, owing to the complexity of the problems involved, has received all too little attention during recent years. In order to promote some definite scheme according to which such research work might be organised and carried out, a conference was held in March at which representatives of the Geological Survey, the National Physical Laboratory, and the principal technical Societies concerned were present, and as the result of their deliberations a Committee was appointed to enquire into the extent of the research work now in progress, the facilities for such work, and the facilities existing for collecting and making available published information on the subject. The Committee is also engaged in collecting information as to the various problems which call urgently for action. This Society is represented on the Committee by Prof. J. W. Coble, of the University, Leeds, who will be glad to receive suggestions for research on refractory materials in connection with chemical industries which call for immediate attention. Some of the problems in connection with metallurgy, mentioned by Mr. Cosmo Johns at the May meeting of the Iron and Steel Institute (see page 536), are also applicable to chemical industries, but there are numerous others which require investigation, especially in regard to the

behaviour of refractory materials when subjected to chemical action at high temperatures or under high pressures; particularly is this the case in regard to the materials which have come into use during more recent years, such as alundum, siloxicon, calcined magnesite, chromite, zirconia, etc. It is to be hoped that the Committee, mentioned above, will be advised of these problems as soon as possible, in order that their work may be facilitated.

New York Section.

Meeting held at Chemists' Club on March 23rd, 1917.

FOOD VALUES.

BY GRAHAM LUSK.

(Abstract.)

The author referred to the report of the Eltzbacher Commission on the food situation in Germany at the outbreak of war, and to the various errors made in that report, such as overestimates of the available supply and underestimates of the amounts required by women who took up the work of men and by growing children. In Germany it is the urban dweller who has suffered in regard to food supply, the farmer living in his usual manner. The circumstance that in spite of the undoubted shortage of food the German people are not starving, is explained by the fact that in extreme cases of under-nutrition it is possible to reduce the food supply to only 40% of its former level.

Extended reference is made to the report of the Royal Society's Commission on food supplies in Great Britain, which has already been fully noted (this Journal, 1917, 279), and the author points out that the restricted diet (flour, meat, and sugar) which the Food Controller has requested the population to adhere to, would yield about 1750 calories per "man" daily, leaving the individual to supply about an equal quantity from other sources.

In regard to the question of calorific value, the author urges that as far as possible all foods should be purchased with a knowledge of their calorific and nutritive values, and that packages should be labelled with this information. Regard should also be had for the different values of the various proteins. It is pointed out that at the present time the prices of cereal products are all in proportion to their calorific values.

Experiments were quoted to show that meat in quantity is not necessary to maintain vigorous muscular power, small amounts only being needed to replace the protein loss of the organism. It is the carbohydrate foods and fats which provide the greater part of the requisite energy.

The author concluded by giving particulars of a dietary for five people, in which very small quantities of meat had a place, costing \$1.11 daily for 4400 calories. The principal items in this diet are as follows, per day: milk, 3 qts.; bread, 2 lb.; cereal, ½ lb.; oleomargarine, ½ lb.; rice or macaroni, 1 lb.; dry "navy" beans, 10 oz.; fat pork, 6½ oz.; dry fruit, 1 lb.

Prof. Lafayette B. Mendel also read a paper on "Food Fads."

PROF. J. W. COBB IN THE CHAIR.

SOME FUTURE LINES OF ADVANCE IN COKING PRACTICE.

BY G. E. FOXWELL, ASSOC. M.I.M.E.

In this paper the author's intention is to bring forward some of the problems at present awaiting solution in connection with the coking of coal and to indicate briefly some lines on which research might with advantage be undertaken.

The coking industry, like all other branches of chemical industry, is faced with many problems—some of urgent importance, others not immediately vital—but most of which will require to be solved in the near future.

It will be necessary to speed up considerably, to shorten the carbonising period in order to increase the output. In this country probably no coke ovens, even those working with low-volatile coal, are carbonising consistently in less than 24 hours. In America quite different conditions prevail. The carbonising period is very much shorter, and larger ovens are in use. To cite an actual instance:—At an installation of 560 Koppers ovens at Gary, U.S.A., each oven has a capacity of 12½ tons of coal per charge and the charge is burnt off in 16½ hours. The coal contains 18% of volatile matter and yields 12,200 cu. ft. of gas per ton. Just under 4 galls. of tar and 18 lb. of sulphate of ammonia are also produced per ton of coal carbonised. Such coal in an English oven would probably produce 10,000 cu. ft. of gas, 5–6 galls. of tar, and 20 lb. of sulphate of ammonia, and would take 26 hours to burn off. Moreover, very few English ovens take a charge of more than 10 tons of coal, and in most cases only 8 tons.

The secret of the quick-burning American oven is said to be that the walls are made of brick containing 95% of silica, and this, owing to its higher fusing point, enables the ovens to be worked at a much higher temperature. In England, on the other hand, brick containing 80% of silica is generally used.

A great deal of work is required in connection with refractory materials, both in connection with their manufacture and use. The ideal brick for coke oven walls should be hard, in order not to break in transit or wear away when pushing out the coke; it should be a thoroughly good conductor of heat; the expansion and contraction should be under 1%, and the tendency for the brick to crack on cooling should be as small as possible. The brick should also be resistant against chemical action, as coke oven walls in certain districts are subjected to a very serious corrosion, owing, it is supposed, to the action of the soluble salts, and particularly sodium chloride, contained in the coal.

Coke oven bricks are at present far from being satisfactory. As supplied by different makers they are of very uneven quality, some being very friable, others offering considerable resistance to the passage of heat, others again cracking badly on cooling from a high temperature, while none resist corrosion. Here lies an exceedingly wide field for research.

Another point of difference between English and American practice lies in the scientific mixing of coals before coking. English coking plants are usually—though by no means always—built at a colliery. The slack coal from all the different pits is sent to the ovens, and as long as a good quality of coke is produced no further attention is

paid. Certain coals do not yield a saleable coke when carbonised alone, and these are not sent to the coking plants. It so happens that, generally speaking, coals yielding a poor quality of coke give a higher yield of by-products than coals yielding good coke. If scientific blending were to be carried out, much of our non-coking coal could be used in the coke oven and the yield of by-products increased without materially affecting the quality of the coke. In American practice the plant is worked for some days on a known mixture of certain coals and the results noted. The proportions are then changed and a test again carried out. By proceeding in this way the best mixture for the purpose is found and is then rigidly adhered to.

Another point worthy of serious attention is the quenching of the coke. As the coke is issuing red-hot from the oven it passes through a spray of water and the quenching is then finished by hand spraying. Unless the quencher is highly experienced the coke will contain either too much or too little water; in the former case there is trouble with the buyer, in the latter case the railway waggons are apt to be burnt. It is also very difficult to quench coke properly by night, since coke which appears to be perfectly quenched by day may appear red-hot by night. The adoption of some form of mechanical quencher would be a valuable improvement. In one appliance of this sort the hot coke falls into an iron basket, and is thence conveyed to a trough, where it is immersed in water for a definite time and then withdrawn. It is said to be possible to reduce the water content to under 1% regularly by this means.

The utilisation of coke breeze should be developed. At present the greater portion of this material finds its way to the colliery refuse heap. From 3 to 8% of the total coke is usually produced as breeze, the proportion depending on how the coke is handled. According to the Home Office Report on Mines and Quarries, for 1915, the total quantity of coke produced at coke ovens was 11,908,940 tons. If the breeze produced is taken at 5% this amounts to 595,500 tons. From the point of view of fuel economy it is essential that this should be utilised either for briquette making or some other purpose. If briquettes were to be manufactured from the whole of this it would incidentally provide an outlet for some 40,000 tons of pitch annually.

Apart from improvements in the coking process, very great advances are capable of being made in connection with the recovery of by-products. The recovery of by-products should start before the coking process. Large quantities of iron pyrites are washed out of the coal and these should be recovered, partly for the value of the iron, but more especially for the sulphur. No effort whatever is made to recover these. In most instances the whole of the output from a colliery passes through the washery, and large quantities of carbonaceous shale containing a good deal of coal are produced. Doubtless in many instances the shale is too high in mineral matter and too low in pyrites to make it worth treating, but with improved methods a great deal of sulphur could be recovered from this source.

The author does not profess to have gone very deeply into this particular question, but as a tentative suggestion would put forward the following two methods:—

(1) The washery refuse is treated in a specially designed producer of the Mond type. The producer gas, containing sulphuretted hydrogen, sulphur dioxide, and ammonia, is passed into the main conveying the crude coal gas from the ovens, and is treated for simultaneous recovery of ammonium sulphate and sulphur by the Feld "Polythionate" process. This process will be referred to later. The advantage of this method

would be that a large proportion of the nitrogen contained in the washery refuse would be recovered as ammonia. The diminution in the quality of the gas for heating the ovens would not be of any importance, since at least one battery of coke ovens in this country is heated by Mond producer gas having a calorific value of 140 B.Th.U. per cu. ft., and on the Continent blast furnace gas of 105 B.Th.U. per cu. ft. is used in some places.

(2) The second method consists in passing coke oven gas, after extraction of the products, over the carbonaceous shale and pyrites, heated to a suitable temperature by means of the surplus gas. The result would be the formation of sulphuretted hydrogen, sulphur, and metallic iron. The sulphuretted hydrogen would be recovered by oxide of iron purifiers. In either case the residue, if containing sufficient iron, could be sent to blast furnaces. Laboratory tests with the second method have given very encouraging results.

All coals give off sulphuretted hydrogen on carbonisation; the amount varies from 0.03 to 0.7%, by weight of coal carbonised, the figure usually being between 0.2 and 0.4%. In many instances the amount of this is such that if converted into sulphuric acid it would provide sufficient acid for the manufacture of sulphate of ammonia from the whole of the ammonia evolved. If sulphur were recovered from the pyrites as referred to above, every coal would yield sufficient for this purpose. In very few instances is anything done to utilize this sulphur.

A method is wanted which would enable the ammonia to be recovered as sulphate, using the sulphur contained in the coal to provide the necessary sulphuric acid. Not one of the methods at present suggested for doing this has come into general application. The most obvious method is to extract the sulphur from the gas by means of iron oxide, convert the sulphur thus extracted into sulphuric acid by the well-known lead chamber process, and use the sulphuric acid to extract the ammonia from the gas in the usual way. This process is not adapted to any but the largest works owing to the small amount of sulphuric acid required. A 40-oven plant will use about 15 to 20 tons of 142 Tw. B.O.V. a week. The author is informed that it does not pay to put down a sulphuric acid plant for less than about 30 tons of acid per week.

Two other processes have been devised and worked out on a practical scale, but neither has come into anything like general use. The object of each of these is to avoid the necessity for manufacturing sulphuric acid in an independent plant; future advance will almost certainly lie along these lines.

The Burkheiser process consists in extracting the sulphur from the gas by oxide of iron, burning this to sulphur dioxide and introducing the latter into the gas main. The resulting salt is a mixture of sulphite and sulphate, and this is the weak point, since contrary to expectation it was found very difficult to convert the sulphite to sulphate by atmospheric oxidation.

The Feld process, which has found some application on the Continent, consists of treating the crude gas containing ammonia and sulphuretted hydrogen with sulphur dioxide in presence of free sulphur. The recovered ammonia is thus first converted into thiosulphate and then polythionate, which is finally oxidised to sulphate with liberation of sulphur.

The whole problem bristles with difficulties and the inventor of a simple commercial process for doing this would find himself amply rewarded.

The present method of recovering ammonia is by no means the best or the most rational and much work remains to be done on this. In

the first place the system of recovering the whole of the ammonia as sulphate seems irrational. A large portion of the chlorine contained in coal is liberated on carbonisation in the form of hydrochloric acid, the amount depending on the state of combination of the chlorine, the temperature of the coke oven, and the duration of heating. As soon as the temperature in the mains is low enough this combines with the ammonia and forms ammonium chloride. Under the present system this is decomposed by milk-of-lime, and converted into a less valuable compound—ammonium sulphate.

In places where the chlorine content of the coal is sufficiently high, any ammonium chloride formed should be recovered as such. The author has done some work on this subject and recommends the following method:—The gas while still hot—about 100–130°C.—is scrubbed with a spray of water at 70°C. The water is used over and over again until nearly saturated. The solution is then concentrated further by evaporation and allowed to crystallise, any evolved gases being led into the gas main. The mother liquor is diluted with water and again used for washing the gas. If care is taken that the tar is properly separated from the liquor and if only a moderate quantity of crystals is obtained at each evaporation, a reasonably pure product may be manufactured without any necessity for recrystallisation. When the accumulation of other salts in the liquor gets so great that the chloride is contaminated, the liquor is sold to some works having a lime still and the cycle of operations recommenced with fresh water.

In an actual experiment conducted on a works scale, the liquor obtained had the following composition:—

	grms per 100 c.c.
Ammonium carbonate.....	0.22
" sulphide	traces
" cyanide	0.10
" sulphate	nil
" ferrocyanide.....	9.52
" chlorine.....	

Without doubt the ammonium chloride content could have been raised to three times this amount by longer circulation.

On evaporating a portion of this in the laboratory the chloride obtained had the following composition:—

	Salt obtained.	Theoretical.
Ammonia as NH_3	30.80	31.85
Chlorine as HCl	67.89	68.15

The salt was of a grayish-white colour.

The recovery of ammonia as chloride is practised in a few works, but there is no reason why it should not be adapted to every existing plant. The recovery of the hydrochloric acid evolved in the distillation of coal could in this way be easily and completely effected and at the same time yield considerable profit.

In the author's opinion the recovery of the tar and ammonia from coal will ultimately take place somewhat on the following lines:—

The hot gas from the ovens will be allowed to cool to a temperature of about 120°C. and will then be sprayed with hot water at 70°C. This will extract ammonium chloride and the tar fog. The author finds from practical experience that it is necessary to provide means whereby the gas entering the chloride extractor may be either

warmed or cooled in order that the temperature may be under complete control.

After spraying with hot water to recover ammonium chloride, the gas containing sulphuretted hydrogen and ammonia will pass on to an apparatus where sulphate of ammonia will be recovered direct. As has been mentioned before, one of the most promising lines of research is the discovery of some economical process which will effect this.

Another compound which has been neglected is naphthalene. The market for this product is growing, and will increase even more in the future with the development of internal combustion engines using this as fuel. At some direct recovery plants there has been trouble owing to naphthalene blocking up the mains; this has necessitated the installation of naphthalene recovery apparatus. The method has been to spray the hot gas leaving the saturator with cold water. This treatment is not possible with any other type of plant, as the essential feature is sudden cooling. In other types of plant the naphthalene is absorbed by creosote oil when extracting benzol. In order to recover the naphthalene, another fraction is taken after the benzol has been driven off from the creosote oil by distillation, and this is allowed to cool in pans and the naphthalene fished out. The original intention of this process was to prolong the life of the benzol scrubbing oil by preventing it from becoming unduly viscous, and as far as this is concerned it has succeeded admirably. As a process for recovering naphthalene, however, it is very inefficient. Only a small proportion of the naphthalene taken up by the oil is recovered in the fraction distilled, and it would not be economical to distil to, say, 230° C. simply in order to recover naphthalene. The oil takes up more and more naphthalene until a point is reached when it is in equilibrium with the gas. It is clear from a consideration of the physico-chemical factors involved that the naphthalene absorption must be very inefficient. A process is wanted for carrying this out on more efficient lines.

The method of washing the crude benzol is open to improvement. At present the benzol is washed first with 5 to 8% of its volume of sulphuric acid (D.O.V.) in two washings, then with water, followed by caustic soda and more water. This takes considerable time and attempts are being made to make the washing of benzol continuous. In one such plant the benzol vapours from the still are passed through hot acid and caustic soda. In another plant the liquid falls down a series of tubes in which it is treated with the washing reagents. Whether either of these processes will prove commercially workable has yet to be seen. Some system of continuous washing is, however, very desirable.

No attempt is made to recover the phenol, pyridine, or thiophene washed out of the benzol, and in view of the large quantity of benzol dealt with on coke oven plants this would be a useful step forward. Under present conditions of working it would probably not pay. The phenol content of 65% benzol is usually under 2%. Much of the pyridine present in the gas is taken out by sulphuric acid in the saturator; and until new uses are found for thiophene it will not be worth recovering on coke oven plants. The recovery and utilisation of these substances is a matter for research.

The present system of recovering 65% benzol is not the one calculated to give the best results. It is found in practice that by manufacturing benzol of 55% strength there is a very considerable increase in the amount of toluene recovered. It seems, therefore, preferable to recover benzol of much lower strength than is the case at present, and to wash this for phenol. Occasionally the creosote oil should be distilled up to, say, 210° C.,

and the half-spent caustic soda which has been used for washing the benzol used for the first washing of this creosote fraction. In this way it may be found possible to recover considerable quantities of phenol. With the price of 60's carbolic at 3s. 4d. a gallon this should be well worth considering.

It would be very advantageous if a system could be found whereby the carbon bisulphide could be recovered from the gas before taking out the benzol. Carbon bisulphide is not usually recovered on coke oven plants, being regarded merely as an objectionable nuisance. This is not easy to understand, as a good price is obtainable for it. Benzol will frequently contain 5% of this compound.

In all probability the coke oven plant of the future will not stop at the recovery of crude 65% benzol or washed 90% benzol. It will manufacture pure benzene, toluene, and xylene, and probably also nitrobenzene, nitrotoluene, aniline, toluidine, and possibly pure naphthalene, together with α - and β -naphthol. The manufacture of the raw materials for dyes would be more rationally carried out on coking plants than at the dye works; and it would leave the manufacturers of dyes more opportunity to concentrate on the production of colours if coke oven plants would undertake the manufacture of these raw materials.

A necessary step before this ideal can be reached is the training of qualified men capable of taking charge of such works, and coke oven managers and chemists must be more highly trained in the future than they have been in the past.

The utilization of the surplus gas from regenerative coke ovens is a matter which is now receiving considerable attention. The author recently pointed out (*Trans. Inst. Min. Eng.*) that the surplus gas evolved from by-product regenerative coke ovens is equivalent to over a million tons of coal per annum. In a great number of cases this gas is allowed to burn at a blow-off pipe in order to get rid of it. It would be possible to transfer this gas to neighbouring towns by means of high pressure mains, as is done in the case of natural gas in the United States. There is, of course, also the possibility of using it in gas engines to generate electricity, which could then be distributed over a large area.

It also seems possible that the mixture of unsaturated hydrocarbons, methane, and hydrogen in the gas may be found capable of being transformed into valuable products either by chemical or physical means.

ADDENDUM.

With reference to the possibility of using coal gas for the synthetic production of valuable compounds, alluded to in the last paragraph, reference may be made to the paper on "*Production of the lower chlorides of methane from natural gas*" by W. Bedford (*J. Ind. Eng. Chem.*, 1916, 8, 1090—1094; see this J., 1917, 46). By subjecting a mixture of chlorine and natural gas, in a chamber containing blocks of ice, to the action of light from the white flame arc, a heavy liquid was obtained beneath the water produced by the melted ice; this liquid consisted of methylene chloride, 35%; chloroform, 35%; carbon tetrachloride, 5%; chloroethanes, 20%. A portion of the product, amounting to about 14% of the total, remained soluble in the water, and consisted of methylene chloride, 61%; chloroform, 28%; carbon tetrachloride, 1.5%; and chloroethanes, 6%. Two hundred and fifty cubic feet of the natural gas yielded several gallons of the mixed chlorides.

DISCUSSION.

The CHAIRMAN welcomed the references made in the paper to problems awaiting solution which

might guide research chemists who were wanting to give their science a technical application. The importance of refractory materials to the carbonising industries was coming to receive recognition and a laboratory for this study was being specially staffed and equipped at the University of Leeds in connection with the Department of Coal Gas and Fuel Industries. The wide differences in properties between the ordinary silica brick and vitrified silica was a simple example of how much depended on other things than chemical composition and how much work lay before them. The author's reference to the use of the sulphur contained in coal as the source of the sulphur in ammonium sulphate called attention to one of the most important questions.

Mr. C. P. FINN remarked that the processes of carbonising coal for "town gas" on the one hand and for the production of metallurgical coke on the other had much in common and that any advance in either branch of the industry had its influence on the other. This being the case, he thought that the success of the modern continuous or semi-continuous vertical gas retort should stimulate coke oven constructors to produce a similar type of plant, with a sealed inlet for the coal and the utilisation to the full of the heat of the discharging coke, thus placing at the user's disposal a dry product. He knew that there were objections, viz., the absence of a "rest period" and the difficulty of charging compressed coal, but in his opinion these were not insuperable obstacles. Concerning the recovery of by-products he drew attention to methods proposed by Feld, Purves, and others for the fractional separation of tar products within the condensing and washing system. Referring to ammonia recovery, he was pleased to hear that Professor Cobb's recovery process would soon be working on the large scale with Mond gas. The possibilities of competition of synthetic ammonia processes, backed by large Continental syndicates, should stimulate research to obtain greater yields of ammonia from coal. The by-product coke oven plant of to-day was no longer a mere adjunct to a colliery as was the old bee-hive oven, but a complex chemical works using a raw material of unknown constitution. It was quite outside the scope of the average colliery manager and engineer, and required for its control men who combined a sound scientific training and the general experience gained only in a works. Such a man must not be a mere "handler of men," but able to direct his assistant staff in the prosecution of works research into the many problems that arise from time to time.

He was optimistic as to the further development of chemical manufacture on coking plants, as probably no other industry had at hand such sources of power and cheap, clean, and high quality fuel.

Mr. W. McD. MACKEY said that the author had mentioned many important points in connection with by-product coke oven practice, some of which had already engaged the serious attention of chemists. He had said nothing about low temperature carbonization, and this he (Mr. Mackey) thought was likely to prove a very fruitful field of research in the future; a low temperature coke for domestic use would soon be on the market in quantity, and he understood that it was only because of difficulties raised by the war that it was not already on the market. Mr. Mackey considered that the solution of the difficulty of smoky atmospheres in towns would be largely solved by the provision of a soft coke, clean to handle, and containing sufficient volatile matter to burn readily. He was doubtful if the recovery of sulphur from colliery refuse would be profitable. The mere handling of material with comparatively little sulphur in it was in itself a serious difficulty. As to coke breeze, his experience did

not agree with that of the author, viz., that it was difficult to market; and certainly he did not know of its being put on the dump. He was dubious as to the advantages of automatic quenchers. High pressure water under the direction of an intelligent workman he considered better. The point was to water so as to leave the coke warm enough to drive off the water remaining from the quenching; though in practice they might expect about 1.5% of moisture in well-quenched by-product coke.

Dr. L. GORDON PAUL asked how it was suggested to recover the carbon bisulphide.

Mr. HARMER said that the carbon bisulphide was usually recovered by fractionation from the crude benzol, and that much could be done by fractional separations at low temperatures.

Mr. FOXWELL said in reply that, as the Chairman had pointed out, the physical properties of the silica brick were very interesting. Quartz on heating changed into other crystalline forms, and about 80% of the free silica in a brick consisted of cristobalite. He suggested that in connection with salt corrosion it might be that only one of these crystalline forms was attacked. He had purposely not mentioned the fractional condensation of tar as this would require a complicated plant and highly skilled supervision. It seemed more economical to proceed as is done to-day.

With regard to the vertical oven, he remembered that in the early days of vertical retorts great trouble was experienced in connection with the refractory materials of which they were constructed. Probably similar trouble would be met with in connection with a vertical coke oven, and work on refractory materials must precede any successful attempt in this direction. The vertical oven would possibly be a sound proposition for uncompressed coals, but what of coals which required compressing? He was not in favour of low temperature carbonisation, since the tar produced, being mainly paraffinoid, would only be of use for fuel, and moreover the yield of sulphate of ammonia was very low as compared with that from the high temperature process. The consequence was that the solid fuel produced (intended for household consumption) would have to be sold at a price higher than that of coal if the process was to be a financial success. It was certainly his experience that coke breeze—by which he meant coke passing through, say, a 1 cm. mesh—was thrown away. Published figures dealing with a plant at an English gas works had shown that it was possible to run a coke breeze briquetting plant at a good profit. American coals, generally speaking, required more heat for their carbonisation than English coals.

Iron and Steel Institute.

The following are abstracts of some of the papers read at the meeting of the Iron and Steel Institute held on May 3rd and 4th:—

PROPERTIES OF THE REFRACTORY MATERIALS USED IN THE IRON AND STEEL INDUSTRY. By C. Johns.

Available materials. With the exception of carbon, and its compounds with silicon, which have a limited application, the available refractory substances are chiefly the oxides, SiO_2 , Al_2O_3 , CaO , MgO , Cr_2O_3 , or mixtures of these with oxides of iron, K_2O , Na_2O , and traces of other substances, regarded as impurities, some of which may function as catalysts. The materials available are therefore strictly limited; they never occur in a state of purity in nature. Their manufacture into refractory products involves in many cases grading, agglomeration or bonding, and final heating to a

temperature that varies according to the purpose for which the product is intended and the functions it has to perform. The problems that arise are not solved by a knowledge of the properties of the compounds mentioned; they are complicated by the presence of impurities and the varying nature of the bonding material employed. The final products, as delivered to the user, are always mineral aggregates, often of great complexity. They possess no fusion point, but rather a range during which softening, at first inappreciable, at last, with increasing temperature, causes the material to fail to perform its functions. The constituents have varying melting points, and during heating they invert and new phases appear. Some inversions, involving serious volume changes, should be completed during manufacture, but often are not. The temperatures required for such changes are rarely known, and even when they are known as a result of experiments under laboratory conditions, it does not follow that they apply to manufacturing processes. The most urgent need at present is for an expression, in terms of scientific precision, of the most successful practice in manufacturing the refractory products and of the physico-chemical changes which take place when they are used.

Tenacity and compressive strength at ordinary temperatures are valuable only in so far as they permit the refractory products to be transported and enable them to withstand the structural stresses to which they are exposed when used. It is when the material is exposed to high temperatures that the value of these properties becomes most important. The abrasion caused by the movement of solid substances while in contact with their heated surfaces is important, while the erosion caused by the passage of dust-laden gases at high velocities becomes serious in time. Little or nothing is known of the conditions that favour or retard abrasion and erosion. High tenacity, which in most cases would mean that of the bonding or of the most fusible constituent, is most probably the desired property. It is the surface exposed to the highest temperature which suffers, for it is the one that is in contact with the moving solids, liquids, or gases. Compressive strength is rarely a cause of failure, for the bulk of the refractory material is at a lower temperature than the face and therefore less affected. There is, however, urgent need for accurate determination of the two properties under discussion at wide ranges of temperature for the more important materials under both oxidising and reducing conditions.

Corrosion changes. Not less important than resistance to high temperature with concurrent abrasion and erosion is resistance to the corrosion caused by slags and gases. The effect of acid slags on basic refractories and of basic slags on acid refractories are familiar, and there is marked corrosion of the silica bricks in the gas ports and uptakes in open-hearth furnaces, due to the alternating passage of oxidising and reducing gases with the resulting formation of fusible silicates. A factor conducive to rapid corrosion in the last case is the absence of large particles of silica in the bricks employed and the presence of excessive pore spaces. Here again little has been published and few observations recorded. The effect of the alkalis found in certain coals on the refractories used in coke-oven construction is serious, and here too little is known as to the real nature of the destructive influences at work.

Volume changes. Apart from the fact that volume changes may cause disintegration, abnormal expansion causes structural difficulties, while contraction may be even more undesirable. In the case of coke-ovens the retention of gas-tight partitions is absolutely necessary, and this involves the use of a refractory material which does not undergo appreciable volume changes, i.e., a mixture of substances with volume changes of opposite

sign, viz., clay and silica. But while the contraction of the burnt clay is fairly regular with increased temperatures, quartz has an inversion point at which it becomes tridymite. In the presence of certain compounds this inversion takes place at a temperature lower than that at which coking is carried on. In their absence the inversion is retarded and does not take place until a temperature higher than that usual in coking practice is attained.

Heat conductivity. If the refractory materials used possess a fusion point or softening range higher than the maximum temperature to which they are exposed, it would in most instances be desirable that they should be non-conductors of heat, for radiation losses would then be at a minimum. More often the prevailing temperatures approach and sometimes exceed that at which fusion or softening occurs. In those cases it is necessary to encourage radiation from the surface farthest removed from the heated surface, in order to cause a steep temperature gradient from the heated to the cooler face. In special cases cooling devices are necessary to prevent the rapid destruction of the material employed. The melting of steel in crucibles and the coking of coal are instances where a refractory material with good heat conductivity is required.

Texture and porosity. The relative size of the grains employed, the extent of the surface exposed by the more resistant constituents to the others used as bond or matrix, are most important factors in contributing to the ability of the material to perform useful service. Another point of some importance is the influence of mass in promoting or retarding inversions. Some of these inversions take place almost instantly once the critical temperature has been reached, but with others marked hysteresis occurs. Porosity must always occur when the refractory material is composed of more than one constituent, and where their chief volume changes are dissimilar or occur at different temperatures. Little is known of the effect of porosity on the properties of refractory materials. That the pores encourage the deposition of extraneous substances in the interior of the bricks, and that they render the structure permeable to gases, is of course obvious.

Stresses caused by temperature changes. The stresses caused by temperature changes are due to the volume changes which take place during heating. If the refractory material happens to be a good conductor of heat these are not serious, unless one face is rapidly heated and the distortion produced exceeds the tenacity of the material. The remedy available is to avoid rapid temperature changes, and whenever possible to raise the temperature of the material during the burning stage of manufacture well above that at which the inversion to which the principal volume change is due should take place, and to hold it at that temperature long enough for the inversion to be completed. The "spalling" of magnesite bricks which sometimes occurs has been thus explained, and it is certain that the excessive expansion of silica bricks would be avoided if the manufacturer could ensure the completion of the quartz-tridymite inversion during burning. Despite the considerable advances in our knowledge of the inversions of silica made recently, their bearing on the problems that face the manufacturer is not yet sufficiently clear.

Need for further research. The first step is to prepare specifications for the most important refractory products expressed in terms capable of precise measurement or description, basing the specification on the best current practice. These specifications should be the starting point of systematic research which should cover, not only the problems that occur during manufacture, but the occurrence in nature and characteristics of the

raw materials. Their concentration and purification, proximate and ultimate analysis, mineralogical description and thermal analysis are all points on which additions to our present knowledge would be of great value. But the refractory materials are so complex, and the problems involved are so difficult of direct attack, that any contribution to our knowledge of the properties of the pure minerals, or of the impure aggregates which are used in practice, would be welcomed even if their immediate application did not happen to be possible.

The following schedule of the requirements of the iron and steel industry, indicating the most pressing problems affecting the use of refractory materials, is suggested:—*Coke-oven bricks.* Description as complete as possible of the foreign clays found suitable and of the British clays that resemble them. Investigations of the cause of failure of coke-oven bricks. Influence of texture and firing temperatures on their durability in service. *Blast-furnace bricks.* Tenacity at high temperatures. Causes of disintegration. Influence of texture and mineralogical character of original clays. Description of the available clays. *Carbon bricks.* Texture and bond. Influence of these on tenacity and crushing strength at high temperatures. *Magnesite bricks.* Texture and bond. Firing temperature. Thermal analyses of magnesite from various sources. Properties of the burnt brick. Thermal analyses with quenching from high temperatures. Substitution of dolomite for magnesite for brick making. *Silica bricks.* Texture, bond, and firing temperature. Mineralogical description of the fired brick. Thermal analyses of brick with quenching from high temperatures to determine actual constitution under working conditions. *Nozzles of casting ladles.* Cause of erosion. Influence of texture and firing temperature on resistance to erosion. Influence of casting temperatures and quality of steel on erosion. Use of new materials. *Chromite bricks.* *Bauxite bricks.* *Zirconia and other rare earths.* *Fused magnesia and lime.* Investigation of mode of occurrence of raw material in nature. Description and determination of properties of the pure minerals. Methods of concentration and purification. Bonding and preparation as refractory products. Properties of the finished product.

PENETRATION OF THE HARDENING EFFECT IN CHROMIUM- AND COPPER-STEELS. By L. Grenet.

Four chromium-steels containing C 0.31–0.59, Cr 1.46–1.82, and Cu 0.00–4.14%, and eleven chromium-nickel steels containing C 0.34–0.62, Cr 0.41–1.84, Ni 1.60–3.93, and Cu 0.00–4.0% were investigated. The transformation on heating occurred below 775° C. in every case; and the Brinell hardness of small pieces quenched from 790° C. was 600 and upwards. Copper was found to increase the depth of the hardening effect but to exert no other useful influence on the properties of the steels. The influence of copper was more limited than that of nickel; the chromium-nickel steels high in nickel became hardened by very slow cooling, but none of the chromium-copper steels possessed this property. By the use of copper, nickel, and chromium together, semi-hard steels were obtained which could be hardened by air-cooling in fairly large pieces and yet softened by the ordinary methods employed for carbon steel.—W. E. F. P.

STEEL INGOT DEFECTS. By J. N. Kilby.

The defects occurring in ingots up to 3 tons in weight are considered under the following headings. *Pipe.* Moulds wider at the top than at the bottom

are conducive to minimum pipe; and considerable economy is effected by the use of refractory feeder heads, even for ordinary steels. "*Ocluded slag*" in acid open-hearth steel results from oxide of iron formed during the melting of the charge or introduced by erratic feeding of ore; it may be minimised by melting the charge quickly under conditions producing a slag and bath of suitable composition and consistency. In the author's opinion, the whole charge should have an available silicon content of 2%, the difference between this figure and the silicon content of the pig iron and scrap being added in the form of slag. The use of limestone and the period at which it should be added are of the greatest importance in acid open-hearth practice; slags containing lime possess greater fluidity than those free from this constituent, and having also a higher silica content (62% as against 50%), absorb suspended particles of "slag" from the bath more readily. "*Lapping*," or folding on the surfaces of ingots may result from pouring bottom-cast steel at too low a temperature or speed. Contrary to the view held by many steel makers, the author is of opinion that cavities or splits in rolled or forged bars do not result from lapping in the ingots. The effects of spasmodic teeming, resulting from the use of a comparatively large nozzle in the ladle and a small number of ingots per bed, are often wrongly ascribed to lapping. *Fluxed fireclay.* All bottom-poured steel is liable to contain fluxed runner brick or partly fused pieces of fireclay jointing. The presence, in ingots, of extraneous matter of the latter kind may be minimised by the use of a suction ejector down each mould and a "trumpet" pipe immediately before casting. *Cracks.* In acid open-hearth ingots, are mainly cross-sectional and vertical and occur principally at the corners of square or octagonal ingots in the latter case. A chart is given showing the comparative margin of safety in casting ingots free from cracks under varying nozzle-sizes and capacities per bed; and tables showing (1) the teeming speeds at which a number of top-poured ingots of various sizes, free from cracks, were produced, and (2) the relative proportions of cracked bars from top- and bottom-poured ingots produced at various teeming speeds.—W. E. F. P.

CEMENTATION [OF IRON] BY GAS UNDER PRESSURE. By P. C. Langenberg.

Experiments on the carburisation of "Armco" iron (C 0.01%) by illuminating gas and acetylene at various temperatures and pressures were made in an electrically-heated pressure and vacuum tube-furnace of special design. The results are detailed in tables, curves, and micrographs. Owing to the deposition of carbon in the cooler parts of the tube, no carburisation was effected by illuminating gas at 900° or 1000° C. under atmospheric pressure; and for a similar reason the cementation of iron in acetylene at the same temperature and pressure occurred only when the flow of gas exceeded 2.75 litres per hr. In acetylene at atmospheric pressure, and under equilibrium conditions obtained by the use of carbon in the tube, the depth to which the iron was carburised in 4 hrs. at 980–985° C. increased from 1.25 to 1.75 mm. as the rate of flow of the gas increased from 0 to 3.25 litres per hr.; while at a constant rate of flow a sudden increase in carburisation occurred when the temperature was raised from 890 to 900° C., the region of the γ – β allotropic change in pure iron. With illuminating gas under similar equilibrium conditions, the rate of flow being 5 litres per hr. and the time of exposure 3 hrs., the following depths of carburisation were obtained:—0.3, 0.6, 1.0, and 1.6 mm. at 810°, 910°, 950°, and 1025° C., respectively, under

atmospheric pressure; 1.0, 1.0, 1.1, 1.25, 1.30, and 1.40 mm. at 910° C. under pressures of 25, 33, 45, 65, 90, and 115 lb. per sq. in., respectively; 0.5, 0.45, 0.45, and 0.45 mm. at 805°—810° C. under pressures of 40, 65, 90, and 115 lb. per sq. in., respectively; 1.8, 2.25, and 2.6 mm. at 990°—995° C. under pressures of 26, 45, and 75 lb. per sq. in., respectively. No carburisation was effected below 720° C. with either gas, and the γ - β points were found to mark a sharp break in the carburisation curves for both.—W. E. F. P.

CASE-HARDENING OF IRON BY BORON. By N. Tschischewsky.

A hole was drilled in each of two cubes of soft iron (C 0.12%) from the centre of one face to about the centre of the cube. The hole in one cube was filled with fine amorphous boron, the other with finely-powdered ferro-boron (B 19%). The holes were tightly closed by stoppers of the same kind of iron pressed home by hydraulic means. The specimens were heated for two hours to 950° C. in a silica tube evacuated with a mercury pump. They were then cut longitudinally and polished. The boron had penetrated to the depth of 1 mm. It was ascertained that cementation by ferro-boron is quicker than by amorphous boron. The hard, white surface layer consisted of compact boric pearlite having a twin crystal structure; the edges of the layer contained a sub-eutectic alloy of ferrite-pearlite, the ferrite containing the boron in solid solution. Case-hardening at a lower temperature gave an alloy containing less boron.—W. R. S.

DETERMINATION OF THE LINE SE IN THE IRON-CARBON DIAGRAM BY ETCHING SECTIONS AT HIGH TEMPERATURES IN VACUO. By N. Tschischewsky and N. Schulgin.

The preheating of sections of iron-carbon alloys, prior to etching by gaseous reagents, does not give trustworthy results owing to the decarburising action of the gases used. In the present experiments the sections were heated *in vacuo*, and chlorine was used as etching medium. Two points on the cementite line were thus determined, by studying photomicrographs of two alloys containing C 1.25 and 1.505% and heated to different temperatures at intervals of 10° to 15° C. The mean of the interval within which the disappearance of cementite in the chilled specimens was observed was taken as the transition point:—

C %	Interval.	Mean.
1.25	875°—890°	883° C.
1.505	1005°—1015°	1010° C.

The proximity of these points to the straight line between the points E and S in the iron-carbon equilibrium diagram justifies the supposition that the line SE is a straight line.—W. R. S.

INFLUENCE OF SURFACE TENSION UPON THE PROPERTIES OF METALS, ESPECIALLY IRON AND STEEL. By F. C. Thompson.

The author replies to criticisms directed against his theory correlating the properties of metals, especially the elastic limit, with the effect of surface tension, which is supposed to act at the crystal boundaries, or between the crystalline phase and the intercrystalline amorphous modification (this J., 1915, 620); the available evidence in favour of the theory is reviewed and extended.

—W. R. S.

NOTES ON SOME [STEEL] QUENCHING EXPERIMENTS. By L. H. Fry.

Two locomotive driving axles and a small test-piece were quenched in air, water, heavy and light oil, and different strengths of a cutting compound (mineralised lard oil and soft soap) dissolved in water. It was found that fairly accurate information as to the quenching properties of a medium (*i.e.*, cooling rate per sq. in. of surface) can be obtained with small objects. Regarding the physical properties of quenched steel, these are determined by the rate at which the heat is lost, not per unit of surface, but per unit of weight; the rate of quenching depends chiefly on the size of the object, less on the nature of the quenching medium. Hence the only scientific method of defining heat treatment is to give the rate of temperature loss over a given range; expressions such as "water-quenching" and "air-cooling" are quite indefinite.—W. R. S.

Industrial Notes.

CELLULOSE AND CHEMICAL INDUSTRY (1866—1916).

Abstract of a Lecture delivered at the Royal Institution on March 2, 1917.

BY C. F. CROSS.

The chemical industrial developments of cellulose are characteristic of the modern age, which in this section of technology dates from 1866. At this date the necessity of meeting the progressive consumption of paper by a supply of original raw cellulose material led to the introduction of esparto grass by Thos. Routledge, and to the investigation of wood material as the most massive form and source of cellulose. As the result of the pioneer work of an Anglo-Swedish group, of which the late C. D. Ekman was a prominent member, and for which his English collaborators (Messrs. Thomson, Bonar and Co., and George Fry, of Berwick-on-Tweed) supplied the means, the business organisation, and a considerable contribution to the technical and scientific basis of investigation, the wood pulp (cellulose) industry was launched.

It was considerably developed by the technical improvements introduced by our countryman, Edward Partington, now Lord Doverdale, who also brought to bear on the industry organising and business capabilities of a high order; the results, which have been cumulatively successful, are known to the world.

In these processes of resolving raw material into paper-maker's "pulp," the cellulose, as the chemically inert or non-reactive basis of the raw materials, resists the severe treatments required to attack the non-cellulose components. The esparto compound celluloses are resolved by alkaline treatment (caustic soda solution at 120°—130°), the wood substance (ligno-cellulose) by treatment with acid compounds (disulphides) in solution at 140°—160°.

The soluble by-products, derivatives of the non-cellulose complex, amounting in either case to 50 per cent. of the original raw material, are in effect waste products. In the case of the esparto they are burned incidentally to the recovery of the soda; but the "wood liquor" by-product is still in the main a waste, and a colossal one.

The "positive" chemical technology of cellulose is necessarily based upon its reactivity, and the industries which exploit the reaction changes of cellulose are of widely divergent character; those of Group A are based upon reactions of decompo-

sition; those of Group B are based upon the properties of synthetical derivatives.

Of Group A, the resolution of cellulose into sugar (dextrose) by acid hydrolysis is the basis (1) of a process for the preparation of industrial (ethyl) alcohol from wood, and more economically from wood wastes. According to our latest information, the technical difficulties presented by this apparently simple process have been so far overcome that the alcohol is produced on the large scale at a cost of 2½d. per gallon, exclusive of the small cost of the waste wood material. Under these most favourable conditions, however, the yield of alcohol is only 5 per cent. of the weight of the wood substance, or say 8 per cent. of its cellulose content, leaving therefore a very large item of final waste to the debit account of the chemist.

(2) Sawdust, or other wood waste, fused—i.e., heated at high temperatures—with the caustic alkalis is destructively oxidised, and the main product of the oxidation is oxalic acid; this process is in effect the main source of the acid, as an industrial product.

(3) Waste wood subjected to destructive distillation in closed retorts is resolved into gaseous and volatile liquid products, with a solid residue of charcoal or pseudo-carbon. The liquid products contain acetic acid, acetone, and methyl alcohol as chief constituents, and have been the main source of supply of these chemical individuals, which, as reagents especially, are indispensable in modern chemical industry.

In this direction, however, cellulose material and its wasteful treatment by destructive distillation are being supplanted by a direct and controlled synthesis from calcium carbide, acetylene being quantitatively transformed into acetaldehyde, and this into acetic acid. In this new industry the pioneers in this country are the British Cellulose and Chemical Manufacturing Company, Spondon, Derby.

(1) Cellulose treated in full contact with oxygen is burned with the familiar flame combustion; but from all the natural structural forms there is a residue of inorganic matter (ash) which when present in important proportion preserves the general structural details of the original. This intimate combination of cellulose with inorganic matter is a characteristic property of colloids of which cellulose is the prototype. It is the basis of innumerable processes incidental to the dyeing and colouring of cellulose fabrics and tissues. But the production of a combustion skeleton for utilisation as an industrial product is a modern and noteworthy realisation of a primary cellulose quality "strong even in death."

The familiar incandescent gas mantle is the skeleton of a textile material impregnated as such, or as we may say, "in the flesh," with colloidal thorium and cerium oxides, and afterwards cremated.

Of the cellulose industries of Group B, those (1) based on the nitric esters are of preponderating importance, for they include the production of the modern military explosives and they connote developments in pure and applied science peculiarly characteristic of the age. Cellulose nitrate not only fulfils the ideal of chemical effect, i.e., total conversion of solid into gaseous matter, at maximum increase of volume (or pressure), further increased by the temperature of combustion, but is a stable form of this high chemical potential, and further owing to its colloidal plastic properties can be moulded into any desired form and is therefore able to meet the most exacting specification of ballistic requirements. There is no doubt that mankind is directly indebted for its "smokeless" powders and the basis of the vast developments of modern military power to the pioneer work of Alfred Nobel and his collaborators.

The lower degrees of "nitration" of cellulose are represented by products which are the basis of "celluloid," and the celluloid industries connote the production of a large number of familiar objects both useful and ornamental, and a progressively increased production from the date of the pioneer work of the American inventor, Hyatt (1869). (See this J., 1914, 225.)

Celluloid realises a very high order of plasticity, and it is this structural potentiality which enables it to maintain its industrial leadership in spite of its disadvantages of high inflammability frequently and tragically manifested.

(2) The analogues of the nitric esters, are the acetic esters of cellulose derivatives, which are necessarily colloids with plastic capabilities, water-resistant as are the nitrates, and with a higher order of resistance to heat (unchanged at 200 °C.), and the ordinary inflammability of organic substances. Important uses of the cellulose acetates already established are: (a) in aeroplane construction, for treating to render taut and impermeable the textile fabric which constitutes the air-resistant surface of the wings; (b) in the form of film, as the "emulsion-film" support in photographic work, notably for the preparation of the continuous cinema picture; (c) for a varnish for metallic surfaces, and notably for electrical insulation and applications which depend upon exceptionally low inductive capacity.

In the above brief account of the cellulose nitrates and acetates there is the implicit suggestion of the production of artificial textile threads by drawing the solutions of these bodies through orifices of suitable form and dimensions such that after removal of the solvent liquid the re-solidified and structureless ester constitutes a cylinder of hyaline material of uniform diameter.

The industrial production of artificial threads, and notably of the "silk" or lustra cellulose, we owe to the pioneer enterprise and purposeful tenacity of a French technologist, H. de Chardonnet. But cellulose nitrate as *matière première* has many and obvious defects: hence the alternative plastic forms or derivatives of cellulose have progressively displaced the original industrial product, which had a brilliant career of success in the early years of this century.

There are three main rival processes of which the underlying principles are common. They are expressed in the stages or phases of the process:—

(1) Cellulose is transformed by reaction into a synthetic derivative—dissolved as such to an 8 per cent. solution (calculated as cellulose), filtered and continuously projected, or drawn through fine tubes or orifices, into a solidifying or setting medium.

(2) The thread as a unit filament (monofil, crin, crinole), or multiple group of twisted filaments (artificial silk), is a cellulose ester or other derivative, and is chemically treated to remove combined groups, or impurities as by-products of decomposing reactions; the thread substance is cellulose, reappearing as such after the cycle of changes.

The three cellulose derivatives on which these important industrial processes are based are: (1) The nitric esters; drawn or "spun," as ether-alcohol solution (Chardonnet process).

(2) The ammonia-soluble cellulose-hydrate-copper-hydroxide compounds (Cuprammonium process).

(3) The xanthic or sulpho-carbonic ester, synthesised in two stages: (a) mercerisation of the cellulose; (b) combination of the alkali cellulose with carbon bisulphide, and solution of the product in water (Viscose process).

Of these the Viscose process is now predominant by reason of its advantages, technical and economic. It will be noted that the material "elements" of the industry are cellulose, common salt, carbon and sulphur, than which no simpler terms could be devised, even as an *a priori* proposition.

Of other industrial applications of the Viscose process, the production of transparent film in continuous length is a variation only of the process above described, the liquid viscose being drawn through a controlled adjustable slit of 1.5 m. width, into a setting solution or precipitant, which converts it at once into the solid state, but retaining 80 per cent. of water. This hydrated product is purified by successive treatments, and is finally dehydrated and dried with a shrinkage of 33 per cent., the 1.5 m. of hydrated xanthate, as first precipitated, being reduced to a width of 1 m. in the finished cellulose film.

This is a noteworthy achievement in chemical engineering, and is entirely due to the inventive prescience of the personnel of the Société Française de la Viscose, especially to MM. L. Naudin and J. B. Brandenberger. It is a pleasant duty to recognise technical pioneer work of so high an order.

In addition to these main applications there are many other uses of the reactions involved in the Viscose cycle. Thus "mercerisation" of cellulose is an application of the interaction of cellulose (textiles) and caustic soda, to produce lustre effects and finishes upon cotton goods. The structural changes of yarns and cloths determined by these reactions were investigated by John Mercer at a period which long antedates our half-century of progress. To Mercer's anticipations there succeeded a long incubation period. A few discoveries of minor import in this field then revived interest in the major product; the alkali cellulose of the Viscose cycle and "mercerised goods" became a textile market of first note and importance.

DEVELOPMENT OF JAPANESE CHEMICAL INDUSTRIES.

Some of the recent developments of chemical industries in Japan are described by Prof. H. Nishida in the first issue of a new periodical, "The Chemical Technology," which is to be issued monthly (subscription price 3.36 yen per annum).

In regard to the manufacture of dyes, it is stated that many plants have been established since the outbreak of the war, in the endeavour to produce the 12,000,000 lb. of dyes required in Japan annually, but most of them have had to close owing to shortage of capital and lack of expert assistance. The Japan Dyestuff Manufacturing Co., which is subsidised by the Government, and to which reference has already been made (this J., 1915, 954; 1916, 37) has for some time past been working successfully, producing aniline oil and salt, phenol, Orange H., Benzo Purpurine 4B, Fast Red A, and Congo Red. A number of direct, basic, and sulphur colours will shortly be produced, and it is also intended to manufacture synthetic indigo. The Tokyo Gas Company and the Mitsui Mining Company have also met with considerable success, and are producing dyes on an industrial scale.

The manufacture of medicinal chemicals has also received a great deal of attention, and a number of compounds are being produced for the first time in Japan, including morphine hydrochloride, salicylic acid, bismuth compounds, atropine sulphate, chloroform, codeine, guaiacol, heroin, and tannin.

The wood distillation industry received a great impetus owing to the increased prices. Acetic acid manufacture had already been placed on a sound basis, and the works were able to extend their output to such an extent that they produced over 3,450,000 lb. in 1915, of which nearly 1,470,000 lb. was exported. Importations of calcium acetate from America having ceased during

1915, the manufacture of this product in Japan has increased considerably. Imports of formaldehyde into Japan amount normally to about 1,000,000 lb. annually, mostly from America and Germany; these supplies are not now available and steps are being taken to manufacture sufficient to fill the local demands, at any rate. The output of methyl alcohol has also been increased and the process of making it improved. Formerly only about 300,000 lb. was produced annually.

The consumption of glycerin in Japan amounts to about 1700 tons per annum, of which 1000 tons was imported, mainly from England, America, and Germany; several plants, one of them working under Government subsidy, have recently been erected, and it is expected that the supply will shortly meet the demand.

Japanese glass manufacturers have been doing greatly increased business, especially with India and Australia. The over-production which took place in the celluloid industry prior to the war has resulted in one of the manufacturing companies abandoning the production of celluloid and turning to the manufacture of nitrocellulose for military purposes; owing to the cessation of imports of celluloid from Germany, the recent supply has scarcely been adequate. A large expansion has also resulted in the paper making industry, consequent on the cutting off of imports; production during 1915 is stated to have amounted to 210,000 tons. Filter paper is now being manufactured in Japan. The difficulties experienced in obtaining an adequate supply of sulphite pulp are being overcome, and shortly Japan will be independent of raw materials for paper.

Prior to the war, phosphorus was imported into Japan to the extent of 70,000 lb. annually; only two Japanese factories produced it, and their output was only about 12,000 lb. The rise in prices following the outbreak of war caused a greatly increased production, which is now about 37,000 lb. annually, and is being enlarged rapidly. Potassium chlorate is another substance of which the greater part (3000 tons out of 4000 required) was formerly imported; several firms have taken up this manufacture since the outbreak of war and the former producers have increased their output, with the result that an over-production is feared in the future.

INDUSTRIAL AND SCIENTIFIC RESEARCH IN CANADA.

A statement has been issued by the Honorary Advisory Council on Industrial and Scientific Research which was appointed by the Dominion Government in December, 1916, to the effect that some forty projects, each bearing on vital phases of scientific conservation and development of Canada's natural resources, have been submitted to the Council. Each one is being carefully considered, with a view to applying the scientific and well-considered principles of technical research to the solution of the industrial problems of Canada, both for the present and for the future.

Some of the larger projects now in view include a comprehensive industrial census; the training and utilisation in industrial establishments of "efficiency experts"; the creation of technical laboratories at the great industrial centres to give free help to manufacturers in solving their problems; the utilisation and development of fuel resources, particularly those of the Prairie Provinces; and the preservation of the diminishing timber resources of Eastern Canada.

Industrial Census.—The Council will issue questionnaires to Canadian manufacturers, technical societies, Government Departments, and universities, asking for information with reference

to the laboratories and various other agencies of research now in operation in the Dominion; the men now engaged in or available for research work; the raw materials required for Canadian industries; the by-products produced but not at present utilised; and other information required in the development of the Council's work.

Establishment of Fellowships.—In order to provide a body of men who have been thoroughly trained in science and its application to industry, the Council will recommend the establishment of twenty or more studentships and fellowships in Canadian universities and technical schools. Arrangements will also be made by which, after graduating, men will be placed in one or other of the great manufacturing establishments, and they will thus be fitted to aid in the development of the industries of the Dominion.

Industrial Research Bureaux.—In order to furnish direct assistance to the manufacturing industries of Canada at once, the Council are recommending the establishment at certain of the great industrial centres of the Dominion, such as Toronto, Montreal, and Winnipeg, in co-operation with the Provincial Governments or other bodies, of industrial research bureaux, where a complete set of technical magazines and trade journals will be available, and where technical staffs, provided with suitable and properly equipped laboratories, will assist manufacturers in solving problems which present themselves in factories or works.

In addition to these broad general movements for the advancement of the industries of the Dominion, the Council have decided to examine carefully a number of specific projects which have been submitted to them, and which appear to give promise of yielding valuable results. They have also decided to recommend that work should be at once started with a view to the provision of an adequate supply of good fuel for the western plains, more especially in the Provinces of Saskatchewan and Manitoba. There are in the former Province large supplies of lignite, of comparatively little value for domestic or manufacturing purposes. The Council, however, believe that by a special treatment there may be produced from this lignite two grades of briquetted fuel, one similar in character to anthracite or hard coal, and the other resembling soft coal in general character; and that at the same time very valuable by-products may be secured.

WORKS ORGANISATION AND EFFICIENCY.

BY PROFESSOR W. RIPPER, D.ENG., D.SC.

Royal Society of Arts, May 9th, 1917.

In order to maintain a higher rate of wages than prevailed before the war, and to do so without injuring the employer and without the necessity of industrial strife between employer and employed, the only method is to increase the national output of wealth-producing goods and services, so that there may be more wealth to distribute than was the case before the war. To bring this about the following things at least will be necessary:—1. The continuance after the war of improved relations between employers and their workmen. 2. The introduction of improved organisation and methods in our factories and work-shops.

Already great changes in this direction have taken place. There has been an enormous improvement in our methods of working, as well as in the spirit of willingness to work together and to co-operate and associate, the effect of which has been to secure a rate of output exceeding anything ever before obtained. There is, however, the danger that after the war this spirit of co-operation will not continue, and that the subjects of dispute between Capital and Labour

will be so numerous as to make serious disputes more or less inevitable. In the past our commerce, trade, and manufacture have been conducted too much for the one object of profit only and without any regard whatever to human and neighbourly considerations.

It is encouraging to note the increasing recognition of the value of mutual discussion between the representatives of masters and men, not merely for the purpose of settling disputes, but for purposes of mutual helpfulness to clear up a difficult situation. It is better understood now than ever before that the interests of an employer and his workpeople have more in common than was formerly supposed.

Increased output after the war does not mean that our workers are to be called upon to work harder physically than they did before the war, but that there will be a demand for more brains, that inefficient methods and appliances must give place to better and more efficient methods, and, above all, that we must begin to organise our industries on a scale commensurate with the task which lies before us.

It is owing to the fact that businesses in this country are conducted on so small a scale that our costs per unit of output are so excessive, and that our manufacturers are handicapped by not being able to compete in price against larger organisations abroad. The methods of the small employer are not properly manufacturing methods, they are the methods of the manual worker, and as such, in some special industries where skilled craftsmanship is indispensable, they will still remain as a permanent factor of high-grade industry; but for trades in general that can be more profitably carried on on a large scale by means of repetition machine work, they will of necessity be superseded by the component specialist whose output is large and whose standing charges are relatively small. It is by means of manufacture by quantity and by special machinery that costs are reduced and business increased. To carry on business in any industry along the line above indicated there is need of a very much more whole-hearted attempt at association under some central or agreed control than has hitherto taken place.

Fortunately, great changes are taking place at the present moment in this direction. Firms in all sorts of industries all over the country are combining together for the purchase of their raw material, the sub-division of the processes involved in their particular department of trade, and the selling of their products in the home and foreign markets through a single organisation instead of by a multiplicity of small isolated and costly efforts of their own. They prefer to unite their efforts so as to be able to compete successfully with their foreign rivals rather than spend their substance in fighting each other at home.

The leading principle which must dominate modern manufacturing methods throughout is the elimination of waste—waste of time, waste of material, waste of effort, waste of health. To increase the scale of wages paid, drastic steps must be taken to reduce waste in all directions, and if a really earnest endeavour is made by both employers and workmen, each in their own way, in this direction, it will be quite possible to increase so greatly the wealth-producing power of all the trades in this country as to secure after the war an increased output of work sufficient to produce the increased rate of wages desired.

The prevention of waste is essentially a scientific problem, and it must be attacked by the scientific method. As a result of careful study of power plants with a view to discovering and removing sources of loss, the cost of the unit of power to-day is anything from one quarter to one-tenth of what it was fifty years ago.

The importance of a good system of costing as a means of efficient control of a business, and of discovering weak places in it, is more and more fully realised by manufacturers; such a system is in fact in these days indispensable. It must present comparative results showing the progress separately of the various departments, in order to discover the relative merits of their respective methods, and to discover also the effects of changes of methods. A good costing system intelligently handled points out the direction in which improvement is possible and necessary, and is a splendid instrument of efficiency.

Above all, there is a great demand for skilled and competent leadership and for organising and administrative ability. The demand of every branch of industry for men of scientific training and experience will be greater in the immediate future than ever before.

Finally the provision of trade training for apprentices, and of a continued education through part time for all boys up to the age of seventeen or eighteen, is now admitted to be a necessity.

The future of our industry must be something more than a mere fevered scramble for profit on the part of the employers or for wages on the part of the men. Trade and industry must be recognised as the natural healthful and normal means whereby the nation is able to express itself in useful service, and to realise itself in ever-improving quality of work, as distinguished from the increase of mere quantity.

Obituary.

LORD ALLERTON.

The Right Hon. Lord Allerton, F.R.S., died in London on April 4th, aged 77 years.

Born at Otley, Yorks., in 1810, William Lawies Jackson commenced at an early age to

learn his father's business—that of a leather merchant and tanner—and when his father died in 1857 he took entire control of the business, working it up with the greatest energy and spirit to the position which it occupied when, for private reasons, it was given up in 1912. During that period the firm of W. L. Jackson, Ltd., had become one of the best known in the leather trade, having a very large output. He was one of the originators of the Leeds Leather Fair and also for some years President of the Leeds Leather Trades Association, in addition to being a member of the Leather Industries Committee of Leeds University. He took a very keen interest in the latter institution, being a life governor and member of the Council, both before and after it had received university rank.

Jackson commenced his connection with public affairs at an early age; he was a member of the Leeds Council from 1869 to 1880, and was elected Mayor of Leeds in 1895. He sat in Parliament almost continuously from 1880 to 1902, being appointed Financial Secretary to the Treasury in 1886—an office which he held for about six years—and Chief Secretary for Ireland in 1891; he only retained the latter office for a few months, until the Government went out of office. He sat on a very large number of Royal Commissions and Government Committees, including the Royal Commission on Trade, the Census of Production Act Committee, and the Royal Commission appointed in 1891 to inquire into the coal supplies of the United Kingdom, of which he was Chairman.

He had been a member of this Society since 1893, and, on the occasion of the Annual Meeting at Leeds, in 1895, he conducted a party of the members through his works.

He was made a member of the Privy Council in 1890, and in 1902 was raised to the peerage, assuming the title of Baron Allerton of Chapel-Allerton.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56 Rue Ferou 8, Paris (3e.). Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Loose material; Method of and means for the transference of—C. E. Blyth, Rugby, and L. Lister-Kaye, Southam. Eng. Pat. 104,775. Apr. 8 and Aug. 26, 1916. (Appl. Nos. 5188 and 12,086 of 1916.)

THE loose material is fed between two surfaces in yielding contact and moving in the same direction at a high velocity. In this way a momentum is given to the loose material, which is projected forward for a distance which varies with the velocity of the moving surfaces.—W. H. C.

Filter press. F. F. Briginshaw, London. Eng. Pat. 104,936. Mar. 29, 1916. (Appl. No. 4636 of 1916.)

A FILTER press is composed of a series of superposed horizontal filtering discs each mounted in its own frame. The frame comprises a ring, *a*, provided at its lower part with radial perforated

spokes, *d*, connected to a hollow central boss which is divided by a vertical partition into two compartments, *e* and *f*. A disc of wire gauze

or a spirally wound wire is laid on the spokes and supports the filtering disc, *b*. Handles, *3*, are attached to the ring, *a*, to facilitate handling

the sections, a number of which are built up in a frame and maintained in position by a screwed press-head, *c*. The central bosses are perforated as at *j*, *k*, the perforations communicating with the spaces, *e* and *f*, in alternate discs. The liquid to be filtered is introduced by the pipe, *l*, and perforations, *e'*, into the column, *i*, so that it passes through the openings, *j*, and fills the alternate flat spaces between the discs. The liquid filters through the discs into the remaining alternate spaces, and thence through the openings, *k*, and conduit, *f*, to the outlet. In a modification, the spokes, *d*, are made of an inert metal attached to a light ring which is enclosed and supported by an outer ring of malleable iron or steel.—W. F. F.

Filler pulp cakes or discs for filler presses; Apparatus for compressing—F. F. Briginshaw, London. Eng. Pat. 105,323, Mar. 29, 1916. (Appl. No. 3551 of 1917.)

THE filter pulp cakes for use in the apparatus described in Eng. Pat. 104,936 (see preceding abstract) are made in the press illustrated. The pulp is placed in the space, *b*, above the perforated plate which is supported on the pressing table, 5. Pressure water is supplied through the pipe, 10,

and openings, 11, to the cylinder, 7, so that the annular ram, 6, and the smaller ram, 16, are raised together to compress the pulp against the cover, 12, which is locked by the catch, 13. After a predetermined compression, the main ram is stopped by the shoulder, 8, the cover, 12, is swung out of position, and pressure water passing through the openings, 17, forces up the smaller ram, 16, to raise the compressed cake so that the frame described in the prior patent may be placed upon it. The apparatus may be worked by a three-way valve in the pipe, 10, and the compressed air in the top of the column, 9, expedites the discharge of water. Alternatively, the smaller ram, 16, may be operated mechanically.—W. F. F.

Drying or roasting apparatus of the rotary chamber type. O. Elsworth, Newcastle-on-Tyne, Eng. Pat. 104,939, Mar. 30, 1916. (Appl. No. 4725 of 1916.)

A HORIZONTAL, cylindrical drying chamber, *a*, is provided with toothed rings, *c*, which are rotated with the cylinder by driving pinions, *d*. The material is fed into the cylinder at the left-hand end and is carried round by the channel-shaped carriers, *h*. Horizontal bars, *n*, pass through the cylinder and are supported independently of it, and bent plates, *j*, are pivoted to the bars at *m*. The material falls on to the plates and is progressively carried forward, and discharged at the

other end. The lower ends of the plates are pivoted to the bar, *p*, which may be moved longitudinally by the screw, *q*, so as to alter the inclination of the plates to modify the rate of feed of the material. In a modification, the upper part of the plates may be fixed and the lower segments pivoted at the points, *i*, so as to be capable of angular adjustment.—W. F. F.

Dryer. L. R. Jackson, Assignor to J. S. Schofield's Sons Co., Macon, Ga. U.S. Pat. 1,220,130, Mar. 20, 1917. Date of appl., Mar. 30, 1916.

THE shell of a cylindrical dryer is provided with openings covered by interior liner plates, the edges of which are overlapped by "flights" bolted to the shell. The openings of the cylinder allow material to drop through when any of the liner plates wear out.—W. H. C.

Drying apparatus for peat and the like. C. D. Jenkins, Assignor to Peat Coal, Ltd., Boston, Mass. U.S. Pat. 1,220,131, Mar. 20, 1917. Date of appl., May 1, 1915.

A NUMBER of air-jacketed cylinders are placed one above the other. The material to be dried is fed into the uppermost cylinder and passes down to the lowest, from which it is discharged, being moved forward by horizontal rakes which extend into each cylinder from a central vertical shaft. The teeth of the rakes work between teeth which extend upward from the floors of the chambers. Heated air is passed through the jackets, and means are provided for drawing off the vapour.—W. H. C.

Drying apparatus. C. H. Benedict, Chicago, Ill. U.S. Pat. 1,221,129, Apr. 3, 1917. Date of appl., Apr. 17, 1916.

A DRYING chamber having a heat-insulating covering is arranged in a pit having firebrick walls, and spaced from the walls. Waste gases from an adjoining furnace pass through the surrounding jacket to heat the chamber, and hot air is passed through the chamber from a hood over the furnace by a fan in the connecting conduit. An endless horizontal conveyor operates with its upper portion outside the chamber, so that articles may be placed thereon, and its lower portion within the chamber, moving in the opposite direction to the heated air.—W. F. F.

Dryer. R. Bernhard, Milwaukee, Wis., Assignor to Worthington Pump and Machinery Corporation. U.S. Pat. 1,221,412, Apr. 3, 1917. Date of appl., Sept. 5, 1914.

A HORIZONTAL, cylindrical, revolving casing is provided with transversely curved partitions extending for a part of its length and forming a flue and drying chambers. Each partition is composed of movable sections connected with the casing and having their ends approximately in line

with one another. Butt straps extend over the joints and are attached to one of the sections only, so as to permit relative movement.—W. F. F.

Drying kiln. P. W. Turner, Myndus, N. Mex. U.S. Pat. 1,221,776, Apr. 3, 1917. Date of appl., Sept. 20, 1915.

A DRYING kiln comprises a casing divided horizontally by heating pipes into a drying chamber above and a cold air chamber below. The air-supply flue for the lower chamber is provided with an automatic fan regulator, rotating in a transverse plane, and also with a baffle device. A larger discharge flue, in the top of the drying chamber, at the opposite end, is provided with a similar regulator and with a flared inlet.—W. F. F.

Stills and the like. British Dyes, Ltd., Huddersfield, A. T. Metcalf, Bradford, and W. Welch, Baildon, Yorks. Eng. Pat. 104,969, May 25, 1916. (Appl. No. 7409 of 1916.)

IN a still heated by horizontal steam pipes, a steam chest is fixed to the outside of one of the vertical walls, and divided into two parts by a vertical partition parallel to the wall of the still. Steam enters the outer compartment and passes into horizontal tubes fixed in the partition and extending through the wall of the still nearly to the opposite wall, the farther ends of the tubes being laterally perforated. The steam returns through concentric outer tubes which terminate in the wall of the still, so that the steam is discharged into the inner of the two compartments of the steam chest. The heating tubes thus resemble "field tubes," and are fixed at one end only, in plates which are slightly inclined, so that the tubes are also inclined and condensation water is discharged. Some of the inner tubes are shorter than others to equalise the heating, and the tubes are arranged in independent groups.—W. F. F.

*Chaff and other loosely aggregated materials; Apparatus for treating—*with steam, air, or other gases. W. R. Renshaw, Stoke-on-Trent, Eng. Pat. 105,096, Mar. 27, 1916. (Appl. No. 4525 of 1916.)

IN apparatus for treating or drying chaff or other loosely aggregated material with steam, hot air, or other gases, a steam ejector withdraws gas from the vessel containing the material, and forces it through a superheater, and thence, after addition of more steam, back to the vessel. A thermometer is provided on the inlet side of the superheater, and a thermometer, safety valve, and pressure and vacuum gauge on the other side of the superheater. Circulation is continued till the desired temperatures are reached. When treatment is finished the valves in the circulating system are closed and the heated air, gas, and steam withdrawn from the vessel by a water ejector connected to the pipe system between the vessel and the first valve.—W. F. F.

Annealing-furnaces. Regenerative furnace for annealing and like purposes. A. L. Stevens, Chicago, Ill. U.S. Pats. (A) 1,219,499 and (B) 1,219,500, Mar. 20, 1917. Date of appl., Sep. 10, 1912.

A REGENERATIVE annealing furnace has a series of combustion spaces formed by bridge walls spaced apart from the side walls of the heating chamber. In (A) a pair of regenerators is provided at one end, at about the level of the heating chamber, which is provided with a door at the opposite end. The regenerators are connected with two flues which pass below the heating chamber and are connected by other flues with each of the combustion spaces. In (B) separate regenerators are provided beneath and connected with each combustion space.—W. H. C.

Furnace. G. Rigg, Palmerton, Pa., and W. L. Coursen, New Rochelle, N.Y., Assignors to The New Jersey Zinc Co., New York, U.S. Pat. 1,220,789, Mar. 27, 1917. Date of appl., Apr. 19, 1916.

A FURNACE for roasting, calcining, and similar purposes is provided with a removable roof having a substantially flat bottom and a central feed opening. The roof is built up of a series of beams channelled for the reception of a cooling medium and provided at top and bottom with a series of inclines. The beams are spanned at the bottom by flat tiles resting on the inclines, and at the top by arched tiles, thus forming a series of combustion chambers. Means are provided for supplying a mixture of gas and air to the combustion chambers and for removing the products of combustion.—W. F. F.

Furnaces; Air-control system for [regenerative] —, W. H. Bradley, Pittsburgh, Pa. U.S. Pat. 1,222,519, Apr. 10, 1917. Date of appl., Feb. 29, 1916.

THE valve casings of a number of reversing regenerative furnaces are supplied with air by a blower which delivers it through a common main provided with a branch pipe for each valve casing. A control valve is provided in each branch pipe and is operated by a pressure-controlled device connected to the branch pipe between the valve and the furnace. An additional air inlet is provided in each valve casing, controlled by a valve operated manually.—W. F. F.

Refrigerating-machines. G. P. Carroll, Bridgeport, Conn. U.S. Pats. (A) 1,219,533 and (B) 1,219,534, Mar. 20, 1917. Date of appl., (A) Apr. 1, 1908, (B) Dec. 3, 1910. (B) Renewed Aug. 9, 1916.

THE claim is for a combination of a condenser, an evaporator, a coil in the chamber to be cooled, and a still to contain the absorbing liquid. The heating and cooling of the apparatus is automatically regulated (A) by thermostatic valves in the refrigerating chamber or (B) by means operated by the pressure of the refrigerant in the condenser.—W. H. C.

Condenser. G. P. Carroll, Bridgeport, Conn. U.S. Pat. 1,219,535, Mar. 20, 1917. Date of appl., Nov. 4, 1913.

A CONDENSER consists of a horizontal tank provided with an inlet and with an outlet at the bottom. A gas conduit enters the tank through the inlet, descends within the tank, and discharges near the bottom. A water conduit enters the tank near the bottom and leaves it at a higher place: it is formed of sections disposed horizontally within the tank and connected in series by other sections outside the tank. A water pipe leads from the outlet end of the water conduit, enters the gas conduit, traverses part of it longitudinally outside the tank, and then emerges from it.

Evaporator. R. J. Coach, Assignor to The Sub-Surface Vacuum Development Co., Cleveland, Ohio. U.S. Pat. 1,220,191, Mar. 27, 1917. Date of appl., Apr. 1, 1912.

THE liquid to be evaporated is contained in a shallow closed pan communicating through an aperture in the upper part of a partition with an adjacent air chamber to which suction is applied. The liquid is heated and agitated by steam pipes which can be moved vertically into and out of the liquid by a cranked shaft extending horizontally above the pan and connected by vertical rods to the steam pipes.—W. F. F.

Evaporating process and apparatus. F. G. Wheeler, Assignor to Bleach Process Co., Appleton, Wis. U.S. Pat. 1,222,340, Apr. 10, 1917. Date of appl., June 17, 1916.

A SOLUTE is removed from a solution, or from a

mixture of two solutions, by evaporating the solvent and crystallising the solute, and then circulating the solution so that at one point it flows upward into a vessel with a conical bottom. The reduction in velocity at the enlarged cross-section of the stream causes the crystals of solute to remain suspended at that point. The clear liquid above is withdrawn by a pipe at the top and treated again as often as desired. The process is applicable to the removal of sodium chloride from a solution containing also sodium hydroxide.

—W. F. F.

Chemical [mixing] apparatus. Z. Ostenberg, San Francisco, Cal., Assignor to International Cellulose Co., Reno, Nev., U.S. Pat. 1,220,778, Mar. 27, 1917. Date of appl., Feb. 7, 1916.

POWDERED material is discharged from a hopper by a screw conveyor into the top of a tall, vertical cylinder through which it is caused to fall in an annular stream by means of a conical spreader at the top. Liquid is sprayed from a central sprayer into the falling material, and the treated material is cooled in the lower half of the cylinder by an external cooling coil, and finally discharged by a screw conveyor. Means are also provided for simultaneously adding material to, and abstracting material from the mass in the cylinder.

—W. F. F.

Dehydrating apparatus [for air]. G. H. Benjamin, New York, U.S. Pat. 1,220,815, Mar. 27, 1917. Date of appl., Aug. 1, 1914.

AIR is drawn through a chamber in which brine is circulated, from an inlet at the bottom to an outlet at the top which is connected to a long horizontal casing provided with heating pipes connected at one end to a heater and at the other end to a chimney stack. The other end of the casing is connected to the suction side of the air circulating pump. The delivery side of the pump is connected to a second casing communicating along its length with a series of cells through which the air passes to another casing over the top of the cells and communicating with each of them, and thence to the chimney stack.—W. F. F.

Gas or mixture of gases: Method of separating certain constituents from a— L. Bradley, East Orange, N.J., and W. A. Schmidt, Los Angeles, Cal., Assignors to Research Corporation, New York, U.S. Pat. 1,221,505, Apr. 3, 1917. Date of appl., July 23, 1914.

A CONSTITUENT is separated from a gas or mixture of gases by injecting into it dust or other finely divided solid particles capable of reacting chemically or physically with the constituent and absorbing it. A cloud or mist is formed and is precipitated by subjecting the gas to the action of an electric field.—W. F. F.

Compressed-air washer. B. C. Donham, Glen Ridge, N.J., Assignor to Spray Engineering Co., Boston, Mass., U.S. Pat. 1,222,511, Apr. 10, 1917. Date of appl., Dec. 6, 1915.

COMPRESSED air is passed through a horizontal conduit, into which liquid is sprayed over the whole cross-section in different conditions of fineness, in the direction of movement of the air, so that the most finely-divided liquid is retained as moisture for the precipitation of foreign particles. Two separate sets of sprayers, one being provided with atomising screens, are used, with a liquid-removing device between them. The finely divided liquid is discharged from the last set of sprayers in diagonal paths toward the centre of the air stream.—W. F. F.

Electrostatic separator for inflammable materials. J. Kraus, Brunswick, Germany, U.S. Pat. 1,222,505, Apr. 10, 1917. Date of appl., Oct. 27, 1914. SEE Eng. Pat. 26,802 of 1913; this J., 1914, 681.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Gasification of—without residue [except of ash]. A. Naumann, Chem.-Zeit., 1917, 41, 6—8.

THE method of converting coal directly into heating gas, by-products, and ash, as covered by the patents of the Dellwik-Fleischer Wassergases, and E. Dolensky (this J., 1911, 585; 1915, 268; and 1917, 380), is described and its compulsory adoption (in Germany) under State control suggested. It is urged that district stations be installed and conducted in the public interest, and that private consumption of solid fuel be prohibited. The gas, which has been named "tri-gas," is a mixture of water-gas and illuminating gas with, in special cases, a small proportion of producer gas, and results with an experimental installation show that it has a high calorific value. The process may be regulated by adjusting temperature and steam supply so that the best results, as regards yield of gas, tar, or ammonia, are obtained with any kind of fuel, and is claimed to be highly economical.

—F. SOBX.

Coke gasification; Economy of— J. E. Enright, Gas J., 1917, 138, 185—186.

RESULTS obtained from the carburetted hydrogen plant at Tralee, Ireland, over a period of ten months, are as follows. Carburetted hydrogen gas made, 15,225,100 cub. ft.; coke used, including boiler fuel and stand-by plant, 363 tons, 9 cwt.; tar used in plant, 10,197 gallons; wages, £128 12s. 6d., working out at an average cost of 9d. per 1000 cub. ft. into the holder. During the same period 1357 tons of coal, at an average cost per ton of 55s., was carbonised, giving, 14,885,900 cub. ft. of gas. Thus 363 tons of coke yielded more gas than 1357 tons of coal. The working of the plant has been most satisfactory, important economies having been effected in renewal, repair, and maintenance of retorts, number of stokers required, and other incidental expenses. The plant can be operated by one man. With regard to the distribution and consumption of the mixed gas, a burner adjustment for a 50% gas has been found suitable for any mixture between this and carburetted hydrogen gas alone. Carbon monoxide can be kept well below 18% and the mixed gas varies between 475 and 500 B.Th.U., but a variation between 400 and 500 B.Th.U. causes no trouble after adjusting the burners or stoves for the mixed gas. In gas engine trials it was found that the B.H.P. was not affected by the variation of the B.Th.U., the consumption of gas being in inverse proportion to the latter. The consumption of gas in fires and stoves works out similarly, whilst with the incandescence mantle the 400 B.Th.U. gas has been found as economical and efficient as the richer gas.—J. E. C.

Wood in gas making. Gas J., 1917, 138, 191

RESULTS of experiments at Romorantin Gas Works in the distillation of fir and oak for gas making are as follows. The wood was distilled, unmixed with coal, in retorts, 10 ft. x 25 ins. x 14 ins., in quantity to yield from 10 to 20% of the make of gas from coal. Each charge was about 100 kilos. of fir or 120 kilos. of oak, yielding about 25 cb. m. (900 cub. ft.) of gas. Costs are given as:—Fir, 40 frs. per ton; labour, 4 frs.; furnace coke, 17.5 frs.; total, 61.5 frs. Net cost (deducting 50 frs.

from sale of 10 hectolitres of charcoal), 11.5 frs. Oak. 58.5 frs. per ton; labour, 4 frs.; coke, 17.5 frs.; net cost, 10 frs. The charcoal sells readily, the weight per hectolitre being 15 kilos. in the case of fir and 18 kilos. in that of oak.—J. E. C.

Gas washing [for benzol and toluol]: analysis of products; control of stills. A. Edwards. Yorkshire Junior Gas Assoc., Apr., 1917. Gas J., 1917, 138, 187—191. (See this J., 1916, 587.)

In gas washing by oil it is necessary to determine the quantity of oil required per ton of coal. There is a dividing line in regard to the amount of oil used below which economy in steam is more than balanced by loss of benzol, and above which increasing recovery of benzol is more than balanced by increasing steam and water cooling demands, and this point must be determined for the particular plant and conditions. Some conditions affecting this point are:—(a) Quantity of benzol in the gas. (b) Type of washer. (c) Temperature of oil. (d) Cost and pressure of steam. (e) Cost of water. In coking installations 100 galls. of wash oil per ton of coal is commonly regarded as representing the best point, but it is not certain that the conditions in coking installations are the best or comparable with average gas-works conditions. In coking installations the tower scrubber is used in most cases, whilst gas works have adopted mechanical washers of the rotary or centrifugal type. As against the extra cost of the tower scrubber with its filling may be set the running costs, maintenance, and power costs of the mechanical scrubbers. There are three ways of considering the efficiency of a gas-washing plant. First there is the volumetric efficiency, the proportion of benzol recovered to the total quantity present. Secondly, the "constitutional" efficiency, due to the method of applying the washing liquid, and a constant for the particular method employed. Thirdly, the "mechanical" efficiency, represented by the comparison of the theoretical minimum volume of oil to ensure equilibrium between gas and oil with the actual volume found necessary. For maximum efficiency the flows of gas and oil should take place on the counter-current principle through a series of saturations increasing by very small stages. In tower scrubbers this is only obtained if the washing medium travels evenly and progressively over the surface of the packing material. In rotary washers the action is divided into definite steps according to the number of sections. The proportion of benzene in the wash-oil in equilibrium with benzene vapour in the gas can be determined for any particular temperature, and from the data thus obtained the theoretical amount of wash-oil required for absorption can be calculated. If the wash oil is passed through a single chamber, equilibrium is attained when 50% of the vapour is absorbed, and with washing systems of two, four, and eight chambers the volumetric efficiencies will be 75, 87, and 93% respectively. Town gas of 500 B.Th.U. net calorific value, from horizontal and inclined retorts, contains usually 0.8% by volume of benzene vapour, corresponding to a partial pressure of 6.1 mm. of mercury, and requiring under summer temperatures a circulation of 48.8 to 56 gallons of wash oil per ton of coal. The benzene concentration in the wash-oil in equilibrium with 0.8% benzene vapour in the gas varies from 9.8% at 5° C. to 3.05% at 30° C. Experience with an eight-chamber washer points to the use of 1.1 to 1.5 times the theoretical quantity of wash oil, the practical circulation for 0.8% benzene in the gas at a temperature of 25° C. being 53 to 73 gallons per 10,000 cub. ft. The cost of steam is usually about half the total cost of recovery. Efficient practical working may be maintained by: (1) Measuring the wash oil used, preferably

by a V-notch weir; (2) indicating the amount of hydrocarbon vapours extracted, e.g., by means of a couple of jet photometers with scales constructed by direct experiment; (3) indicating the volume of steam used in the still; (4) periodical tests of the crude benzol; (5) examination of wash oil before and after the still; (6) determination of viscosity of wash oil. Where crude benzol is made and sold on the usual basis of 65%, a complete analysis is not necessary, unless the proportion of paraffin is objected to, but where the crude material is rectified, analysis plays an important part. The author gives a scheme for the analysis of crude benzol based on the methods of Spielmann, Colman, and on his own boiling-point method (this J., 1915, 168; 1916, 396, 587). The following is an average of 5 analyses of crude benzol: benzene, 54.07; toluene, 15.00; solvent naphtha (up to 160° C.), 4.98; creosote, 16.65; unsaturated hydrocarbons, 8.16; carbon bisulphide, 0.30; paraffins (up to 139° C.), 0.80%. These figures are for the ultimate proportions present and do not give any indication of the distribution of the paraffins. The latter are important to-day since their presence in benzene and toluene intended for the manufacture of explosives is objectionable. The full scheme of operations for the analysis of a crude benzol is somewhat involved, and the author gives a simpler method of following the working of a primary still at the different stages. In testing the wash oil before and after the still, 4000 c.c. is distilled to 240° C. in a metal still provided with a jacket. Water is separated and recorded, and the distillate redistilled to 160° C. through a column. This represents the total benzol, toluol, and solvent naphtha. In working up to fairly pure products it is advisable to make free use of the dephlegmator, returning down the column up to four times as much as is permitted to pass into the condenser.—J. E. C.

Concrete; Destruction of — by gas liquor. E. Ott. Chem.-Zeit., 1917, 41, 161.

A GAS LIQUOR tank of armoured concrete showed signs of leaking. The liquid which escaped contained ammonia, free and fixed, much calcium, and as acid radicle thiosulphuric and thiocyanic acids but no hydrogen, sulphide or sulphuric or hydrochloric acids. The ammonium salts in the liquor had attacked the free lime in the concrete, forming soluble calcium salts. Coating the inside of the tank with materials such as tar is only partly effective, as it is difficult to avoid the development of cracks. A suitable lining to the tank is to be preferred—lead, iron, or glass being suggested. Zinc is not a suitable material. Where iron is used, it is recommended to keep the atmosphere of the tank free from air and so avoid rusting. For this purpose coal gas is recommended.—H. J. H.

Lignite gas oils; Oxidation of — and of similar substances by ozone. C. Harries, R. Koetschau, and E. Fonrobert. Chem.-Zeit., 1917, 41, 117—119.

THE object of the experiments was the production of fatty acids from the unsaturated portion of the heavier gas oils from the distillation of Halle lignite (Webau). The oil boiled at 125°—220° C. under 10 mm. pressure. It was light brown, viscid, with disagreeable smell, and had a flash point of 125° C. The iodine value was 50—60. Similar results were found on ozonising shale oils. Ozonised oxygen was passed through a train of vessels containing the oil until the latter had increased in weight by 10%. Formic acid and formaldehyde were carried forward and condensed. The oil now contained an ozonide which was decomposed by steam. An excess of potash was added and steam again blown through. A potash soap was thus produced. This was purified by extraction with benzene and again ozonised, when

its colour improved. By a further treatment with steam any ozonide formed was decomposed and the soap was then concentrated by vacuum evaporation. The soap is stated to have given good results in the leather industry. By an adequate ozonisation all the unsaturated compounds were removed from the oil, and a paraffinoid residue of high quality remained. The chemistry of the process has not been thoroughly worked out, but the unsaturated compounds of the oil are believed to have conjugated double bonds, perhaps at the end of a chain. Trials on a works scale gave results similar to those in the laboratory.—H. J. H.

Montan wax and its behaviour on distillation. J. Marcusson and H. Smelkus. *Chem.-Zeit.*, 1917, 41, 129—136, 150—151.

THERE are three kinds of montan wax in commerce, viz., crude wax or bitumen, distilled wax, and refined wax. Crude montan wax is obtained by the extraction of dried lignite with benzene—a good sample of lignite containing 10—20% of available bitumen. Fischer and Glud (this J., 1916, 1901) have shown that the yield can be increased from 11% to 25% by working at 260° C. and 6 atm. pressure, but the residue cannot be briquetted as is normally possible. The crude waxes differ widely according to the source, Thuringian lignites yielding a brittle wax (m. pt. 80°—90° C.), while Bohemian lignites give a viscid liquid. Montan wax resembles beeswax in its resistance to saponification, and like the latter, is free from glycerides, consisting essentially of esters of monohydric alcohols and free acids of high molecular weight. The difficulty of saponification leads to some uncertainty as to the chemical nature of the unsaponifiable portion and this is discussed in detail. Solvents, e.g., alcohol and benzene, extract from the crude wax a resinous portion, the properties of which are described. A better separation of the resin from the wax can be effected by the use of liquid sulphur dioxide as employed by Fischer and Glud. On the other hand the extraction with benzene under pressure, already referred to, leads to an increased contamination of the true wax with resin. Many attempts at a chemical purification of crude wax have been made to obtain without distillation a product suitable for candle manufacture, but without success. The origin of montan wax is a subject of discussion. The authors hold that both vegetable waxes and resins have been involved, the proportions depending on the nature of the parent plants. Distillation of crude wax under atmospheric pressure leads to considerable decomposition. This is considerably reduced by working under diminished pressure and especially with superheated steam at 250° C. After further purification of the product by treatment with benzene, pressing, and decolorisation, a white crystalline product (m. pt. 70°—80° C.) results, containing mainly montanic acid, $C_{29}H_{58}O_2$. The yield in this process is stated as being only 30%. An examination of the distillation product led to the following conclusions as to the causes of loss of yield:—1. Decomposition of resinous and sulphur compounds during distillation. 2. Splitting of the wax esters into free fatty acids and unsaturated hydrocarbons. 3. Formation of ketones by union of two molecules of fatty acid and splitting off of water and carbon dioxide. 4. Formation of a pitchy residue. While crude wax is strongly optically active, distilled and refined montan wax is inactive. The activity is due to the resinous part of the crude material. (See also this J., 1909, 878, 991; 1916, 917.)—H. J. H.

Determination of free alkali in petroleum soaps. Charitschkov. See XII.

PATENTS.

Briquetting machine. J. F. Lovejoy, New Rochelle, N.Y., Assignor to A. Stein, New York. U.S. Pat. 1,221,878, Apr. 10, 1917. Date of appl., Apr. 9, 1913.

A MACHINE for briquetting powdered coal consists of a pair of rotary drums revolving in opposite directions. The drums are provided with radial pockets, fitted with plungers. As the point of tangency approaches, suitably arranged cam tracks bring about a compressing movement of the plungers. Means are provided for feeding the powdered fuel into the pockets of one of these barrels, partially compressing the fuel to carry it to the tangential region, and afterwards ejecting the fully compressed briquette.—J. E. C.

Binder [for briquettes, from sulphite-pulp waste lyes]. L. H. Woddrop, Arcola, N.J., Assignor to Robeson Process Co., New York. U.S. Pat. 1,221,259, Apr. 3, 1917. Date of appl., Dec. 4, 1916.

THE composition consists of an intimate mixture of bituminous coal, dried sulphite waste liquor, bituminous matter, such as pitch, and an inert granular material, such as sand.—J. F. B.

Gas producers. G. H. Isley, Assignor to Morgan Construction Co., Worcester, Mass. U.S. Pat. 1,221,055, Apr. 3, 1917. Date of appl., June 30, 1913.

A GAS producer comprises a fuel section and a fuel-feeding mechanism, with means for causing relative rotation between the two. The feeding mechanism is disposed eccentrically to the fuel section and consists of a hopper and a shelf, the hopper feeding the shelf and a rotary member forcing the fuel over the edges of the latter.—J. E. C.

Hydrogen or a mixture of hydrogen and carbon monoxide; Manufacture of—. C. B. Tully, Westminster. Eng. Pat. 16,932 of 1915; date of appl., July 3, 1916.

IN the lower part of a cylindrical apparatus is a combustion chamber in which a reducing gas is made by blowing air, or air and steam, into incandescent fuel. This chamber extends upwards into a fuel supply chamber, which is surrounded at its lower part by a reaction chamber containing iron ore in direct communication with the combustion chamber by means of holes and passages. Surrounding the upper part of the fuel supply chamber is a steam superheating chamber through which the oxidised gases pass, and which is provided with a valve-controlled outlet. After the iron ore has been reduced, the supply of reducing gas is cut off, the outlet pipe is closed, and steam is admitted through a pipe at the top of the apparatus; this passes through the superheater and over the iron, the hydrogen being either tapped through a pipe just below the reaction chamber or passed through the incandescent fuel and led away through a pipe at the bottom of it. Steam or liquid hydrocarbon may be injected directly into the combustion chamber at a point situated between it and the reaction chamber. Air may be admitted at the bottom of the superheater to burn the carbon monoxide, and the heat of combustion utilised to maintain the temperature.—E. H. T.

Combustible liquids; Treatment of—. C. White and C. F. Killar, London. Eng. Pat. 105,256, Apr. 1, 1916. (Appl. No. 4824 of 1916.)

AN inflammable substance for use as fuel for internal combustion engines is made by dissolving a gaseous hydrocarbon (preferably acetylene) and petrol in a mineral oil hydrocarbon fraction, the latter being preferably a petroleum fraction having sp. gr. 0.775 to 0.780, b.pt. about 150° to 230° C., and flash point 79° F. (26° C.). Liquids

such as ether, alcohol, or acetone may be added to retain the gaseous hydrocarbon in solution.
—J. E. C.

Mineral oils; Treating — to increase the yield of light-gravity oils. D. T. Day, Washington, D.C. U.S. Pat. 1,221,698, Apr. 3, 1917. Date of appl., May 3, 1913. Renewed Feb. 23, 1917.

HEAVY oils, such as gas oil or other distillates having a higher boiling point than gasoline, are subjected to distillation at a cracking temperature and at a pressure greater than the atmospheric pressure. Sulphur or sulphur compounds are added at intervals to facilitate the cracking of the heavier oils. Hydrogen-carrying gas or vapour may also be added and the mixed vapours passed through porous contact substances or a catalytic agent.—J. E. C.

Petroleum; Obtaining products from — by decomposition of component hydrocarbons. H. P. Chamberlain, Buffalo, N.Y., Assignor to Standard Oil Co. of New York. U.S. Pat. 1,221,790, Apr. 3, 1917. Date of appl., Oct. 20, 1913.

CRUDE petroleum is distilled until the distillate contains more than 10% by vol. of hydrocarbons having a viscosity ranging between 70 and 170 seconds at 100° F. (38° C.), and from this point the distillate is collected separately up to the point at which it is no longer free from still wax or other matters of sticky character. The collected product (heavy paraffin) is then distilled at decomposing temperatures under a pressure of not less than 30 lb. per sq.in.—J. E. C.

Hydrocarbons; Method and apparatus for fractionating —. L. E. Hirt, Charleston, W. Va. U.S. Pat. 1,222,402, Apr. 10, 1917. Date of appl., July 21, 1915.

OIL, mixed with steam, is subjected to the action of an electric arc in a closed chamber. Steam is decomposed and the liberated hydrogen reacts with the oil forming a compound therewith. The pressure in the chamber is controlled during the operation, and the oil vapours produced are withdrawn and condensed.—J. E. C.

Reactive products from paraffin hydrocarbons; Preparation of —. H. Zerning, Berlin-Halensee. Ger. Pat. 295,594, May 5, 1915.

PARAFFIN hydrocarbons and water are sprayed into a system of tubes, of which the first section is heated to about 300° C., the next to about 500° C., and the last to about 700° C., the most favourable excess pressure being 0.2 atmos. Highly reactive products are obtained, which can be readily oxidised, nitrated, sulphonated, etc. For example, the product from high-boiling American petroleum yields with sulphuric acid bodies resembling shellac, with nitric acid and potassium permanganate oils with a pleasant odour, and by simple nitration products which can be used in the manufacture of explosives.—F. Sr.

Expressing liquid from materials; Apparatus for —. Process for expressing liquid from peat. J. W. Hinchley, London. U.S. Pats. 1,222,209 and 1,222,210, Apr. 10, 1917. Date of appl., Sept. 25, 1916.

SEE Eng. Pats. 101,782 and 3998 of 1915; this J., 1916, 1254.

Drying apparatus for peat and the like. U.S. Pat. 1,220,131. See I.

Method of and apparatus for producing sulphate of ammonia. Eng. Pat. 104,155. See VII.

Manufacture of a non-volatile unsaturated hydrocarbon from petroleum. U.S. Pat. 1,220,821. See XIII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

[Tungsten] crystals (crystalline wire for incandescence lamps); Manufacture of filiform —, by the method of J. Pintsch A.-G. W. Böttger, Deutsche Bunsen-Ges., Dec., 1916. Chem.-Zeit., 1917, 41, 10.

FILAMENTS prepared from a mixture of tungsten and thorium oxide by extrusion are found from an examination of etched specimens to consist of numerous crystals which are flexible in themselves but allow of great brittleness in the filament at points of mutual juncture. Relatively long crystals are obtained by very intimately incorporating the oxide with the metal, and suitable crystallisation is induced in filaments made with the aid of a binding agent, by extrusion, by causing these to travel through a zone heated to 2400°—2600° C., at a rate which is less than the rate of crystallisation. Filaments thus treated, unlike drawn filaments, do not undergo recrystallisation, even after 1000 hours of incandescence, and crystalline wire, although in the cold softer than drawn wire, becomes rigid at high temperatures.
—F. SODN.

PATENT.

Heat; Process of generating —. W. Thomas and A. E. Mainwaring, Nanaimo, British Columbia. U.S. Pat. 1,221,627, Apr. 3, 1917. Date of appl., Sept. 17, 1914. Renewed Dec. 14, 1916.

A BODY of fuel is coked or charred, and the rich hydrocarbon vapours and gases are withdrawn by means of air at a high pressure and injected at separate localised points into the body of incandescent coke, and into a combustion chamber above the coke. This brings about perfect combustion of the fuel and gases, and causes the mineral matter to be reduced to separate masses of clinker.—J. E. C.

III.—TAR AND TAR PRODUCTS.

Phthalic acid; Salts of —. J. B. Ekeley and C. Banta. J. Amer. Chem. Soc., 1917, 39, 759—768.

THE preparation and composition of a number of phthalates, already described in literature, was verified and the following new salts were prepared: lithium phthalate, $\text{Li}_2\text{C}_8\text{H}_4\text{O}_4$, glucinum (beryllium) phthalate, $\text{BeC}_8\text{H}_4\text{O}_4 \cdot \text{H}_2\text{O}$, manganese phthalate, $\text{MnC}_8\text{H}_4\text{O}_4$, basic ferric phthalate, $\text{Fe}(\text{C}_8\text{H}_4\text{O}_4)(\text{OH}) \cdot 2\text{H}_2\text{O}$, cobalt phthalate, $\text{CoC}_8\text{H}_4\text{O}_4 \cdot 2\text{H}_2\text{O}$, nickel phthalate, $\text{NiC}_8\text{H}_4\text{O}_4 \cdot 2\text{H}_2\text{O}$, acid cerium phthalate, $\text{Ce}(\text{C}_8\text{H}_4\text{O}_4)_3$, mercuric phthalate, $\text{HgC}_8\text{H}_4\text{O}_4 \cdot \text{H}_2\text{O}$, mercurous phthalate, $\text{Hg}_2\text{C}_8\text{H}_4\text{O}_4 \cdot 2\text{H}_2\text{O}$, thorium phthalate, $\text{Th}(\text{C}_8\text{H}_4\text{O}_4)_3 \cdot 5\text{H}_2\text{O}$, and uranyl phthalate, $\text{UO}_2\text{C}_8\text{H}_4\text{O}_4 \cdot 2\text{H}_2\text{O}$. The solubility of these salts apparently bears no relation to the atomic weight of the metallic element present. For instance, the glucinum and nickel salts are very soluble, whilst the lithium and cobalt salts are only slightly soluble; the lead salt is insoluble whilst the thorium salt is moderately soluble. The best method of preparing the salts is by acting on the respective carbonates with phthalic acid solution. A number of the salts were decomposed under varying conditions of temperature and pressure; only traces of anthraquinone were obtained, the main products of the decompositions being resinous matter, phthalic anhydride, and benzophenone, the latter often in large quantity.—W. P. S.

Gas washing [for benzol and toluol]: analysis of products: control of still. Edwards. See IIA.

Potassium persulphate as a reagent in organic chemistry. Datta and Sen. See XX.

PATENTS.

Tar: Distillation of—. B. E. D. Kilburn. London. From Sulzer Frères Soc. Anon., Winterthur, Switzerland. Eng. Pat. 105,198. Sept. 11, 1916. (Appl. No. 12,837 of 1916.)

TAR is distilled in a horizontal drum, the whole of the external surface of which is exposed to the heating gases. The tar from the bottom of the drum is continuously removed by means of one scoop of a series carried on a rotating shaft and deposited on the inner wall of the drum, and is removed therefrom by the next scoop in the series. —F. W. A.

2-Aminoanthraquinone and its derivatives: Production of—. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 295,621. Dec. 21, 1912.

2-AMINOANTHRAQUINONE and its derivatives are obtained by heating 2-chloroanthraquinone, or such of its derivatives as do not contain a strongly negative substituent (e.g., carboxyl, halogen, nitro- or sulpho-groups) in the *ortho* position to the chlorine atom, with aqueous ammonia under pressure, either with or without copper or copper salts. —F. Sp.

3-Nitrocarbazole and its halogen derivatives: Production of—. Act.-Ges. f. Anilinfabr. Ger. Pat. 295,817. Nov. 6, 1912.

3-NITROCARBAZOLE and its halogen derivatives are obtained by treating carbazole or its halogen substitution products with about two molecules of nitric acid of 10% concentration. —F. Sp.

Purification of trade waste effluents [from benzol purification]. Eng. Pat. 104,999. See XIXB.

IV.—COLOURING MATTERS AND DYES.

Phthaleins: New class of—. *Mixed phthaleins formed by heating p-hydroxybenzoyl-o-benzoic acid with phenols.* W. R. Orndorff and R. R. Murray. J. Amer. Chem. Soc., 1917, 39, 679—697.

THE condensation of phenol and phthalic anhydride to give phenolphthalein is considered to take place in two stages, *p*-hydroxybenzoyl-*o*-benzoic acid being the intermediate product. The quantitative formation of *p*-hydroxybenzoyl-*o*-benzoic acid and *p*-aminophenol from phenolphthalein-oxime is explained by the following structure:—

Phenolphthalein and several mixed phthaleins have been synthesised from *p*-hydroxybenzoyl-*o*-benzoic acid. —F. W. A.

Potassium persulphate as a reagent in organic chemistry. Datta and Sen. See XX.

PATENTS.

Sulphide dyestuffs. G. H. Frank. Leeds. Eng. Pat. 105,118. Apr. 3, 1916. (Appl. No. 4817 of 1916.)

NITRO or nitroso derivatives of yacca gum (from *Xanthorrhoea arborea* or *X. hastilis*) or of Congo resin (from *Hymenaea verrucosa* or *Copaifera copallina*) or azo compounds of yacca gum (see following abstract) are fused with alkali sulphides or polysulphides. —F. W. A.

Azo dyestuffs. G. H. Frank. Leeds. Eng. Pat. 105,119. Apr. 3, 1916. (Appl. No. 4848 of 1916.)

YACCA gum (from *Xanthorrhoea arborea* or *X. hastilis*) is combined with diazo or tetrazo compounds, e.g., with diazotised sulphanilic acid in alkaline solution. The product dyes animal fibres yellow shades which may be after-treated with mordants. —F. W. A.

Colouring materials [sulphide dyestuffs]: Method for preparing black—. H. R. Vidal, Asnières, France. Eng. Pat. 105,162. June 26, 1916. (Appl. No. 8988 of 1916.)

BLACK dyestuffs are produced by heating *p*-aminophenol or *p*-amino-*o*- or *m*-cresol with half its weight of resorcinol or *m*-phenylenediamine in the presence of sulphur in such a manner that the vapours produced are condensed and the condensed material flows back into the apparatus. —F. W. A.

Azo dyestuffs: Manufacture of chromium compounds of—containing groups able to be chromated. G. Engi, F. Straub, and A. Grob, Assignors to Soc. Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,221,819. Apr. 10, 1917. Date of appl., July 6, 1916.

Azo dyestuffs containing groups able to combine with chromium are treated with a hot solution of a chromite. —F. W. A.

Dye composition. E. O'N. Macdonald, St. Regis Falls, N.Y. U.S. Pat. 1,222,433. Apr. 10, 1917. Date of appl., Dec. 11, 1916.

A COLOURING matter which dyes wool and silk generally brown shades of good fastness to light and washing, is obtained by extracting the autumnal coloured leaves of a hardwood tree, e.g., brown maple leaves. —F. W. A.

Acyl derivatives of 2.5.7-aminonaphtholsulphonic acid: Production of—. Chem. Fabr. Griesheim-Elektron. Ger. Pat. 295,767. Feb. 5, 1914.

ACYL derivatives of 2.5.7-aminonaphtholsulphonic acid are produced by condensing 2.3-hydroxynaphthoic acid halides, or their *O*-acetyl compounds, with 2.5.7-aminonaphtholsulphonic acid. The products have strong affinity for cotton and silk. 2.3-Hydroxynaphthoyl-2-amino-5-naphthol-7-sulphonic acid gives in alkaline solution the typical yellow colour of the 2.3-hydroxynaphthoic acid arylamino alkali salts. It combines with two molecules of diazo compounds, and is absorbed by cotton from alkaline solutions and by silk from acetic acid solutions. Valuable colours fast to washing are obtained by treating the fabrics with diazo compounds. —F. Sp.

[Azo] dyestuffs: Manufacture of chromium compounds of—. O. Imray, London. From Soc. of Chem. Ind. in Basle, Switzerland. Eng. Pat. 104,045. Mar. 13, 1916. (Appl. No. 3729 of 1916.)

SEE U.S. Pat. 1,221,849 of 1917; preceding.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Marine fibre. D. C. Winterbottom. Dept. of Chem., S. Australia. Bull. No. 4, 1917, pp. 1—36.

MARINE fibre is the resistant skeleton of the leaf sheath of *Posidonia australis*, a sea plant growing in the shallow waters of certain parts of the Australian coast, especially in Spencer's Gulf. The workable beds of fibre attain an average depth of 7 ft., with a yield of about 6 lb. of fibre per cub. yd., and the deposits aggregate approximately 240 sq. miles, with a total estimated yield of

4,600,000 tons. The fibre occurs under a top deposit, 12—18 ins. thick, of living plant; the shallow-draught dredges first clear away this top growth and then collect the commercial fibre for purification. The development work has been conducted by three companies using slightly different methods, and a full description of the development plant in each case is given. The removal of loose impurities (sand, shells, etc.) is effected at sea on the dredge, but in all cases the final cleansing is done on shore, either by crushing and dusting the crude material in the damp or dry state or else, more satisfactorily, by repeated mechanical washings with fresh water. The use of fresh water, however, would be excluded if any large industry were developed and it would be necessary to put on the market a product cleaned with sea water. Much valuable information has been accumulated and the main lines of future development have been determined, but the industry is not yet on a remunerative basis. Marine fibre varies in length of staple from 2 to 8 ins., and the thickness shows extreme variations of 0.02—0.15 mm. It is a brittle fibre and the coarser elements are stiff, like horsehair. It cannot be worked successfully, like jute, on long-fibre combing machinery, but can be carded, though with considerable loss on carding machinery. It can be spun in admixture with jute, and can be batched with the lower grades of wool, for which purpose it is well adapted. Marine fibre has been used for insulation purposes with excellent results and has proved superior to asbestos and charcoal and almost as efficient as wool. For paper making purposes the ultimate fibre would appear to be quite suitable, having a length of 0.02—0.05 in., but the chemical properties of the raw fibre are such that the usual processes of treatment have but little effect. The raw fibre, as might be expected from the conditions of its occurrence, is extraordinarily resistant to rot and chemical hydrolysis; it is a lignocellulose of strongly pronounced type and yields only to the process of chlorination; the percentage of cellulose, 63.6, is relatively low. It is estimated that on an output of 4260 tons per annum, with present methods, the raw dry fibre could be delivered at a European port at a cost of £16 15s. to £19 per ton.—J. F. B.

Paper-yarns in 1916. W. Massot. Z. angew. Chem., 1917, 30, 96—97.

IN recent years the use of paper yarns of 1—5 mm. diam. in the cable industry has largely increased, chiefly as a partial or complete substitute for jute as a packing between the lead sheath and the iron armour of the cables, for which purpose the paper yarns are specially impregnated before spinning. In the coating of lead-sheathed cables with waterproof composition, also, the winding of paper yarn serves as well as the old jute yarn winding, since it adheres better to the lead sheath and blends with the composition to form a perfectly flexible and waterproof covering. Paper yarns spun from parchment paper are used for weaving driving belts for light machines up to about 8 H.P., in widths of 30—155 mm. and thicknesses of 5 and 7.5 mm. The yarns are spun, impregnated, wound on spools, and the fabrics woven from them are stitched together to the required thickness. The effect of treatment with various chemicals has been studied. A solution of aluminium acetate partially neutralised with sodium carbonate imparts a somewhat harsh feel but causes no cohesion of the threads; subsequent treatment in soap solution produces a flexible damp feel and prevents the absorption of water, but does not appreciably improve the strength after immersion in water. Gelatin solution mixed with neutralised aluminium acetate cements some of the threads together and causes a decrease in strength of 17%

but reduces the loss of strength in the wet state. Gelatin mixed with formaldehyde imparts a milder feel and does not cement the threads; in this case the decrease of strength is only 8%, but the loss of strength in the wet state is not reduced to so great an extent. Treatment with 1% tannin solution gives a soft, pliable feel and increases the strength by 49%, and also has a favourable influence on the strength in the wet state. Tannin solution fixed with gelatin gives a hard, string-like feel, increases the strength by 25%, and reduces the loss of strength on wetting to only 15%. Tannin solution fixed with neutralised aluminium acetate gives a strong, elastic feel, the strength is increased by 44%, and the loss of strength in the wet state is 22%. Weaker tannin solutions have a correspondingly weaker effect. Paper yarns come into the market containing a considerable excess of moisture as a residue from the spinning process; this is not necessarily a drawback because the moisture imparts a flexibility favourable to the working up of the yarn into finished goods. The average of a large number of analyses showed a total moisture (natural and excess) of about 38%; the highest value found was 65%. Pinagel (Monatsschr. Text. Ind., 1916, 31, 146) has proposed, as a result of his investigations, that an addition of 14.66% to the dry weight be taken as the basis for the calculation of the commercial weight of paper yarns.—J. F. B.

Methyl alcohol and acetone as by-products of the soda pulp industry. J. C. Lawrence. Met. and Chem. Eng., 1917, 16, 416—417. (See also this J., 1917, 383.)

RINMAN'S process for the distillation of the spent soda liquors with lime is described in its application to esparto liquors. The concentrated black lye is mixed with lime and the mass spread on trays in layers of predetermined thickness. Distillation is carried out in a furnace similar to that employed for the destructive distillation of calcium acetate, the vapours being withdrawn at the coldest part of the furnace and the reaction being assisted by the introduction of superheated steam between the trays so as to sweep the entire length of the retort. The working temperature suitable for maximum yields is 255°—300° C. One of the most interesting products is contained in the "tar." This is esparto wax, which may be separated in a crude state by fractional condensation. A pre-condenser maintained at approximately 200° C. separates the wax from the lighter fractions of the tar; the middle oils are collected in a second condenser at 110° C. and the aqueous vapour containing acetone, alcohol, and ammonia passes through an absorber containing sulphuric acid into the final condenser. The wax is drained and pressed, the ammonium sulphate liquor is evaporated, and the aqueous distillate is rectified, without attempting to separate pure acetone, and sold as "methyl-acetone" or "alcohol-ketone" as a solvent. The following yields are recorded, but on a theoretical basis they should be capable of being increased by 50—75%:—Aqueous distillate, 42.2%; wax and oils, 6.0%; ammonia, 0.3%; residue, 40.7% as black ash only; gas, 10.8%, all calculated on the weight of actual liquor without lime. The spirit content of the aqueous distillate is 5.24%, containing 70% of methyl alcohol and 30% of acetone, ketones, and aldehydes. Of the oily products, 39.2% is condensed at 200° C., as "wax"; 56.5% at 110° C., as "middle oils," and 4.3% passes over as "light oils" with the aqueous distillate.—J. F. B.

Cellulose and chemical industry. Cross. See p. 531.

Action of ozone on organic compounds. [Degradation of sericin by ozone.] Harries and others. See XX.

PATENTS.

Cotton waste; Method of treating — H. S. Landell, Philadelphia, Pa., Assignor to Anglo-American Cotton Products Corporation, New York. U.S. Pat. 1,222,422, Apr. 10, 1917. Date of appl., Sept. 14, 1915.

BOILING caustic soda is circulated through a body of cotton waste; the material is washed and acid is circulated through it. The washed material is subsequently agitated and shredded in the upper portion of a body of water so as to allow the foreign impurities to settle out in the quiescent portion of the water. The sediment is drawn off and the material drained and dried.—J. F. B.

Fabrics and other flexible materials; Impregnating compositions for proofing — L. C. Wooldridge and A. Fox, London. Eng. Pat. 105,137, May 4, 1916. (Appl. No. 6420 of 1916.)

FOR proofing fabrics, e.g., balloon fabrics or wearing apparel, the following composition is employed: pyroxylin, 4 oz., is dissolved in a mixture of 75 fl. oz. of ether and 25 fl. oz. of alcohol. Celluloid, 1½ oz., is added to the solution and when thoroughly dissolved, the mixture is filtered. To the filtrate are added Canada balsam, 13 fl. oz., and castor oil, 9 fl. oz., in which 2 oz. of pure rubber has previously been dissolved.—J. F. B.

Canvas fabrics and the like; Waterproofing and rot-proofing composition for — A. Maltman, Barrhead. Eng. Pat. 104,986, June 21, 1916. (Appl. No. 8724 of 1916.)

A KHAKI-COLOURED proofing composition for canvas fabrics is composed of a mixture of Archangel or other tar, 28 lb., cutch, 7 lb., and cuprammonium solution, 140 galls. The cuprammonium solution contains 1.5% of copper dissolved in ammonia solution of sp. gr. 0.940; the tar, previously mixed with a little strong ammonia solution, is thoroughly incorporated with it in a mixing machine, forming a copper-tar soap, and the cutch then added to develop the colour.

—J. F. B.

Cellulosic materials; Chemical treatment of — M. A. Adam, London. Eng. Pat. 17,846, Dec. 21, 1915.

CELLULOSIC material, e.g., sawdust, wood-waste, or mechanical wood pulp of long fibre, is ground with water to which has been added a hydrolysing acid or bisulphite lye, to form a pulp containing about 90% of water. The pulp is subjected to hydrolysis in a continuous regenerative digester similar to that used for wet carbonising peat, described in Eng. Pat. 17,427 of 1912 (this J., 1913, 1099), the rate of flow through the heating portion of the digester being regulated so that the pulp remains for 30–40 mins. at the predetermined digestion temperature, e.g., 150° C.; the pulp is then caused to transmit a portion of its heat to the incoming fresh material, so that the digested pulp is discharged at a temperature suitable for filtration, e.g., 80–95° C. The liquid is separated from the solid material also in a continuous manner, e.g., by means of an endless travelling web combined with suction-boxes and press-rolls. The process is applicable to the manufacture of chemical wood pulp from ground wood and to the production of alcohol from the hydrolysed material.—J. F. B.

Fibrous material [waste paper]; Process and apparatus for separating — from impurities and recovering the fibres. N. V. Neo-Cellulose Maatschappij, Rotterdam, Holland. Eng. Pat. 104,952, Apr. 25, 1916. (Appl. No. 5938 of 1916.) Under Int. Conv., Apr. 1, 1916.

THE disintegrated fibrous material suspended in liquid is discharged on to the inner surface of a

rotating drum designed to impart a rotational and progressive movement to the material by means of conveyor blades depending from the axis. The feed end of the cylinder may have solid walls, but the remainder is constructed of wire gauze in order to drain away the liquid, and after the material has assumed the form of a rolling coherent mass with progressive movement, sprays of washing liquid are directed on this mass at a high velocity from an axial supply pipe, the liquid percolating away at a low velocity. External sprays are fitted above the upper portion of the drum to keep the meshes clear of deposit.—J. F. B.

Vulcanised fibre [leather substitute]; Treatment of — T. Oye, Christiania, Norway. Eng. Pat. 105,033, Oct. 6, 1916. (Appl. No. 14,234 of 1916.)

PLATES of hard vulcanised fibre, 1–6 mm. thick, are steeped in a solution of zinc chloride (1:5), dried in the air, impregnated with an emulsion of water and oil at 20–50° C. and subsequently with an animal or vegetable oil at a low temperature. The excess of oil is wiped off and the plates dipped in a bath of melted paraffin wax or in a solution of water-glass. The treated plates are flexible and capable of being used as a substitute for sole-leather.—J. F. B.

Pulp digesters; Sampling device for — P. S. Tuttle, Johnsonburg, Pa. U.S. Pat. 1,222,249, Apr. 10, 1917. Date of appl., July 31, 1916.

Fur; Process for treating — W. P. Braun, Brooklyn, N.Y., U.S.A. Eng. Pat. 105,508, Oct. 10, 1916. (Appl. No. 14,408 of 1916.)

SEE U.S. Pat. 1,215,246 of 1917; this J., 1917, 334.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Dyeing yarn in the form of skeins; Machine for — B. E. D. Kilburn, London. From Sulzer Frères Soc. Anon., Winterthur, Switzerland. Eng. Pat. 105,015, Aug. 12, 1916. (Appl. No. 11,423 of 1916.)

IN a machine for dyeing yarn in the form of skeins in small quantities, the yarn reel is not itself eccentrically mounted, but is driven by an eccentric or cam or by means of friction or toothed wheels in such a manner that it is given a periodical movement in a vertical plane without lateral movement and is also rotated first in one direction and then in the other, to ensure all the portions of the yarn skeins being dipped for the same length of time, at a speed which varies continually during each period to prevent the yarn from tangling. The combination of the two motions has for its object a temporary loosening of the skein layers, which results in satisfactory penetration being attained.—F. W. A.

Warp printing machines. J. Zimmermann, Philadelphia, Pa., U.S.A. Eng. Pat. 104,953, Apr. 25, 1916. (Appl. No. 5939 of 1916.)

IN warp printing machines of the type in which the warp threads are situated above the printing rolls, pattern-controlled impression members being pro-

vided for bringing the warp threads into contact with the rolls, the printing rolls are partially submerged in the colouring matter and a device is provided for evenly distributing the colouring matter regardless of any inequality in the surface of the printing rolls.—F. W. A.

Warp threads; Apparatus for washing — after printing. J. Zimmermann, Philadelphia, Pa., U.S.A. Eng. Pat. 105,209, Apr. 25, 1916. (Appl. No. 17,205 of 1916.)

AN apparatus for washing warp threads after printing and/or steaming consists of a number of independent washing pans with intermittently operated means for immersing the threads, consisting of arms normally disposed over the threads and movable into engagement with them, jets for directing a blast of air against the threads, to remove surface water, and a drying chamber. Owing to their course of travel through the pans being constantly changed, thorough washing of the threads is facilitated.—F. W. A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Application of the Komarowsky reaction as a test of purity of concentrated —. Mitt. aus dem Lab. der Schweiz. Alkoholverwaltung. Chem.-Zeit., 1917, 41, 132.

SULPHURIC acid sold as "pure for analysis" is commonly unsatisfactory for the testing of alcohol for higher alcohols by the Komarowsky reaction on account of the presence of organic matter. It is suggested that this reaction should be applied in selecting acid to be used in laboratories for the testing of wines and spirits, and that acids not giving a negative result should be rejected. The specification of the reaction in Switzerland is as follows:—10 c.c. of spirit is placed in a stoppered flask of 100—150 c.c. capacity, and 1 c.c. of a 1% solution of salicylic aldehyde in purest alcohol and 20 c.c. of pure sulphuric acid are added. The whole is mixed by shaking. Pure reagents give only a light yellow colour. Organic impurities in the acid cause a dark yellow to brown colour and oxides of nitrogen a pink colour. The sulphuric acid can be purified by heating it with 0.2—0.3 gm. potassium bichromate per kilo. of acid.

—H. J. H.

Sulphuric acid; Determination of small amounts of free — in presence of sulphates. E. Vulquin and M. Entat. Ann. Chim. Analyt., 1917, 22, 61—66.

VERY small quantities (0.0004 gm.) of free sulphuric acid can be determined in presence of sulphates, of organic acids, and of inorganic and organic salts, by measuring the fall of potential between a normal calomel electrode and a polarised platinum electrode placed in the solution, at intervals during the neutralisation of the acid with a standardised baryta solution. A curve is plotted co-ordinating the amounts of baryta added with the differences of potential recorded, and the complete neutralisation of the free acid is indicated on the curve by a sudden change of direction. The platinum electrode is sealed in a glass tube filled with mercury and is rotated by means of a small electric motor at the rate of 100—300 revolutions per minute. The calomel electrode is placed in a separate vessel, and communication between the solutions is effected by means of a tube with two rectangular bends filled with starch paste saturated with potassium nitrate. The polarising

current should not exceed 1.2×10^{-4} amp. and the E.M.F. is found by Poggendorff's compensation method with an Ostwald capillary electrometer. As the volume of solution should be as far as possible constant, the solutions should be concentrated, and the baryta added from a 1 c.c. or 5 c.c. burette. Trial determinations on solutions containing 0.0041—0.0073 gm. of free sulphuric acid, and on a solution containing 0.00565 gm. of acid in presence of acetic acid, calcium sulphate, magnesium sulphate, potassium chloride, and potassium nitrate, gave very accurate results.

—E. H. T.

Oxalic acid; Titration of — with alkalis and ammonia in presence of methyl orange. G. Bruhns. Chem.-Zeit., 1917, 41, 189.

OXALIC acid can be determined directly by adding alkali until it is nearly neutral, then introducing at least an equivalent of calcium chloride (or of certain other neutral metallic salts), whereby calcium oxalate is precipitated and hydrochloric acid set free, and finishing the titration in presence of methyl orange. Other organic acids, e.g., tartaric and citric acids, may be determined in a similar way. In the presence of calcium chloride, oxalic acid and ammonia solutions can be titrated directly, loss of ammonia being prevented by adding to the *N/10* solution, a solution of borax containing 35—40 grms. per litre. This method has been used successfully for nine years. Similarly, oxalic acid and borax solutions can be accurately titrated when calcium chloride is added just before the neutral point has been reached. Correct results are also obtainable when oxalic acid solutions are titrated in presence of phenolphthalein, provided that distilled water perfectly free from carbon dioxide be employed. Many years' experience has shown that oxalic acid crystals remain perfectly stable for a very long time. On one occasion very small crystals were maintained for several days in open vessels at 30°—32° C. without any perceptible change in weight.—E. H. T.

Hydrochloroplatinic acid; Preparation of — by means of hydrogen peroxide. P. Rudnick and R. D. Cooke. J. Amer. Chem. Soc., 1917, 39, 633—635.

PLATINUM black, if it has not been ignited, dissolves readily in concentrated hydrochloric acid in the presence of hydrogen peroxide, yielding hydrochloroplatinic acid which is entirely free from nitro-compounds and from hydrochloroplatinous acid, both of which affect its value as a reagent. It is necessary to regulate the addition of the peroxide to avoid frothing.—W. H. P.

Ammonia; Synthesis of —. H. Le Chatelier. Comptes rend., 1917, 164, 588—590.

THE fact that ammonia could be synthesised by heating nitrogen and hydrogen together under pressure was discovered by the author in 1901, but owing to a nearly fatal explosion the investigation was abandoned. Seven years later, the work was resumed by Haber, who brought it to a successful issue. This research (and others) was undertaken with the object of convincing chemists of the great possibilities that would attend the application of thermo-dynamical principles to chemical change, and the possible industrial application of the discovery was covered by a patent (Fr. Pat. 313,950, Sept. 2, 1904) which, however, was allowed to lapse. According to it, ammonia was produced by heating nitrogen and hydrogen, with or without the addition of hydrocarbons, under pressure and to a temperature above a dull red heat, in the presence or absence of spongy platinum or of finely divided iron.—E. H. T.

Bleaching powder; Manufacture of— in chambers or with mechanical apparatus. E. Schütz. *Chem.-Zeit.*, 1917, 41, 137—140.

THE question of the relative merits of absorption chambers and mechanical apparatus has recently been put to the test in many new installations. The only important sources of the chlorine are the electrolytic product which contains about 99% Cl and that derived from the Deacon process which contains an average of 8% by volume of the halogen. The chamber process is the less healthy for the workers, requires rather more labour, and demands much more space than its rival which, in its turn, necessitates a more skilled supervision. For a plant to produce 20 tons (metric) of bleaching power in 24 hours, at least four chambers are required, one-half being filled while the other half is being emptied; for the working of this 6 men and 1 boy are necessary. A mechanical plant of the same capacity would consist of 10 units each composed of 8 superimposed cylinders, and require the labour of 5 men and 1 boy (subsidiary operations, as, e.g., the slaking of the lime, are not included, being the same for both processes). To produce the above yield the chambers would cover an area of at least 2400 sq. m., the mechanical plant about 250 sq. m. The capital cost is probably somewhat in favour of the mechanical method. The modern absorption chamber is made of lead mounted on a wooden framework, after the manner of the sulphuric acid chamber, and is about 7 ft. high. The floor is made of lead covered with flag-stones set in asphalt, the joints being made with a cement of litharge and glycerin. The walls, up to a height of 50 cm., are faced with granite slabs joined together with the same material. The chlorine is introduced through earthenware socket-pipes and where a number of chambers are used, a high chimney must be provided for the exit-gases. With electrolytic chlorine, the passage of the gas into the chamber has to be assisted by a ventilator-fan, made of lead or earthenware and preferably faced with ebonite. The mechanical apparatus is made of cast-iron covered with acid-resisting material. The most common form contains 8 cylinders of such a diameter that a maximum of 2—2.4 tons of product can be obtained in 24 hours. The mechanical means of conveying the lime through the cylinders have been improved, the blades now being made of stronger material and fixed to a four-edged shaft by a kind of bayonet attachment. The cylinders require cleaning out once daily. A satisfactory mechanical method of filling the upper cylinders has yet to be found. It is essential that the chlorine be dry and as free as possible from other gases, particularly from carbon dioxide. Electrolytic chlorine contains much more of the latter than the gas supplied by Deacon's process; its amount must be reduced to a maximum of 2% for the chamber method and must not exceed a few tenths of 1 per cent. for the mechanical plant. The careful adjustment of the ratio of chlorine to air is of the first importance in the mechanical process, and this is not easy when the electrolytic gas is used; in this case the mixed gases may contain from 10—12% of chlorine, and it is advisable to mix the gases in a special mixing chamber. The current of gases passing through the cylinders must be regular and of constant composition, and a second ventilator-fan should be installed between the cylinders and the chimney. Attempts to free the gaseous mixture from water by cooling to 0°C. have not been an economic success, hence it is still dried by contact with 92—93% sulphuric acid in a leaden tower. For a yield of 20 tons per 24 hours, a tower measuring 9—10 × 2 m. is required. The acid is used continuously until its concentration is reduced to 58°—59° B. (sp. gr.

1.67—1.69), and the water-content of the gas is gauged from the temperature in the tower. Moist chlorine is particularly objectionable in the mechanical apparatus as it leads to a rise in temperature and decomposition of the bleaching powder. The lime is slaked in a mechanical apparatus and allowed to cool for several days before it is sifted and used in the plant. It should contain about 5—6% of free water for use in the cylinders, and 1% when destined for the chambers. With efficient working, the waste gases should not contain more than 0.1% of chlorine, and their temperature should not exceed 38°—42°C. When electrolytic chlorine is used, its content of carbon dioxide must be regularly determined, the gasometric method with stannous chloride solution being preferred. The finished product should contain about 40% of available chlorine, thus allowing for a loss of 1% during transit and a loss of 1—1.5% owing to formation of calcium chloride, which is particularly noticeable in the mechanical method. The view is expressed that the mechanical apparatus will in time entirely supersede the absorption chamber.—E. H. T.

Hypochlorite; Conversion of— into chlorate in alkaline solution. F. Förster and P. Dolch. *Deutsche Bunsen-Ges.*, Dec., 1916. *Chem.-Zeit.*, 1917, 41, 10.

AN experimental study of the conversion of sodium hypochlorite into sodium chlorate in alkaline solution showed that two successive reactions are involved:—(1) $2\text{NaClO} = \text{NaClO}_2 + \text{NaCl}$, and (2) $\text{NaClO} + \text{NaClO}_2 = \text{NaCl} + \text{NaClO}_3$. Only a small proportion of chlorite was detected in the solution, but this is accounted for by the relatively high velocity constant of the second reaction, which is 26—35 times that of the first. In acid solution (e.g., with an excess of chlorine) it is supposed that chlorate is formed directly, according to the equation, $\text{NaClO} + 2\text{HClO} = \text{NaClO}_3 + 2\text{HCl}$, which explains the more rapid conversion experienced under these conditions. No chlorite was formed during the electrolytic production of chlorate from pure chloride solution, and added chlorite was quickly converted into chlorate by anodic oxidation.—F. SODN.

Perchlorate; Electrolytic formation of—. E. L. Mack. *J. Phys. Chem.*, 1917, 21, 238—264.

THE formation of perchlorate by the electrolysis of chlorate is generally regarded as a secondary action following the liberation of the chloric acid anion as expressed by the equation:— $2\text{ClO}_2' + \text{H}_2\text{O} = \text{HClO}_4 + \text{HClO}_2$. An alternative theory that the formation of perchlorate arises from the direct addition of oxygen to the chlorate is more in accordance with the following observed phenomena:—Through the operation of over-voltage the potential necessary to separate oxygen in the free condition depends on the material of the anode. With an iron anode, it was found that the formation of perchlorate begins at a potential far below that required for the liberation of oxygen, and nearly as far below that commonly assigned for the discharge of ClO_2' . The high efficiency in the formation of perchlorate when a strong neutral chlorate solution is electrolysed with a platinum anode is due to the high concentration of atomic oxygen which follows from the high overvoltage. On lowering the current density, the efficiency falls in proportion to the diminution of the overvoltage. If the temperature is raised the current efficiency decreases markedly, which is in accordance with the view that the concentration of active oxygen present at the anode is dependent on the state of the reaction, $2\text{O}_1 = \text{O}_2$, which increases in velocity with increased temperature. It was also found that the inhibiting effect of high temperature

can be overcome by an increase in the current density. With an alkaline solution, the current efficiency falls off rapidly owing to the discharge potential for oxygen on platinum being lower in alkaline than in acid solutions, thus leading to a lower concentration of active oxygen. On starting the electrolysis both the potential of the anode and the efficiency are somewhat below their normal values, which would be expected from the fact that the measurements of anodic overvoltage indicate a low concentration of active oxygen during the first few moments of oxygen discharge. The decrease in anodic efficiency on substituting an anode of platinised platinum for one of polished platinum agrees with the view that at a given current density, the concentration of active oxygen at a platinised anode is less than with the smooth metal. In general, any factor which tends to lower the concentration of active oxygen at the electrode affects unfavourably the formation of perchlorate. The oxidation of chlorate to perchlorate can be brought about chemically by heating the solid with silver oxide or to a small degree in aqueous solution by persulphuric acid, ozone, hydrogen peroxide in acid solution, and by oxygen which has been activated by ultra-violet light, thus supporting the view that the electrochemical formation of perchlorate is the result of direct oxidation.—J. N. P.

Potash salts, original liquors, and end liquors: The bromine contents of German —. L. W. Winkler. *Z. angew. Chem.*, 1917, **30**, 95–96.

THE German potash liquors contain considerable quantities of bromine, amounting to 7.492 grms. for Stassfurt, 5.398 for Mecklenburg, and 3.691 for Hainleite, per litre in original liquors of approximately 1.3 sp. gr. The end-liquors from Stassfurt contain 3.850 grms., mother-liquors from Alsace sylvinite 4.907, and end-liquors from Sondershausen 2.865 grms. per litre. The percentages of bromine in the commercial potash salts show considerable variations: bischofite and tachhydrite from Vienenburg are the richest, with 0.467% and 0.438% respectively; carnallite shows 0.143–0.356%, sylvinite 0.117–0.300%, and sylvinite 0.085–0.331%; "Hartsalz" contains only 0.027–0.052%, and langbeinite only 0.016%. Br.—J. F. B.

Sodium sulphite: Effect of various substances on the photochemical oxidation of solutions of —. J. H. Mathews and M. E. Weeks. *J. Amer. Chem. Soc.*, 1917, **39**, 635–646.

THE authors have studied the phenomenon of negative catalysis, using ultra-violet light from a quartz mercury-vapour lamp. In their apparatus the reaction was rapid, a 0.2 N solution of sodium sulphite being completely oxidised in three hours. All the organic substances used as catalysts had an inhibiting effect, that of urea, however, being very slight. The most marked effects were obtained with pyridine (5 c.c. per litre), benzaldehyde (5 drops per litre), and quinine sulphate (0.001 N), while methyl and ethyl acetates (5 c.c. per litre), phenol (0.001 N), quinol (0.001 N), and sucrose (0.025 N) were less effective. The effect produced by glycerol (5 drops per litre) was only small, although this substance is a powerful inhibitor of the oxidation in ordinary light. Copper sulphate, which is a powerful positive catalyst in ordinary light, is practically without effect in ultra violet light.—W. H. P.

Lead: Attempt to separate the isotopic forms of — by fractional crystallisation. T. W. Richards and N. F. Hall. *J. Amer. Chem. Soc.*, 1917, **39**, 531–541.

ABOUT 1 kilo. of radioactive lead from Australian carnotite, which, from measurements of the β -ray

activity, was inferred to contain about one part of ordinary lead to 3 of radium G, and an amount of radium D of the order of 10^{-7} part, was converted into the nitrate and repeatedly crystallised from aqueous solution. After a thousand fractionations, samples were taken from the most soluble and least soluble fractions respectively, carefully purified, and used for determinations of the atomic weight of the lead. The average atomic weights obtained for lead from opposite ends of the fractionation were 206.422 and 206.409 respectively, or a difference of only 6 parts in 100,000. On the assumption that the atomic weights of radium G and lead are 206.0 and 207.2, it follows that no change in the relative concentration of the isotopes greater than 1.1% had been effected by 900 crystallisations. The change in the relative concentration of radium D produced by the fractionations was also within the same limits.—J. N. P.

PATENTS.

Hydrochloric acid; Manufacture of —. J. B. Garner and H. D. Clayton, Pittsburgh, Pa., Assignors to Metals Research Co., New York. U.S. Pat. 1,220,411, Mar. 27, 1917. Date of appl., Mar. 4, 1915.

A MIXTURE of moist hydrogen and chlorine, in the volumetric ratio of about 50:35, is heated to a temperature not below 340° C. in the presence of wood charcoal, and the hydrogen chloride produced is absorbed in water.—E. H. T.

Sulphuric acid; Manufacture of —. W. J. Kee, jun., Kansas City, Kans., and U. Wedge, Ardmore, Pa. U.S. Pat. 1,220,752, Mar. 27, 1917. Date of appl., Aug. 8, 1914.

IN the manufacture of sulphuric acid by the chamber process, the mixed sulphur dioxide and oxygen are exposed to an electric discharge after leaving the Glover tower and before entering the lead chamber, or at other points between the Glover and Gay-Lussac towers. By subjecting the nitrogen oxides as they are formed at the temperature of the electric arc to sulphuric acid at a temperature suitable for their absorption, their reversion to nitrogen and oxygen is prevented.—E. H. T.

Ammonia; Manufacture of —. A. Classen, Aachen, Germany. Eng. Pat. 14,055, Oct. 4, 1915.

NITROGEN and hydrogen are subjected to the simultaneous action of silent and spark electric discharges in presence of catalysts, e.g., metals and metallic alloys, supported on carriers of an acidic nature. Silica, prepared from water-glass, is well suited for this purpose, as it readily adsorbs colloidal metals such as gold, platinum, metals of the platinum and iron groups, as well as their alloys. The efficiency of the catalyst is improved by the presence of a protective colloid, e.g., gelatose. The mixed gases are passed over the catalyst between two electrodes, one being a good

conductor, like copper, and the other a bad conductor, like glass or porcelain. The latter may be immersed in cold water and may concentrically surround the former, the contact material being in the intervening space. The temperature may range from 25° C. to 90° C. according to the conditions, and the pressure may be normal or increased.—E. H. T.

Sulphate of ammonia; Method of, and apparatus for, producing —. Riter-Conley Manufacturing Co., Leedsdale, Pa., U.S.A., Assignees of H. A. Carpenter, Sewickley, Pa., U.S.A. Eng. Pat. 104,155, Mar. 17, 1916. (Appl. No. 4000 of 1916.) Under Int. Conv., Feb. 15, 1916.

COAL gas is passed into a saturator containing sulphuric acid kept at uniform temperature, volume, and concentration, and as it emerges its heat is utilised to control the temperature of the incoming gas. The separated sulphate, as it is withdrawn, is washed by meeting a counter-current of water, which is then used to maintain the volume of the liquid in the saturator. The sulphate is removed by an endless bucket conveyor mounted on a rotating support and adapted to remove material from different parts of the accumulation. Connected with the saturator is a second vessel provided with a pump by means of which acid is forced into the first vessel below the liquid surface, and the acid is kept in circulation; the strong acid required to maintain the acidity of the bath is supplied to this auxiliary vessel. By means of electrical and mechanical devices the movements of a float or hydrometer in the auxiliary vessel are made to control the supply of water and of strong acid and thus ensure the level and the acidity of the liquid in the saturator remaining constant.—E. H. T.

Ammonium chloride; Preparation of —. H. Precht, Hanover, Ger. Pat. 295,509, June 23, 1915.

AMMONIUM magnesium chloride or magnesium chloride is decomposed in aqueous solution with an excess of ammonia, the precipitated magnesium hydroxide filtered off, and the filtrate again treated with ammonia, the operations of filtering and introducing ammonia into the filtrate being repeated until a sufficient yield of ammonium chloride is obtained. With magnesium chloride, 70-80% is decomposed after the second precipitation. The double salt may also be decomposed by treating with a large excess of ammonia in a closed apparatus, under pressure.—F. SODN.

Nitric oxide; Production of — in internal combustion engines. E. C. R. Marks, London, From E. Wuest, Saarbrücken, Germany. Eng. Pat. 104,734, Mar. 15, 1916. (Appl. No. 3878 of 1916.)

THE conditions of chemical efficiency in the internal combustion engine are very different from those determining thermal efficiency. The rapidity of combustion of the gases is accelerated by preheating them, and the higher the temperature of the charge the more rapid the fall of temperature afterwards. The mixed oxygen and nitrogen are agitated energetically during compression by passing a jet of gas, steam, or air at high velocity, and preferably under pressure, into the combustion chamber; and the residual gases are eliminated quickly by a current of warm or cold air.—E. H. T.

Aluminium carbide; Art of producing —. M. Barnett and L. Burgess, New York. U.S. Pat. 1,219,797, Mar. 20, 1917. Date of appl., Dec. 18, 1916.

ALUMINA and carbon are heated together in an electric furnace to a temperature below that of the electric arc but not below 2000° C. The

amount of carbon used is in excess of that required to reduce the alumina to metal, e.g., 1 part of carbon to 2 parts of alumina.—E. H. T.

Silicides and borides of tungsten; Manufacture of —. E. Wedekind, Strassburg, and J. Pintsch A.-G., Berlin. Ger. Pat. 295,547, Nov. 23, 1913. Addition to Ger. Pat. 294,267 of 1913 (this J., 1916, 1156).

THE components are compressed into rods and subjected to electrical resistance heating in a vacuum. The rods may be held in the furnace between clips which are connected with a source of current at not less than 100-130 volts. The resistance of the rods, at first fairly high, suddenly falls, and the reaction sets in with incandescence.—F. SODN.

Air; Process and apparatus for liquefying atmospheric — and separating it into its constituents, oxygen and nitrogen. J. F. Place, Glen Ridge, N.J., U.S.A. Eng. Pat. 105,106, Mar. 29, 1916. (Appl. No. 4633 of 1916.)

TWO portions of the air are compressed to different degrees, one to a pressure much higher than its critical pressure and the other substantially to its critical pressure. The air at the higher tension is then cooled in accordance with the Joule-Thomson formula, by reducing its pressure in successive steps through a throttled valve, the liquefied air, as produced, being caused to descend by gravity through and in rectifying contact with an ascending column of cold gaseous air, from some external source. The heat of compression, the carbon dioxide, and most of the moisture must be removed from the compressed air before the release of pressure takes place, and the expanded air is then employed to cool and liquefy the other portion of air compressed to a lower degree. A pressure of 200 atmospheres is employed for the high tension air, and one of 40 atmospheres for the remaining air.—J. B. C. K.

[Sulphuric acid] chambers; Density-regulator for the atomising of water under pressure and of steam in lead —. L. Santa, Turin, Italy. U.S. Pat. 1,221,913, Apr. 10, 1917. Date of appl., Aug. 21, 1913.

VIII.—GLASS; CERAMICS.

Fireclays; Do — contain halloysite or clayite? J. W. Mellor. Trans. Ceram. Soc., 1916-17, 16, 73-84.

A CRITICISM of a hypothesis by Le Chatelier in 1887 and by J. W. Gregory and D. P. McDonald in 1910 that sedimentary clays and particularly Glenboig fireclays contain amorphous halloysite. The author gives the heating curves of crystalline kaolinite, fireclay, halloysite, silicic acid, allophane, and pyrophyllite and shows that halloysite and

kaolinite are readily distinguishable by this means, as halloysite has no critical point at 500° C. The heating curve of halloysite is not characteristic, since allophane and several other hydrated alumina-silica minerals (which are probably mixtures of colloidal alumina and colloidal silica) give similar curves. It is concluded that the dominant mineral in Glenboig fireclay is clayite—a colloidal form of kaolinite. The same is true of Stourbridge, Lancashire, and most other fireclays and also of Devon and Dorset ball clays, though in ball clays there is also evidence of some kaolinite.

—A. B. S.

Fireclay and similar articles; New process of manufacturing — B. J. Allen. Trans. Ceram. Soc., 1916—17, 16, 134—157.

CASTING large or thick-walled articles made of fireclay has not hitherto been wholly satisfactory. If the slip is poured into a mould with two plaster faces, the centre of the casting is seldom solid, whilst if a liner of cast clay is fixed in a mould and the final form is cast around it, a laminated structure is produced. These objections are overcome by surrounding a simple one-face plaster mould with an iron case and removing the air between the mould and casing. This enables the filtering power of the mould to be increased to an almost unlimited extent, and a deposit of clay of any reasonable thickness can be obtained. The deposit is homogeneous, without any hard skin and soft core; it is in closer contact with the mould than when no suction is used, and the danger of collapse is eliminated, as the low pressure may be maintained until the article is hard and self-supporting. When one part of the article is required to be thicker than another, the space between the case and the mould is increased and *vice versa*. Illustrations and brief descriptions of this method of casting large vessels, glass-house pots—both open and covered—chemical ware, condensing worms, and insulators are given. "Electro-deposition" of flint, clay, plumbago, etc., is suggested for making tubes. The material, made into a slip with a little caustic soda, is allowed to flow through a mould encased in type metal and with a brass rod running through its centre. An electric current is then passed through the slip, using the case and rod as electrodes. The material is deposited and water flows away. A combination of the two preceding processes suitable for the production of plumbago crucibles and muffles, carborundum articles, etc., is also described. In using this, to make two-necked jars, the metal case surrounding the mould forms one electrode and the other is formed by a suspended, perforated metal tube inserted through each neck. The mould is kept full of slip and on passing the current, the suspended material migrates to the case and the water accumulates around the suspended tubes and may be siphoned off through insulated pipes which are used to carry the current to the suspended electrodes. When the deposit is sufficiently thick, the remainder of the slip is siphoned off, and a vacuum is created between the mould and the outer case, to extract the remaining liquid. The density of the deposit may be increased by employing a higher voltage. The reversal of the current may be used to release the material from the mould. When a dense slip is used, the plaster mould and vacuum are unnecessary and a simple metal mould will suffice.—A. B. S.

Furnace linings [for the iron and steel industry]; Acid and basic — J. E. Foster. Trans. Ceram. Soc., 1916—17, 16, 24—39.

REFRACTORY materials are used in constructing blast furnaces, puddling furnaces, cupolas, Bessemer (acid) converters, basic converters, open hearth, electric, and crucible furnaces. The bricks and

blocks used for such purposes should be infusible at 1400° C., becoming hard and dense, but somewhat porous; they should resist chemical reagents, show only a small change in volume at 1100° C., and be unaffected by temperature changes. *Fireclay furnace bricks* are made of a mixture of lean and plastic clay and grog, which is ground, tempered, and then ground wet in a pan-mill. The clay is shaped by hand in wooden or iron moulds or in hand-presses, or it may be pressed hydraulically. The bricks are partially dried by steam or hot air and are then re-pressed. When fully dried, they are burned up to cones 14—16 (1410°—1460° C.), about a week being required. *Silicious furnace bricks* are made of ganister, quartz, flint, and quartzite (sandstone), with or without a proportion of old bricks and a bond of milk of lime, fireclay, or iron oxide. The materials are ground and tempered in a wet pan-mill and are shaped in iron or wooden moulds or in a power-driven press. The bricks are dried and then burned in round kilns up to 1400°—1600° C., from 7 to 10 days being required. The cooling must be slow above 700° C. or the bricks will crack. *Magnesia furnace bricks* are made of selected, calcined magnesite which is ground to 0.1 in. and treated in a similar manner to silica, though the burning temperature reaches cone 18—30 (1500°—1670° C.). *Chrome bricks* are made of low-grade chromite. They cannot safely be used above 1500° C. on account of disintegration. They are used chiefly as a buffer between magnesia bricks and the bottom of the furnace. The ore is crushed in a stone-breaker, then ground in an edge-runner and finally in a tube-mill, the bond being added previous to the final milling. The bricks are made in power-driven presses, dried, and burned in chamber kilns at cone 12 (1350° C.). They swell if burned too rapidly. A classification of furnace bricks according to their refractoriness, porosity, tensile strength, and resistance to crushing and to slag is suggested.

[Pottery] frits; Effect of water on — during wet grinding. J. W. Mellor. Trans. Ceram. Soc., 1916—17, 16, 67—68.

WHEN a certain alkali-lime-boric frit was heated in the usual manner, it developed blisters. These were found to be due to 5.41% of water which entered into combination on grinding the frit in a wet state. When dry ground, this frit gave no trouble. B. Moore had previously noticed this phenomenon with other frits containing alkali.

—A. B. S.

[Lime-] earthenware; Manufacture of cheap — A. Teichfeld. Trans. Ceram. Soc., 1916—17, 16, 1—15.

THE author describes the manufacture of earthenware containing lime in Russian Poland and South Western Russia, and suggests its production in England as a means of meeting German competition in the cheaper kinds of pottery. The earthenware is made of Vistula sand 11—42 parts, Kieff kaolin 27 parts, Donetz ball clay 27—56 parts, and a very pure limestone from S.W. Poland 6 parts. Part of the Russian ball clay may be replaced by a silicious ball clay from Meissen; this prevents crazing. To the ball clays, a little soda and a large quantity of water are added, and the mixture is blunged and then passed through an 80's lawn. The sand and limestone are ground in a tube-mill for 16 hours and all the materials are then mixed. The resulting slip is passed through a 120's lawn and an electro-magnetic machine and is then used for casting, or it is flocculated by the addition of calcium chloride solution. The articles are shaped in the ordinary manner and are burned in saggers in down-draught ovens to about cone 3a (1140° C.)

in 15–18 hours. The biscuit ware is then dipped in a plumbiferous borocalcite glaze corresponding to the formula: $(\text{PbO } 0.342, \text{CaO } 0.378, \text{Na}_2\text{O } 0.135, \text{K}_2\text{O } 0.145) \text{Al}_2\text{O}_3 \text{ } 0.218 (\text{SiO}_2 \text{ } 2.68, \text{B}_2\text{O}_3 \text{ } 0.28)$. Of this glaze, 48% is in the form of a frit. The glaze is fired at cone 1a (1100 °C.) in 12–15 hrs. The finished ware is about 10% lighter than English earthenware and is cheaper to produce.—A. B. S.

Porcelain; Electrical — L. E. Barringer. Met. and Chem. Eng., 1917, 16, 433–436.

PORCELAIN has superseded other materials for the insulation of overhead lines and purposes where high weather-resistant insulation is required. It has a high dielectric strength, and a $\frac{1}{4}$ in. thickness will usually not puncture under 70,000 volts, or a $\frac{1}{2}$ in. thickness under 100,000 volts. The dielectric strength begins to fall at 100° C., and at 300° C. the insulation is very poor. Electrical porcelain has sp. gr. 2.4 and coefficient of expansion 0.000004 per 1° C.; the crushing strength averages 20,000 lb. per sq. in. and the tensile strength 900–1800. Porcelain, however, is deficient in toughness and does not withstand sudden shock or impact or even vibration. There is also little or no resistance to sudden changes of temperature; it has no flexibility and cannot be used in moving elements subject to bending or torsional strain. There is also the drawback that metal parts cannot be embedded or moulded into place on account of the necessity for firing. The materials used for the manufacture of electrical porcelain are china clay, ball clay, feldspar, and silica. The clays possess the advantage of plasticity, but when used alone, a porous mass or "body" is obtained unless the firing heat is so excessive that fusion or distortion occurs. Feldspar is used as a flux to give a dense vitrified body at a moderate temperature, and flint as a stabiliser to extend the vitrifying range and to prevent distortion within a narrow temperature range. Between 600° and 900° C. the clay loses its combined water; at about 1200° C. the feldspar fuses and the clay begins to dissociate with formation of sillimanite; at a higher temperature the quartz is slowly attacked and finally dissolved in the feldspar at 1400° C. The ware is classified according to the dry or wet processes. Dry process porcelain is formed in steel dies and is used for low-voltage insulation, being more porous and of lower dielectric strength than the wet process ware; dry process porcelain will absorb 1% of water when immersed, whereas the wet process porcelain absorbs only 0.25%. The process of drying and burning electrical porcelain is much the same as for any other type of porcelain, but the old bottle-shaped potters' kiln is uneconomical. A continuous kiln is described which saves about 50% of the fuel-cost. It consists of a straight tunnel, 197 ft. long, with fixed firing zone somewhat nearer the discharge end than the entrance. The ware is placed on cars and moved through the firing zone to the cooling end. At the firing zone there are grates on either side. The combustion chamber is separated from the main tunnel by a narrow wall and the gases are passed through tuyères before entering the main tunnel. Air for combustion is preheated by passing through holes at the discharge end and coming in contact with the cars of goods cooling off. Just before reaching the firing zone part of the air is deflected beneath the grates and another part is directed into the main tunnel at the firing zone to complete the combustion of the gases from the fire-boxes; it then passes on towards the entrance to heat the incoming cars. The firing temperature is 1300°–1400° C. and the temperature at the chimney only 200°–220° C.

—J. F. B.

Discolorations in the manufacture of pottery and bricks. B. Moore and J. W. Mellor. Trans. Ceram. Soc., 1916–17, 16, 58–66.

THE work of Seger, Sosman and Merwin, Brongniart, Jackson and Hopwood, Orton and others is reviewed, and the reddening of buff and white bodies is attributed to the formation of free ferric oxide, alumina, and silica on heating clays. At a later stage in the burning, these oxides dissolve in the molten fluxes forming bluish-grey or pale green colours under reducing conditions and pale yellow under oxidising ones. The red discoloration is attributed to free ferric oxide. The discoloration known as *la maladie jaune* or *jaune de cuisson* in hard porcelain is produced by oxidising conditions in the first stages of burning, followed later by reducing ones. Some of the ferric compounds are reduced to ferrous oxide which readily fluxes; at the same time there is an increase in the volume of the gases formed when hydrocarbon gases act as reducing agents, and the ware is thereby blistered. Blue and brown discolorations in bone china are probably due to the formation of ferrous phosphate by reducing gases, as a result of deficiency of alkalis in the body, and by carbon in the bone ash. A brown discoloration may also be caused by the action of chlorides on iron compounds in the body resulting in the formation of the vapour of ferric chloride, which is later converted into red ferric oxide.—A. B. S.

Dressler tunnel oven and its application to the heat treatment of [pottery and] steel. C. Dressler. Trans. Ceram. Soc., 1916–17, 16, 171–188.

IN the Dressler oven the weight of coal used is only 6% of that of clay goods burned at 1000° C., and 8% when burning at 1200° C.; these are the best results achieved industrially in burning clay products. In annealing steel at 850°–1000° C., the metal must be heated without being oxidised. In a modification of the Dressler kiln, this is accomplished by making the structure air-tight, with double, air-tight doors at each end, and filling it with an inert gas. All air required for the combustion of the gas is passed through two tubes fixed longitudinally in the cooling part of the kiln. A small amount of air enters the kiln with each car, but the oxygen in it is not sufficient to do any appreciable harm to the steel. It is claimed that both for clay products and steel, this kiln is economical in fuel and working charges, and that the temperature and atmosphere in it are under complete and easy control. (See also this J., 1916, 539.)—A. B. S.

Firing temperature of a [pottery] body; Possibility of determining the — from the microscopic appearance. J. W. Mellor. Trans. Ceram. Soc., 1916–17, 16, 71–72.

A CRITICISM of Technol. Paper 80 of U.S. Bureau of Standards (this J., 1916, 1220) in which A. Klein claims that (i) it is possible to estimate the burning temperature of porcelain bodies from the way in which sillimanite crystals are developed, and (ii) that the time of burning is less important than the temperature. According to Klein, needles of sillimanite are formed in pottery bodies only to a very slight extent between 1250° and 1275° C. and not at all at lower temperatures, whilst they are formed in abundance only at temperatures above 1300° C. It is now pointed out that Heath and Mellor showed in 1907 (this J., 1909, 474) that sillimanite crystals can develop abundantly in bodies which have never reached 1200° C. The facts indicate that by extending the time of firing similar results can be obtained as at a higher temperature when the time is abbreviated. Moreover, sillimanite crystals develop more freely in certain mixtures than in others, and this fact still further invalidates Klein's claim.—A. B. S.

Temperature measurements in clay works practice. J. W. Cobb. Trans. Ceram. Soc., 1916—17, 16, 118—120.

For temperatures between 50° and 450° C., a mercury thermometer filled with nitrogen under pressure may be used. For 450°—1400° C., a thermo-couple of platinum and platinum-rhodium with recorder is recommended. For temperatures above 1400° C., a Fery radiation pyrometer or an optical pyrometer depending on the brightness of a lamp filament altering with varying resistance should be used. To control heating where the effect of time, temperature, and kiln atmosphere have all to be indicated, Watkin's recorders, Seger cones, Holdcroft thermoscopes, Wedgwood's pyrometer, and Buller's rings are used. Seger cones are usually too small for works use, being fragile, difficult to see when in use, and liable to be unduly affected by accidental heat waves. They are preferably replaced by a larger wedge made of the same material, the top of the wedge being half the size of the bottom.—A. B. S.

Properties of the refractory materials used in the iron and steel industry. Johns. See page 528.

PATENTS.

Glass working machines. British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 105,285, June 15, 1916. (Appl. No. 8453 of 1916.) (See also Eng. Pat. 17,602 of 1913; this J., 1914, 831.)

AN apparatus for drawing glass rod and tubing comprises a receptacle containing molten glass, with a number of gripping devices which travel up and down above the container and draw the molten glass into rod. An adjustable chilling device, arranged near the working level of the glass, comprises a hollow ring, on which a cylindrical shield is supported, on the inner surface of which, and communicating with the ring, a cooling pipe is closely coiled. The gripping devices automatically lower the chilling arrangement as the working level of the glass descends. Cutters are mounted in the path of the grippers and actuated by them to cut the rod into sections, and mechanism is arranged in the path of the grippers to receive these sections when the grippers are released, and a sprocket and chain mechanism, engaged by the grippers, causes one complete to-and-fro movement of the delivery mechanism to deliver sections to a depository.—W. C. H.

[Clay] articles; Process for drying — and apparatus for accomplishing the same. F. A. Second. Assignor to A. P. Paterson and C. H. Peters, St. John, New Brunswick. U.S. Pat. 1,221,383, Apr. 3, 1917. Date of appl., Nov. 17, 1915.

CLAY articles are placed in a closed casing, through which currents of air, having a temperature artificially reduced to about 39.2° F. (4° C.), are circulated until the temperature of the clay is thus artificially reduced. The temperature of the currents of air is then substantially raised, and the circulation of these in the casing continued, whereby moisture is removed from the surface of the clay and from the casing.—W. C. H.

Clay pots or crucibles; Method of making —. H. K. Hitchcock, Tarentum, Pa. U.S. Pat. 1,221,450, Apr. 3, 1917. Date of appl., July 28, 1913.

THE method consists in enclosing a shaped, hollow, moist blank within an air-tight, impervious mould, with its entire outer surface in contact with the mould, and subjecting the hollow inner surface of the blank to a partial vacuum, whereby it is freed from air bubbles, or occluded gas, and excess moisture. The entire inner surface of the blank is then subjected to uniform yielding pressure to compact it equally

throughout, and the blank allowed to remain under pressure until it becomes homogeneous.

—W. C. H.

Grinding and cutting wheels and analogous contrivances; Grinding surfaces of —. W. W. Jenkins, Torquay. Eng. Pat. 105,296, July 14, 1916. (Appl. No. 9932 of 1916.)

THE grinding and abrading surface of grinding wheels is composed of the following ingredients, by weight: 16 parts of fine carborundum, 1 part of coarse carborundum, 1 part of steel "crystals" or "grits" (angular fragments of a specially hard steel), all intimately mixed and bound together with 6 parts of shellac or the like.—W. C. H.

IX.—BUILDING MATERIALS.

Magnesite bricks; Spalling of —. J. W. Mellor. Trans. Ceram. Soc., 1916—17, 16, 85—100.

FITZGERALD (this J., 1912, 337) has stated that the spalling of magnesite bricks is due to their great shrinkage (accompanied by a corresponding increase in the specific gravity) when heated. Lightly calcined or α -magnesia has a sp. gr. of 3.2 or 3.3, but the crystalline or fully shrunk β -magnesia has a sp. gr. of 3.65; that of the natural mineral (periclase) is 3.5—3.75. Some powdered commercial magnesite bricks had a sp. gr. of 3.44, and assuming the maximum to be 3.7, such bricks correspond to a mixture of 40.5% of the dense magnesia and 59.5% of the unconverted form, and may contract 7%. Bricks with a sufficiently high sp. gr. do not spall, as the change in volume on further heating is too small to set up serious strains. The speed of conversion from α - into β -magnesia at 1300° C. is relatively slow, but is more rapid at higher temperatures, though different types of magnesite each have their specific rate of conversion. To prevent spalling, the material must not merely be heated to a suitable temperature; it must be maintained at that temperature until a sufficient amount of conversion has occurred. Spalling is attributed to (i) shrinkage caused by conversion of α - into β -magnesia, (ii) shrinkage caused by the closing of the pores in highly porous bricks. Bricks which are not sufficiently porous will probably crack or "dunt" with abrupt changes in temperature. The remedies for spalling are to heat the bricks sufficiently long to secure sufficient β -magnesia being formed, and to keep the porosity of the bricks reasonably low.—A. B. S.

Zirconia; Use of — as a refractory material. J. A. Audley. Trans. Ceram. Soc., 1916—17, 16, 121—133.

A BRIEF outline of the occurrence, properties, and uses of zirconia, is given. Baddeleyite (82—94% ZrO_2) from Brazil is the chief source of zirconia, but zircon ($ZrSiO_4$) from monazite sand, etc., is sometimes used. Zirconia has a hardness of 6.5, sp. gr. 4.4—6, grey colour, light yellow streak, very low electrical and thermal conductivity, and high melting point (nearly 2000° C.). It can be melted in an electric furnace (360 amps., 70 volts). It is insoluble in acids, except hydrofluoric acid, and resists fused cyanides and alkalis, but is easily attacked by fusion with potassium bisulphate and fluorides. Bricks made of crude baddeleyite bonded with clay will resist a temperature of 1650° C., if previously burned to a higher temperature; otherwise they crack. Superior bricks are made by extracting the iron oxide from the crude ore with dilute sulphuric or hydrochloric acid. The use of zirconia for muffles, retorts, and tubes was patented by Pyhal in 1904 and for crucibles by the Heraeus Co. in 1906. More recently it has been used for lamp filaments and for lining electric furnaces. Several more recent German patents are mentioned, as is also the work of Podszus (this J., 1917, 217). Ruff and Lauschie

(this J., 1917, 85) found that marketed zirconia articles usually contain so much clay or silica that they cannot be used owing to softening at 1800° C. or to their porosity being above 15%. Beryllia, alumina, thoria, and yttria are suitable bonds if not more than 1% is used; silica and magnesia are less satisfactory on account of their volatilisation at 2000° C. Crucibles made of calcined zirconia with one of the foregoing bonds acquire a crystalline structure at 2200° C., but keep their shape at 2400° C. unless the heating is irregular. They are more compact and harder than clay crucibles, but zirconium carbides form and they cannot be used more than three times. Crucibles made of raw zirconia blistered below 2000° C. and were excessively porous. Well-made crucibles lose weight by reduction of zirconia to lower oxides and formation of carbides, by volatilisation of added oxides, and sublimation of the zirconia. They fall to pieces on prolonged heating at 2200° C. owing to change of texture and formation of oxidation and reduction products; the use of 6% of alumina prevents this.—A. B. S.

Destruction of concrete by gas liquor. Ott. See IIA.

Acid and basic furnace linings [for the iron and steel industry]. Foster. See VIII.

PATENTS.

Cement or composition; Bituminous — and method of making the same. R. Illema, Glasgow. Eng. Pat. 105,202, Oct. 12, 1916. (Appl. No. 14,484 of 1916.)

ABOUT 3 parts by weight of clay is mixed with 3 parts of water and added to 5 parts of bitumen or pitch which has been rendered fluid by heat. The mixture is thoroughly stirred until emulsified, the heat applied being kept low enough to avoid evaporating the moisture from the mixture. The finished moist and plastic composition can be rendered fluid, without the aid of heat, merely by the addition of water.—W. C. H.

Cement [; Refractory —]. F. W. Sperr, jun., and R. J. Montgomery. Assignors to H. Koppers Co., Pittsburgh, Pa. U.S. Pat. 1,221,618, Apr. 3, 1917. Date of appl., Mar. 7, 1916.

THE cement mixture is composed of approximately 25% of fireclay, 35% of silica, 35% of silica bats, and 5% of felspar.—W. C. H.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Chromium; Determination of — in ferro-chromium, steel, and slags by the permanganate method. P. Koch. Chem.-Zeit., 1917, 41, 61.

FROM 0.2 to 0.3 gm. of the finely divided material is weighed into a porcelain crucible, 1 gm. of sodium peroxide added, and the mixture fused by heating carefully with a small flame, or on a sand bath, so as to avoid too high a temperature. When cold, the product is extracted in a beaker with a litre of boiling water, which is then boiled for a further half hour to decompose the hydrogen peroxide. The solution is acidified with sulphuric acid to dissolve the ferric oxide and a measured excess of ferrous sulphate solution is added, when the yellow colour of the chromic acid changes to that of green chromium sulphate, and the excess of ferrous sulphate is titrated with permanganate solution. The end point, which is indicated by the disappearance of the green colour due to ferrous salt, is best observed by diluting the solution with water to 2 litres. The red colour of the permanganate is masked by the complementary colour of the chromium salt. The titration of all chromium solutions requires to be conducted rapidly. The analysis of chromium alloys by

liberation of iodine by chromic acid and titration with thiosulphate gives an erroneously high value for the chromium through the presence of other compounds which liberate iodine. If the fusion with sodium peroxide is made in a nickel crucible, the solution must be freed from particles of nickel and nickel oxide by filtration before acidifying. An alternative method, applicable to the estimation of chromium in steels, consists in dissolving 1 gm. of the metal in dilute sulphuric acid, oxidising with saturated potassium permanganate solution until the red colour of the latter persists on continued boiling, adding 10 to 20 c.c. of manganese sulphate solution, filtering from the separated manganese dioxide, and then adding standard ferrous sulphate solution and titrating with potassium permanganate. With slags containing manganese, 3 to 5 grms. is well mixed with 20 to 40 grms. of sodium peroxide and heated in a crucible of nickel, iron, or copper until disintegration of the slag is complete, the product is extracted with hot water, boiled, and the residue containing manganese dioxide and the oxides of silicon and iron is filtered off. The small quantity of manganese which is held in solution as manganate and permanganate is decomposed as before by boiling the acidified solution with a few c.c. of manganese sulphide, and the solution is filtered, and the chromium estimated by adding ferrous sulphate and titrating back with potassium permanganate or N/10 potassium chromate or bichromate.—J. N. P.

Galvanised iron; Stripping and analysis of —. G. W. Heise and A. Clemente. Philippine J. Sci., 1916, 11, 135—146.

THE separation of zinc from galvanised iron for the purpose of analysis and recovery of the metal, was examined by taking samples cut from a sheet which analysis had shown to be approximately uniform in composition, and immersing in a reagent for definite intervals or until no further loss in weight occurred. With acetic acid, cadmium nitrate, ammoniacal copper sulphate, cobalt acetate, and chromium nitrate, the action was very slow, whilst with lead acetate, either alone or in presence of acetic acid or sodium hydroxide, with cobalt acetate or nitrate in presence of ammonia, with sodium bisulphate (concentrated), and with boiling sodium peroxide, the reaction was rapid and gave a quantitative separation of the zinc from the iron. Good results were also obtained with 2% sulphuric acid solution containing a little arsenic trioxide, which has an inhibitive effect on the solution of the iron, with phosphoric acid (25% by vol.), and with hydrochloric acid (sp. gr. 1.19). In these cases removal of the zinc is characterised by an effervescence which ceases entirely when the iron of the base is reached. Phosphoric acid reacts slowly, but the stripped iron can be left immersed for a long time without appreciable loss. With hydrochloric acid the loss in weight was less than 0.002 gm. after 30 minutes' additional immersion. The experiments with metallic salts gave an indication of the changes in the potential of zinc and iron which occur in different liquids and, together with the character of the metallic deposit, which in some cases is crystalline and adherent, and in others loose and spongy, determine the progress of the solution. The separation of zinc by using the sample as anode in alkaline or acid solutions is sufficiently complete and clean-cut to serve as a rapid and accurate method of analysis. The solutions used were saturated potassium chlorate or nitrate, 30% sodium nitrate, 20% chromium nitrate, or 20% potassium or sodium hydroxide. With a voltage of 3 and a current density of 15—25 amps. per sq. dm. the zinc was completely removed in a few minutes. Except with an electrolyte of chromium nitrate,

there was no noticeable action on the iron base on continued passage of the current. Though the presence of iron could always be shown in the solution after the zinc had been removed, the constancy of the results recorded for the thickness of the coating, and the constancy of the amount of iron removed in the different trials, indicated that the metal was derived from the layer of zinc-iron alloy formed when iron is galvanised by the hot process. The separation of zinc from galvanised iron was also brought about satisfactorily by arranging a plate 3.8 cm. square as cathode in a sulphuric acid solution (20% by vol.) and passing a current of 0.75 to 1.7 amp. Iron from the surface alloy was dissolved but no metal from the iron base, and the separation was complete in a few minutes.—J. N. P.

Galvanised iron; Testing of — J. C. Witt. Philippine J. Sci., 1916, 11, 147—165.

AN examination was made of the different methods which have been introduced for the estimation of zinc on galvanised iron. On account of the non-uniformity of the coating, which was found to lead to variations amounting to 12.3% in the thickness of the coating on different parts of a plate, it was found desirable that estimations should be made with samples at least 15 cm. \times 15 cm. square. The use of sodium hydroxide as a solvent for the zinc is unsatisfactory. The method in most general use measures the time necessary for removal of the zinc by immersion in neutral copper sulphate solution, but has the disadvantage that the zinc does not dissolve at a constant rate since the coating is not homogeneous and the zinc-iron alloys in the lower layers are less electro-positive than the pure zinc. A misleading result is thus given by the fact that alloyed iron diminishes the rate of solution of the zinc in the copper sulphate, but increases its rate of corrosion when exposed to the atmosphere. The zinc layer can be removed by means of neutral lead acetate, but in order to remove the alloy layers, it is necessary to use a large excess of the lead salt. More uniform and complete removal of the zinc is obtained by hydrochloric acid solution, preferably of a concentration of 19.5% acid (sp. gr. 1.098 at 15° C.). The temperature should not exceed 45° C. during the reaction. The plate is immersed until effervescence ceases, then washed, dried, and weighed. Comparative estimations showed that the amount of iron dissolved by the hydrochloric acid solution was constant in different determinations and slightly greater than that removed by lead acetate solution, on account of incomplete solution of the zinc-iron alloys with the latter solvent. On treating galvanised sheets with a solution of hydrochloric acid (10.5%) it was found that during the first minute the amount of iron which passed into solution was 0.65% of the total metal dissolved and could be accounted for by the initial contamination of the molten zinc used for galvanising. After 3 mins. 91.2% of the total zinc and 24.2% of the total alloyed iron was dissolved. During the next 3 mins. 8.22% more of the zinc and 65.38% more of the iron dissolved. During the following 4 mins. only 0.53% of the zinc and 10.42% of the iron was dissolved. The large increase in the ratio of iron to zinc dissolved in the later stages would indicate that in addition to alloys like FeZn₃ and FeZn₇, there may be a series high in iron and low in zinc such as Fe₂Zn and Fe₁₁Zn. During the dissolving of the outer coating of almost pure zinc, the curve showing the relation of the rate of solution with time is nearly a straight line which bends very sharply when the layer of alloy is reached. An estimation of the duration of this first period and the amount of iron dissolved gives a measure of the purity of the outside coating of zinc and the thickness of the layer, which are the two factors determining the capacity of the sheet to withstand corrosion.—J. N. P.

Galvanised-iron roofing in the Philippines. A. S. Argüelles. Philip. J. Sci., 1916, 11, 177—181.

THE greater durability of old in comparison to modern galvanised iron sheets was found to be due to the increased thickness of the zinc coating with the former. A minimum of 2.5 oz. of zinc per square foot is necessary for satisfactory service in the Philippines. The amount of lead found in the zinc, which was in all cases below 1%, was approximately the same in old and modern sheets, and probably insufficient to affect adversely the durability. Small amounts of chlorides derived from the fluxes used in the hot bath were in all cases found in the metal. The iron dissolved by 3% sulphuric acid, assumed to represent the iron alloyed with zinc, bore approximately the same ratio to the total zinc in both old and modern sheets. The advanced corrosion of sheets newly arrived or after being kept in storage in the Philippines, is attributed to the influence of moisture either through actual contact with water or through the presence of damp air.—J. N. P.

Tin plate; Detinning and analysis of — G. W. Heise and A. Clemente. Philipp. J. Sci., 1916, 11, 191—199.

AN investigation was made of the different methods of analysing tinned iron plates. By dissolving the tin in hydrochloric acid and titrating with iodine, a mean value of 0.089 oz. of tin per sq. foot of surface was obtained. By the method of repeated immersion in boiling sodium peroxide solution, followed by acidifying with sulphuric acid, a higher average value of 0.105 oz. per sq. foot was obtained, the difference representing the amount of iron removed with the tin. That this iron was part of the alloy and not due to attack on the base was shown by the fact that there was no further loss in weight on subsequent treatment with sodium peroxide. The most rapid and accurate method of determination was found to consist in arranging a section of tin plate, 5 cm. \times 5 cm. square, as anode in a 30% sodium nitrate solution and electrolysis with a current of 0.7 amp. The tin is completely removed within 10 mins., and the iron of the alloy is left in the bath and can be readily determined by recovering as ferric hydroxide, while the iron of the base is left unattacked. An average value of 0.105 oz. tin per sq. foot was obtained by this method. Accurate results are also obtained by the use of lead acetate in presence of sodium or potassium hydroxide, when the tin is rapidly dissolved and lead deposited in a spongy condition. After immersion for 5 mins., the average value found was 0.098 oz. tin per sq. foot, and after 3 days, 0.105 oz. Lead nitrate in neutral or acetic acid solution has no action on tin plate. Chromium, aluminium, and copper salts in presence of alkali have a similar solvent action on tin, though the solution is slower and less complete than with sodium plumbite. Concentrated nitric acid will remove tin without attacking the iron base. Estimates of the iron present as alloy in the tin coatings in the samples analysed gave a value of about 15% of the weight of tin.—J. N. P.

Zinc extraction; Physical-chemical conditions of metallurgical — Bodenstein. Deutsche Bunsen-Ges., Dec., 1916. Chem.-Zeit., 1917, 41, 9.

DETERMINATIONS of the equilibrium pressure attained in the decomposition of zinc oxide by carbon (both in the form of ignited wood charcoal and of Acheson graphite) at temperatures ranging from 596° to 795° C. showed that equilibrium was established very slowly, and the main equilibrium is complicated by the presence of carbon dioxide and of zinc as a liquid phase. Even at atmospheric pressure the reaction may be made to yield zinc in the liquid state, but the reaction velocity is too small to admit of technical application.—F. SODN.

Antimony; Methods of recovering—from its ores by volatilisation processes. J. A. DeCew. Canadian Soc. Civil Eng., Mar. 15, 1917. Met. and Chem. Eng., 1917, 16, 441.

IN the manufacture of antimony trioxide from sulphide ores by the combustion process, the gases passing from the zone of combustion to the condensing chamber slowly deposit the antimony oxide in the form of white fume. The problem of obtaining complete combustion of the ore presents many difficulties, since satisfactory conditions exist only in a limited part of the furnace and difficulty may arise through fusion or through distillation of unoxidised ore. In practice a large excess of air, about five times the theoretical quantity, has to be employed. This is when treating an ore averaging 10% of metal and when 4% of coke is mixed with the ore; the coke however, could be more advantageously applied to heating the air supply. With a stack furnace relatively deep and not too large in diameter, good results may be obtained; the area should increase with the depth so that in case of fusion the ore would not be held up by the side walls. The condensation of the white fume is a difficult operation; antimony trioxide boils at 1550° C. but is molten at a red heat, so that any oxide which separates above 750° C. appears as liquid particles, solidifying to a dense mass more difficult to reduce to metal than the snow-like deposits formed at lower temperatures. The particles of fume condensing below the fusion point are so minute that they exhibit Brownian movement, exert osmotic pressure, resist the effect of gravity, and possess properties analogous to those of colloidal particles in an aqueous medium. Each particle is surrounded by a layer of air or gas and shows electro-repulsion due to similar electric charges, so that when the oxide finally settles the density of the powder is extremely low. The volume of air being very large, a very large condensing area is necessary to reduce the velocity of the gases sufficiently to allow the oxide to settle. Every effort must be made to cool the gases as rapidly as possible, but the use of water sprays or scrubbers is of little value, as the particles tend to repel water and are wetted only with difficulty; moreover antimony trioxide which has been wetted and dried has a lower market value than the dry condensed fume. In view of the conditions above stated, there is a demand for some system of condensation and settling other than by gravity, and attention is drawn to the possibility of separating the minute solid particles from the moving gases by the application of centrifugal force, which has been employed at an intensity of 40,000 times that of gravity for the separation of colloidal solutions (see this J., 1917, 375). An apparatus is illustrated which has been designed for the application of the Cottrell system of high voltage electric discharge to the separation of the trioxide fume, and there is every reason to expect an improved recovery and a more densely packed product by this treatment. If arsenic be present in the ore, a portion of the arsenious oxide enters into combination with the antimony oxide to form an antimonate and cannot be extracted by washing with caustic alkali. The antimonate is decomposed by heating to a high temperature and a process of fractional distillation of the oxides might successfully be employed. A furnace for the reduction of antimony oxide to metal is illustrated. The question of the effect of the presence of arsenic in the metal is discussed; the two elements are so closely allied that for many requirements they serve the same purpose. Alloys of antimony and arsenic are more brittle than pure antimony but when used for hardening other metals they are equivalent. Antimony containing 2–3% of arsenic cannot be purified by distillation of the latter in absence of air, because the pressure

of diffusion is just about sufficient to counteract the pressure of the arsenic vapour. When fused in presence of air the antimony is burned off at about the same rate as the arsenic. One of the chief uses for antimony trioxide is in the manufacture of enamel ware; the tetroxide is useless for this, owing to its infusibility; the commercial product is tested for its solubility in acids as a measure of its fusibility and freedom from tetroxide. The presence of small quantities of arsenious oxide would appear to be non-detrimental and increases the fusibility and ease of working.—J. F. B.

Babbitt metal; Analysis of— J. C. Witt. Philippine J. Sci., 1916, 11, 169–175.

IN the analysis of anti-friction alloys containing Pb 50 to 90%, Sb 10–15%, Sn 0–5%, and Cu 0–1%, the estimation of antimony and tin is made by heating in an Erlenmeyer flask 0.2–1 gm. of the alloy with strong sulphuric acid until thoroughly decomposed. After cooling, water and hydrochloric acid are added and the solution is boiled to expel all the sulphur dioxide. Antimony is then estimated by titrating rapidly with standardised potassium permanganate. Tin is estimated by adding 1 gm. of steel turnings to the hydrochloric acid solution, and, after excluding air by maintaining an atmosphere of carbon dioxide, the solution is boiled until all the steel is dissolved, when, after quickly cooling, while still excluding air, starch solution is added and the solution titrated with N/10 iodine. Lead is estimated by dissolving the alloy in nitric acid, adding excess of sulphuric acid, allowing the lead sulphate precipitate to settle, filtering, and washing with sulphuric acid solution, dissolving in hot ammonium acetate solution, and titrating with standardised ammonium molybdate, using tannic acid as an outside indicator. The solution must be almost boiling at the beginning of the titration to ensure complete precipitation of the lead. Copper, which is present in these alloys only in small amounts, is estimated colorimetrically with ammonia, using as a standard of comparison, a babbitt alloy of known copper content. Iron may be determined as ferric oxide in the filtrate from the lead sulphate after removing any remaining lead with hydrogen sulphide, and zinc may be determined in the filtrate from the iron.—J. N. P.

Magnesium; Action of—on aqueous solutions. F. H. Getman. J. Amer. Chem. Soc., 1917, 39, 596–601.

MAGNESIUM, in the form of wire containing 99.6% Mg, or powder as obtained by distillation *in vacuo*, was added to a N/10 solution of potassium chloride which formed the electrolyte of a cell containing, as one pole, a standard calomel electrode, and as the second electrode, platinum surrounded by an atmosphere of hydrogen. The E.M.F. of this element is determined by the concentration of hydrogen ions, and with carefully purified materials was initially 0.33 volt. On the introduction of magnesium, the formation of hydroxyl ions following from the reaction, $\text{Mg} + 2\text{H}_2\text{O} \rightarrow \text{Mg}(\text{OH})_2 + \text{H}_2$, caused a proportionate decrease of the hydrogen ions, and the resulting change of potential gave a measure of the extent of the reaction and enabled its progress with time to be observed. A comparison of magnesium wire with the purer distilled metal showed a larger initial reduction of the hydrogen ions with the latter in accordance with the greater surface exposed, though with time the E.M.F. in the two cases tended to approach the same limiting value, indicating that the small amount of impurity present in the magnesium wire did not exert any appreciable influence on the reaction between the metal and the saline solution. A

comparison of the curves showing the change of the E.M.F. with time was made with the volume of hydrogen evolved on exposure of magnesium to a number of different salt solutions for measured intervals. With the exception of ammonium chloride, which gave an abnormally large evolution of hydrogen and hydrogen ion concentration through the slight hydrolysis of the salt in aqueous solution, the salts of univalent and divalent metals gave curves for the E.M.F. of similar form but, in each case, with differences in both the initial E.M.F., indicating the concentration of the hydrogen ions before adding the magnesium, and in the limiting values reached after an interval of about 80 minutes. With an electrolyte of ammonium chloride, variable E.M.F.'s were first obtained through liberation of some ammonia by the current of hydrogen, leaving the solution acid. It was accordingly found necessary first to pass the hydrogen through wash-bottles containing a solution of this salt so as to establish equilibrium with the displaced ammonia before admitting to the electrode. With an acid electrolyte, or a salt like aluminium chloride which yields free acid, complete neutralisation by the magnesium was attained after a few hours, and thereafter the curve followed the normal course. With alkaline electrolytes, including those in which alkali was formed by hydrolysis of salts of weak acids, such as sodium carbonate and tetraborate, a marked depression of the hydrogen ion concentration was obtained, but no change occurred with time nor with the introduction of magnesium. With non-electrolytes such as sucrose, mannitol, and urea, the concentration of the hydrogen ions was depressed by magnesium to nearly the same extent as with solutions of many of the neutral salts, yet the volume of hydrogen evolved was hardly greater than when magnesium is immersed in pure water alone, thus indicating that the accelerating influence of a dissolved salt on the reaction between magnesium and water is to be ascribed to a catalytic influence of the ions of the salt rather than of the non-ionised molecules. —J. N. P.

Ferrophosphorus: Process of making — J. J. Gray, jun., Rockdale, Tenn. U.S. Pat. 1,220,416. Mar. 27, 1917. Date of appl. Dec. 28, 1916.

A CHARGE of iron ore, phosphate rock, fluxing materials, and carbon is heated in a blast furnace, the lower part of which is maintained at above 2000° F. (about 1090° C.), and the upper zone at not above 700° F. (390° C.). At the higher temperature the phosphate is reduced by the free carbon, and the liberated phosphorus reduces the iron ore as it descends through the furnace, and combines with the iron. To prevent the occurrence of a "dirty hearth," the furnace is charged at intervals with ferruginous material, phosphate rock, silica, and an excess of carbon. When this is smelted, a charge of iron ore, basic material, and carbon is immediately added. —E. H. T.

Ferromanganese: Manufacture of — in the blast furnace, using manganese ores rich in oxygen. F. Lange, Essen-Bredney. Ger. Pat. 295,549. Nov. 27, 1915.

THE finely powdered ore, which may be mixed with finely powdered coal and limestone, is blown into the furnace through the tuyères. Wear and tear due to excessive heat in the upper part of the furnace is thereby prevented, and the high oxygen content of the ore is utilised in the fusion zone, whilst the proportion of carbon dioxide in the exit gases is reduced. —F. SODN.

Crucible furnaces. F. S. Wigley, Birmingham. Eng. Pat. 105,116. May 25 and Dec. 13, 1916. (Appl. Nos. 7434 and 17,882 of 1916.)

A CRUCIBLE furnace has a firebar frame so fixed into the brickwork as to allow an up-draught of air around it, and also an auxiliary frame, which supports the firebrick lining and forms lateral air inlet openings above the firebars. The upper surface of the firebar frame is narrow and has rounded edges to prevent coke from resting immediately underneath the auxiliary frame. The latter is cast with supporting blocks projecting downwards, while the firebar frame is cast with similar blocks on its upper surface, to maintain the auxiliary frame at the proper height above the firebar frame. —W. R. S.

Furnace-hearth: Method of making — J. H. Gray, New York. U.S. Pat. 1,220,839. Mar. 27, 1917. Date of appl. Jan. 23, 1914.

A FURNACE hearth is made of magnesite or the like by heating the material *in situ* in the furnace to a temperature at which it becomes electrically conducting, and then forming an electric arc from an electrode to the material so that it is heated to a pasty condition, when it can be moulded to the desired shape. —W. F. F.

[Ore roasting] furnace. W. W. Whitton, Oakland, Cal. U.S. Pat. 1,222,251. Apr. 10, 1917. Date of appl. June 21, 1916.

THE heating chamber of the furnace contains vertical retort tubes, each traversed by a central perforated pipe. The upper ends of the retorts are held in a frame with rectangular openings, by means of plates forming a closure around each retort. An ore bin surrounds the upper open ends of the retorts, to permit a continuous delivery of ore. A receiving plate is mounted a certain distance below the lower open ends of the retorts, where the roasted ore is removed without disturbing the perforated pipes. The latter are connected to a condenser below the receiving plate. —W. R. S.

Brass borings, turnings, and the like; Separation and extraction of dust and iron from—W. Sowden, Leeds, Eng. Pat. 105,171, July 21, 1916. (Appl. No. 10,275 of 1916.)

THE apparatus comprises a hopper connected by a rotating worm conveyor with a separating chamber in which an upward air blast separates the dust from the heavier material; the chamber contains reciprocating electro-magnets, each of which when in its inner position attracts the particles of iron, and when in its outer position is demagnetised so that the iron drops into a discharge shoot. The magnets may be disposed in opposite pairs, the reciprocating movement of which is controlled from a main shaft which also drives the feed worm shaft.—W. R. S.

Speller; Condenser for redistilling—J. G. Granberg, Beckemeyer, Ill. U.S. Pat. 1,221,015, Apr. 3, 1917. Date of appl., Dec. 8, 1916.

THE end of the earthenware receiver, which makes close contact with the retort, is provided with a bridge which closes the lower part of the opening. To prevent leakage at the junction of the retort and receiver, the end of the condenser is flanged inwards. The closed end of the receiver is provided with an opening, fitted with an earthenware plug, for the purpose of withdrawing the charge.—J. N. P.

Zinc; Chemical primer for—J. H. Gravell, Philadelphia, Pa. U.S. Pat. 1,221,016, Apr. 3, 1917. Date of appl., July 22, 1916.

A MIXTURE used for producing a coating on zinc consists of nitric acid and phosphoric acid dissolved in a solvent, e.g., water, which itself has no action on the metal.—J. N. P.

Metals; Production of—of improved quality [in a combined blast- and electric-furnace]—H. M. Chance, Philadelphia, Pa. U.S. Pat. 1,221,139, Apr. 3, 1917. Date of appl., June 12, 1916.

THE ore is mixed with the necessary fuel and fluxes and charged into a blast furnace where a preliminary smelting is effected by means of an air blast. After separation of the metal and slag has occurred, further heating is effected by the passage of an electric current, which is admitted by pole pieces connected respectively with the slag and with the molten metal.—J. N. P.

Metal-plating [galvanising]; Method of—E. L. Watrous, Des Moines, Iowa, Assignor to E. L. Watrous Galvanizing Co. U.S. Pat. 1,221,397, Apr. 3, 1917. Date of appl., May 3, 1909. Renewed Feb. 26, 1917.

SMALL iron articles are placed loosely in a receptacle having perforated sides, which is then immersed in a bath of molten zinc and allowed to remain until the zinc alloys with the surface metal. The receptacle is then transferred to a rotary support and subjected to centrifugal action while maintaining a uniform temperature, so as to throw off the excess of zinc and produce a smooth, uniform coating.—J. N. P.

Metals; Cleaning—and preventing them from corroding—J. H. Gravell, Philadelphia, Pa. U.S. Pat. (A) 1,221,141 and (B) 1,221,142, Apr. 3, 1917. Dates of appl., Nov. 15, and Dec. 26, 1916.

STEEL is cleaned and prevented from rusting by treating it with an aqueous solution of calcium phosphate and (A) sulphuric acid or (B) sodium bisulphate, so as to form calcium hydrogen phosphate; manganese dioxide may also be added to the solution.—J. N. P.

Metal articles; Process for pickling—A. F. Hoffman and W. M. Parkin, Pittsburgh, Pa. U.S. Pat. 1,221,735, Apr. 3, 1917. Date of appl., Dec. 5, 1916.

THE articles are immersed in an acid bath to which is added a small quantity of waste sulphite liquor, which has been freed from sulphites by precipitating with a basic calcium compound and filtering off the precipitate.—W. R. S.

Alloy—H. S. Cooper, Assignor to The Cooper Co., Cleveland, Ohio. U.S. Pat. 1,221,769, Apr. 3, 1917. Date of appl., Oct. 30, 1916.

A SELF-HARDENING alloy for cutting tools consists mainly of nickel, or nickel and cobalt, together with from 2 to 10% zirconium, and with a "small amount" (not more than 35%) of one or more of the metals of the chromium group.—J. N. P.

Alloys; Process of producing—I. Ladoff, Wilkinsburg, Pa., Assignor to W. D. Edmonds, Boonville, N.Y. U.S. Pat. 1,221,873, Apr. 10, 1917. Date of appl., Oct. 12, 1915.

THE oxides of the constituent metals of the desired alloy are mixed with an oxygen compound, the reduction temperature of which is lower than that of one of the oxides, and the charge is then subjected in a reducing atmosphere to a temperature below the melting points of the metals, but sufficiently high and maintained sufficiently long to bring about the reduction of the oxides. An oxygen compound of arsenic is specified as suitable for carrying out the reaction.—J. B. C. K.

Alloys; Method of making—I. Ladoff, Wilkinsburg, Pa., Assignor to W. D. Edmonds, Boonville, N.Y. U.S. Pat. 1,221,874, Apr. 10, 1917. Date of appl., Feb. 25, 1916.

OXIDES of tungsten, chromium, and vanadium are mixed with a ferro-metal or its oxide in the proportions necessary to produce a ferro-alloy containing not less than 50% of alloying metals, and the mass is then heated and reduced to the metallic state at a temperature below that of the melting points of the respective metals. The reduced mass is then melted in a molten bath of another ferro-metal, to obtain a high-speed tool-steel.—J. B. C. K.

Aluminium-soldering compound—C. A. Stewart, Carson City, Nev. U.S. Pat. 1,222,158, Apr. 10, 1917. Date of appl., May 13, 1916.

THE solder contains tin 69.07, lead 28.77, zinc 1.41, and silver 0.72%.—W. R. S.

Sintering fine oxide ore and metallurgical products; Process for—H. Bittmann, Frankfurt, Germany, Assignor to Dwight and Lloyd Sintering Co., New York. U.S. Pat. 1,221,962, Apr. 10, 1917. Date of appl., July 16, 1914.

AIR is passed in an upward direction through a layer of ignited carbonaceous fuel to bring it to a state of active combustion, and a layer of the ore or other material under treatment is then deposited on the fuel layer, the passage of air being continued. By the action of the heat and the carbon oxides generated by the combustion of the fuel, the oxide particles in the ore layer are caused to agglomerate, thin, coherent, sintered masses, suitable for blast-furnace treatment, being produced.

Ores; Process of desulphurising—H. F. Wierum, Upper Montclair, N.J., Assignor to The Sulphur Syndicate, Ltd., London. U.S. Pat. 1,222,252, Apr. 10, 1917. Date of appl., Sept. 15, 1913. Renewed Sept. 15, 1916.

PYRRHOTITE or other sulphide ores or mattes are powdered and mixed with carbonaceous fuel; the mixture is heated, while being agitated, to 700°–900° C. by a direct flame, in presence of sufficient steam to decompose any carbon oxy-

sulphide formed, the sulphur distilling in the free state. The treatment is continued until all the fuel has burned away.—W. R. S.

Briquetting metal-cuttings; Method of and means for—Campbells and Hunter, Ltd., and C. Korte, Leeds. Eng. Pat. 105,245, Jan. 3, 1916. (Appl. No. 1 of 1916.)

Furnaces; Tilting—S. W. Price, London. Eng. Pat. 105,381, Apr. 7, 1916. (Appl. No. 5139 of 1916.)

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Colophony; Ammonium soaps of—L. Paul, Seifenfabr., 1916, 36, 545—546, 567—569. J. Chem. Soc., 1917, 112, i., 214—216. (See this J., 1915, 1062; 1916, 478.)

AN alcoholic solution of colophony solidifies to a stiff jelly when poured into dilute ammonia. Larger quantities of the jelly are conveniently prepared by grinding γ -pinic acid with distilled water and treatment with ammonia in excess. The ammonium soap thus prepared greatly resembles the γ -sodium resin soap. Both form additive compounds with petroleum (compare this J., 1915, 1153). Aqueous solutions of both resin soaps can be boiled without decomposition; on the other hand, decomposition is always observed with the γ -ammonium soap if this has been prepared with relatively little ammonia. If a concentrated alcoholic solution of colophony is poured into very dilute aqueous ammonia, a solution is obtained which deposits some resinous matter on boiling, and forms a milky emulsion, from which unchanged γ -pinic acid, m. pt. 74°—76° C., is obtained by filtration or by treatment with hydrochloric acid. α -Pinic acid, m. pt. 101°—103° C., is formed by addition of hydrochloric acid to the filtrate. Similar precipitates, m. pt. about 98° C., are obtained when preserved colophony powder ("KS") is treated with ammonia. γ -Pinic acid ("KS"-acid) does not invariably melt at 76° C., but often between 85° and 88° C. A resin acid, m. pt. 85°—87° C., is obtained from the calcium salts contained in the filtrate from the precipitation of γ -sodium resin soap by water containing calcium as well as by decomposition of the non-gelatinised ammonium soap. Further, γ -pinic acid, m. pt. 85°—87° C., is obtained from γ -sodium resin soap by means of ether. The higher m. pt. is attributed to the entrance of calcium into the resin and its non-removal by hydrochloric acid. A transparent piece of colophony yields the sodium resin soap with sodium hydroxide, from which γ -pinic acid, m. pt. 75°—76.5° C., can be separated. If the latter is washed with much conductivity water the m. pt. rises to 85°—87° C. Further, a substance, m. pt. 85°—87° C., was obtained in the investigation of a two and a-half years old specimen of γ -pinic acid, which, in contrast to the former substance, was soluble in water. γ -Pinic acid gradually becomes transformed into α -pinic acid. Similarly, in the course of time, α -pinic acid is converted into β -pinic acid, m. pt. 122°—123° C. The autoxidation of colophony is to be compared with the conversion of α -pinic acid into the β -compound. This is shown not only by the crumbling of colophony to powder (consisting chiefly of β -pinic acid), but also by the fact that α -pinic acid, m. pt. 100°—105° C., passes within a short period into the β -compound. The α - and β -acids can be separated by the ammonia method, since the ammonium salt of the α -acid is readily decomposed, whilst the β compound shows little or no instability. γ -Pinic acid, the m. pt. of which had risen from 74°—77° C. to above 100° C. during two and a-half years, was stirred with water and ammonia, when a separation of γ -ammonium resin soap was not observed. Before being boiled, the solution deposited considerable quantities (18 grms. from 35 grms.) of a plastic mass (Kpl), m. pt. 95°—98° C. The filtrate was treated with hydrochloric acid and the precipitate dissolved in conductivity water. Hydrochloric acid precipitated β -pinic acid, m. pt. about 120° C., from the extracts, so that the substance directly precipitated with ammonia is to be regarded as fairly pure β -pinic acid. Colophony is similarly decomposed with separation of "Kpl." In the "Kpl.-substance" a resinous matter intermediate between α - and γ -pinic acids is present (in addition to α -acid),

which possibly represents the first product of transformation. Colophony which had been treated with nitric acid showed the same decomposition when treated with ammonia and boiled: the filtrate also contained β -pinic acid, the latter being characterised by its solubility in water and the formation of fluorescent, resin-like solutions. Colophony is changed in a few hours by nitric acid in the same manner as by exposure to air for years. This transformation of colophony is attributed to the action of colloidal contained water. On the other hand, colophony can decompose owing to loss of water. Whereas sylvic acid is formed by the action of cold alcohol, hot alcohol causes the formation of γ -abietic acid. Resinous substances may be classified into those soluble in petroleum (γ -pinic acid, sylvic acid, γ -abietic acid) and those insoluble in petroleum (Kpl. α - and β -pinic acids), but the classification is not final.

Action of ozone on organic compounds [resins]. Harries and others. See XX.

PATENTS.

Agitating the liquid contents of tanks for coating [with paint] or treating by dipping; Means for —, C. G. Heywood, Chislehurst, Kent, and F. G. Kidd, London. Eng. Pat. 105,138, May 6, 1916. (Appl. No. 6552 of 1916.)

IN a tank for coating or treating articles by dipping, the liquid mixture, e.g., paint, is kept uniformly mixed by the movement of a submerged horizontal foraminous or perforated screen. The screen may be raised and lowered synchronously with the articles dipped, and this movement may be combined with alternating horizontal movements. Alternatively mixing may be effected by angular oscillation of the screen. The movements may be produced by suspending the screen from rotating eccentrics, or the screen may be fixed and the tank movable. Means may also be attached to the screen for producing whirling currents of liquids. The screen may be formed of two superposed perforated plates, which may be relatively adjusted to place the perforations wholly or partly out of register. Alternatively the screen may be composed of adjustable pivoted slats which may be arranged in oppositely inclined groups.—W. F. F.

Carbon-black and hydrogen; Manufacture of —, R. F. Bacon, B. T. Brooks, and H. Clark, Assignors to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,229,391, Mar. 27, 1917. Date of appl., July 9, 1911.

A JET of liquid hydrocarbon is injected into a zone of sufficiently high temperature to decompose the hydrocarbon into its elementary constituents, which are then continuously removed from the zone by the force of the gas pressure developed, while the carbon-black is still suspended in the hydrogen and in such condition that when it subsides it will have a deep black lustre.—C. A. M.

Pigment. H. A. Gardner, Washington, D.C. U.S. Pat. 1,220,973, Mar. 27, 1917. Date of appl., Feb. 18, 1915.

BARIUM phosphate or other substantially insoluble metallic phosphate is incorporated with zinc sulphide or other insoluble metallic sulphide to form a pigment.—C. A. M.

Hydrocarbon oil; Manufacture of a non-saponifiable unsaturated — from a drying oil. Manufacture of a non-volatile unsaturated hydrocarbon from petroleum. B. T. Brooks and F. W. Padgett, Assignors to Gulf Refining Co., Pittsburgh, Pa. U.S. Pats. (A) 1,220,820 and (B) 1,220,821, Mar. 27, 1917. Date of appl., Aug. 10, 1911.

(A) CARBON dioxide is split off from the free fatty

acids of linseed or other drying oil, leaving an unsaturated hydrocarbon which forms a good film on drying, and is a valuable substitute for linseed oil. (B) A fraction of petroleum oil boiling above about 250° C. is chlorinated sufficiently to obtain dichlorinated compounds of the constituent hydrocarbons, and the latter are heated *in vacuo* to between about 350° and 500° C., in the presence of barium chloride or other catalyst, whereby hydrochloric acid is split off, and a non-volatile unsaturated hydrocarbon drying oil is left.—C. A. M.

Phenols and formaldehyde; Process for obtaining hard products of condensation of —, K. Tarassoff, Moscow, and P. Shestakoff, Petrograd. Eng. Pat. 101,887, Jan. 19, 1916. (Appl. No. 893 of 1916.)

PHENOLS and formaldehyde or its polymers are mixed with oil of turpentine or other liquid terpene products, or with coal or wood tar, or non-phenolic oils obtained in the distillation of coal tar, and the mixture is polymerised or condensed e.g., as described in Eng. Pats. 21,566 and 1921 of 1908 (this J., 1909, 374, 148). The initial stage of the process is carried out at temperatures below the boiling point of the mixture, and in the presence of alkalis, ammonia, or organic bases. The resulting product has good dielectric properties and is not affected by various chemical agents. (See also Eng. Pat. 2122 of 1908; this J., 1909, 252.)—C. A. M.

Preparation of reactive products [shellac substitute] from paraffin hydrocarbons. Ger. Pat. 295,591. See IIA.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber from Eucommia ulmoides. Oliver, A. F. Sievers, J. Amer. Chem. Soc., 1917, 39, 725—731. ETHER readily extracts about 2% of caoutchouc from the bark of *Eucommia ulmoides*; after the solvent has been evaporated, the residue of caoutchouc is slowly soluble in ether (requiring about 10 hours) and also in toluene, chloroform, carbon bisulphide, turpentine oil, carbon tetrachloride, and gasoline, but is insoluble in alcohol. Its rate of solubility in these solvents is slightly different from those of specimens of raw rubber from Ceylon and Siam, respectively.—W. P. S.

Action of ozone on organic compounds [rubber resins]. Harries and others. See XX.

PATENT.

Rubber composition and process for the manufacture thereof. C. Paechetti, Milan, Italy. Eng. Pat. 105,026, Sep. 5, 1916. (Appl. No. 12,538 of 1916.)

A COMPOSITION of rubber or the like is mixed with small lengths of horse hair, hogshair, or bristles, the length of the hairs being about 3 to 4 mm., and the mixture is then vulcanised, to obtain a non-slipping material suitable for belts, pneumatic tyres, and packing rings for steam and water pipes. Preferably the hair is freed from fat prior to admixture with the rubber, etc.—C. A. M.

XV.—LEATHER; BONE; HORN; GLUE.

Wattle bark industry of Natal. Bull. Imp. Inst., 1916, 14, 599—601. (See this J., 1916, 1165.)

THE production of wattle bark in Natal was 1,300,000 cwts. in 1913, corresponding to 2,350,000 cwts. of the green, undried bark. Of this 811,000 cwts. (value £325,000) was imported into the United Kingdom for re-export and home use. Whilst the total production of Natal has naturally

declined since 1913, the quantity used in the United Kingdom has increased remarkably. The most important recent development of the industry has been in the production in Natal of tanning extract. Several patents have been granted, one factory is erected and others are in course of construction. In full work, these factories will be able to deal with two-thirds of the total output of bark. In one of the patented processes the bark is simultaneously crushed between bronze rollers and extracted with hot water. In another the dried or green bark is first finely chopped, then crushed between bronze rollers, and subsequently extracted in large leaching vats. The spent bark is used as fuel.—F. C. T.

Industrial development in United Provinces, India. [Babul pods as tanning material.] Bull. Imp. Inst., 1916, 14, 612—615.

THE Board of Industries recently established in the United Provinces has issued several memoranda on native products and industries, of which one deals with babul (*Acacia arabica*) pods as a tanning material. The difficulty which has hindered the use of these pods for tanning in India has been the great liability of the liquors to fermentation. Experiments made in the technical laboratories of the Department of Industries, United Provinces, have shown that the fermentation can be stopped by boiling the liquors, by keeping them at a low temperature, or by the use of antiseptics such as phenazole or carbolic acid. Phenazole is alkaline, but quite effective if slightly acidified with acetic acid: 0.25% or more should be used, calculated on the tanning material; rather more carbolic acid is necessary. While the fermentation of untreated liquors is quite rapid at 65° F. (18° C.), very little takes place at 50° F. (10° C.), and it is probable that babul liquors would be quite suitable for use in the winter months in India.—F. C. T.

XVI.—SOILS; FERTILISERS.

Soils and fertilisers: The organic nitrogen compounds of —. E. C. Lathrop. J. Franklin Inst., 1917, 183, 465—498. (See this J., 1915, 293; 1916, 1167.)

DETERMINATIONS of the amide nitrogen in a mixture of soil and dried blood (this J., 1916, 1167) showed that the amount increased slightly during the second and third days of the experiment, but decreased by about 70% from the third to the fifth day, indicating that practically all of it was

split off from the dried blood proteins in five days. The initial increase was probably due to the synthetic action of micro-organisms, and the protoplasmic proteins produced by them are far more stable than the protein of dried blood. The nitrogenous organic compounds so far isolated from soils are chiefly primary protein decomposition products. Nitrogen metabolism in plants in so far resembles the metabolism in animals that organic nitrogen compounds are synthesised from pre-existing complex nitrogenous matter: this fact and the related one, that soil organisms are influenced by such compounds, are of great agricultural importance. Recent analyses of cottonseed meal, tankage, and blood meal show that their organic nitrogen content is very similar to that of dried blood, hence it is probable that their decomposition products in the soil are also similar. The principle of the manufacture of processed fertilisers is the same as that of the rendering available of the nitrogenous organic matter of the soil, *viz.*, the partial or complete hydrolysis of proteins; and in general the fertilising effect is proportional to the extent of hydrolysis. Any method which seeks to determine the availability of the nitrogen in an organic fertiliser by measuring the ammonification which takes place in a given time under biological conditions, must be incomplete if it fails to take into account the intermediate products produced by partial hydrolysis.—E. H. T.

Plants: Influence of certain organic substances on the development of —. I. G. Clamian and C. Ravenna. Atti R. Accad. Lincei, 1917, [v], 26, i., 3—7. J. Chem. Soc., 1917, 112, i., 244—245.

THE accessory substances of vegetable organisms, such as glucosides, alkaloids, colouring matters other than chlorophyll, etc., are regarded by some authorities as reserve food materials and by others as excretory products. The authors, who favour the former view, have investigated the influence of certain of these substances on the development of plants. When an organic compound is introduced into an adult plant either by way of the roots or by inoculation into the stem, no apparent external change is produced, provided that the nature and amount of the substance are such that the plant remains alive. The germination of beans and maize on cotton-wool is almost completely inhibited by watering with 0.1% mandelonitrile solution, whereas when an amygdalin solution of corresponding concentration (0.55%) is used, all the seeds germinate like those treated with water. If, however, the mandelonitrile is first administered some days after germination, the plants develop, although comparatively slowly, the height attained being less and the root-growth not so marked; on the other hand, the stems are thicker and the plants more robust, since they are able to live through the winter, whilst those provided with complete nutriment dry up in October. That these plants treated with mandelonitrile are nourished at the expense of the nitrogen of this compound whilst the benzaldehyde undergoes oxidation or other transformation, is shown by the absence of hydrocyanic acid or benzaldehyde, even after the extract of the plant has been treated with emulsin. Hydrocyanic acid in 0.1% concentration retards or prevents the germination of beans and maize, and those plants (about 30%) which grow very soon die. Nicotine tartrate solution containing 0.1% of the alkaloid behaves similarly towards the seeds, and even when it is first applied subsequently to the germination, the plants grow slowly and abnormally. Strychnine tartrate of similar concentration has no apparent influence on the germination of the seeds, but the plants dry up after a few days. The action of caffeine or morphine is similar to that of strychnine.

Soil protozoa and soil sterilisation; Review of investigations in —. N. Kopeloff and D. A. Coleman. *Soil Sci.* 1917, 3, 197—269.

XVII.—SUGARS; STARCHES; GUMS.

Saponin in extracted beetroot. Andriik. Böhm. Zeits. Zuckerind. 1917, 41, 343. Chem.-Zeit., 1917, 41, Rep., 103.

EXTRACTED beetroot slices as obtained from the factories contain when dried below 100° C. about 1.4% of saponin (about 0.1% of the fresh beetroot). It is present in combined form, but can be obtained in pure condition by hydrolysis for 24 hours in the cold with 50% alcohol and 4% of sodium hydroxide, or with 96% alcohol in presence of 2 to 4% of sulphuric acid, or more rapidly by boiling for 2 mins. with the alcoholic acid.—C. A. M.

Ketohexose; Thiobarbituric acid as a reagent for —. G. P. Plaisance. J. Biol. Chem., 1917, 29, 207—208.

THE hexoses are more readily converted into hydroxymethylfurfural than are the aldoses, and the test proposed depends on the detection of the

hydroxymethylfurfural by means of the orange-coloured precipitate which it yields with thiobarbituric acid in hydrochloric acid solution. The substance to be tested is boiled with 12% hydrochloric acid, the solution then cooled, and a few drops of thiobarbituric acid solution (in 12% hydrochloric acid) are added. If a ketohexose was present originally, an orange-coloured precipitate forms gradually. Aldoses may yield a yellow solution with the test, but a precipitate is not formed.—W. P. S.

Starches; Determination of gelatinisation temperatures of — by means of an electrically heated chamber on the microscope stage. A. W. Dox and G. W. Roark, jun. J. Amer. Chem. Soc., 1917, 39, 742—745.

THE heating device employed is a "No. 8, electric incubator for the microscope stage," especially adjusted for temperatures up to 80° C. A piece of asbestos board inserted between the stage and the heating chamber will prevent considerable loss of heat. A small amount of the starch to be tested is placed on a cover glass, moistened with a drop of water, and the cover glass is placed over the depression in a hanging-drop slide; the latter is then supported on two short rods at the bottom of the chamber, which has been heated previously to 60° C., a mica cover, provided with a hole for the objective, is placed in position, and the temperature is increased slowly until anisotropy disappears in all the grains that are large enough to show the characteristic shape and markings. This operation serves as a preliminary orientation. The test is then repeated, starting 5° below the previously noted gelatinising temperature and increasing the temperature at the rate of 1° C. per min. The gelatinising temperature will be found to be slightly below that observed in the preliminary test. The use of a short thermometer is recommended, and owing to variations in the temperature at different parts of the chamber, a correcting factor is found by determining the melting points of such substances as palmitic acid, phthalide, or azobenzene, under the same conditions that prevailed during the gelatinisation tests; the correction will usually be about —3.8° C. The gelatinisation points of the starches from 13 varieties of maize were found to vary from 64.1° to 71.1° C., but concordant results were obtained for each variety.—W. P. S.

Invertase action; Kinetics of —. J. M. Nelson and W. C. Vosburgh. J. Amer. Chem. Soc., 1917, 39, 790—811.

THE velocity of the inversion of sucrose by invertase is directly proportional to the concentration of the invertase and is nearly independent of the concentration of the sugar solution; in the case of very dilute sucrose solutions, however, the velocity increases with an increase of the concentration of the sugar up to 5 grms. per 100 c.c. Experimental results obtained agree with the view that the reaction is a two-phase one and contradict the claim that the kinetics of invertase action conform to the unimolecular law for homogeneous reactions. Adsorption is one of the controlling factors of the kinetics of the action. The inversion of sucrose by invertase is a different type of heterogeneous catalytic reaction from the dissociation of stibine into antimony and hydrogen in the presence of metallic antimony, and the dissociation of molecular hydrogen into atomic hydrogen in the presence of heated metals. (See also Henri, this J., 1906, 131.)—W. P. S.

PATENT.

Aqueous solutions [e.g. massecuite]; Method of evaporating —. R. U. Bunker, Yonkers, N.Y. U.S. Pat. 1,221,022, Apr. 3, 1917. Date of appl., Dec. 8, 1913.

AN aqueous solution, e.g., massecuite, is evaporated in a series of four vacuum chambers. The material is boiled successively in three of the chambers having progressively higher temperatures and lower vacua, and finally in the fourth chamber in which the temperature is lower than in the third. Each chamber is divided into a number of pockets having a vapour space in common, and the charges of material in the pockets, after concentration, are withdrawn separately and transferred to pockets in the next vacuum chamber of the series. The vapour from each chamber is passed into the next chamber, with the exception that the fourth chamber is next to the last in order of progression of the vapour. —W. F. F.

XVIII.—FERMENTATION INDUSTRIES.

Wine; Chemical equilibrium between tartaric acid and dipotassium tartrate as basis for the de-acidification of — with this salt. T. Paul. Z. Elektrochem., 1917, 23, 65—86. (See also this J., 1915, 1159; 1916, 134.)

THE author has studied, from the standpoint of electrolytic dissociation, the reactions involved in the treatment of acid wines with dipotassium tartrate to precipitate excessive amounts of tartaric acid as monopotassium salt (tartar), a treatment first proposed by Liebig, but since undeservedly neglected. The solubility of monopotassium tartrate at 18° C. was found to be 4.903 grms. per litre (of solvent) in pure water, and 3.58, 2.94, and 2.57 grms. per litre in water containing 5, 8, and 10 grms. of alcohol per 100 c.c. One per cent. solutions of tartaric acid in water and in dilute alcohol were treated with dipotassium tartrate in quantities ranging from 0 to the full equivalent of the acid present, and the equilibria produced were accounted for satisfactorily in terms of the known laws of electrolytic dissociation. Small quantities of the dipotassium salt, insufficient to produce any precipitation of tartar, had no effect on the acidity determined by titration, but larger quantities reduced the acidity to an extent proportional to the amount of tartar precipitated. The concentration of hydrogen ions, however, fell to about half its original value on addition of only one-tenth of the amount of dipotassium salt equivalent to the tartaric acid present, and was still further reduced by larger amounts of the salt. Addition of dipotassium tartrate to natural wines of excessive acidity produced substantially similar results, though the fall in the concentration of hydrogen ions was more nearly proportional to the quantity of added salt than in the experiments mentioned above. This method of treating acid wines has less effect on their constitution than the use of calcium carbonate (see this J., 1916, 134). It does not introduce a foreign substance into the wine, nor does it raise the ash- or extract-content appreciably, for the greater part of the added salt is again removed in the form of tartar. If added in the form of a saturated solution, the dipotassium salt immediately exerts its full effect in reducing the concentration of hydrogen ions (on which the acid flavour of the wine depends), although the tartar formed may not begin to separate for some time; the separation is, however, usually complete within 24 hours. The treatment may therefore be simply carried out by adding a saturated solution of dipotassium tartrate in small quantities until the desired alteration of flavour is attained, and then leaving the wine to stand until the tartar separates. —J. H. L.

Wines; White "casse" of —. Fonzes-Diacon. Comptes rend., 1917, 164, 650—652. (See this J., 1917, 468.)

TREATMENT with citric acid does not always prevent the appearance of white casse in wines; the maximum amount which may be added in France is 0.5 gm. per litre, but for some wines manufactured with the aid of sulphurous solutions of ammonium phosphate, 2 grms. of citric acid per litre has been found insufficient. Another method of treatment, now illegal, consists in adding oxalic acid or potassium oxalate. Part of the lime present is thus precipitated, but some oxalic acid always remains in solution and this appears so to influence the equilibrium in solution as to prevent the separation of ferric phosphate.

—J. H. L.

Application of the Komarowsky reaction as a test of purity of concentrated sulphuric acid. See VII.

Vitamine content of brewers' yeast. Seidell. See XIXA.

PATENT.

Sulphite waste liquor; Fermentation of —. A. V. Jernberg, Tidaholm, Sweden. U.S. Pat. 1,221,058, Apr. 3, 1917. Date of appl., Feb. 6, 1917.

SULPHITE waste liquor is prepared for fermentation by the addition of a neutralising agent and a suitable quantity of calcium cyanamide, previously treated with water or steam, corresponding to the need of nitrogen and the acidity of the lye.

—J. F. B.

XIXA.—FOODS.

Butter; Method of preserving —. T. Paul. Chem.-Zeit., 1917, 41, 74—75.

THE butter is melted at 40° to 45° C. and the fat separated, and while still warm stirred with salt (30 grms. per lb. of fat) which has been strongly heated and then cooled to about 45° C. The vessel is allowed to stand for 2 to 3 hours in a warm place so that the fat remains fluid, and the mixture is meanwhile frequently stirred. It is then filtered through cotton wool in a hot water funnel, and the filtered fat is placed in bottles, which should be filled to within 1 to 2 cm. of the stopper, and kept in the dark in a cool place. To reproduce the butter, the fat is melted at about 40° C., and 85 parts by weight is vigorously shaken with 15 parts of fresh milk for 2 to 3 mins., and the emulsion is rapidly cooled by means of ice-water. Butter fat thus preserved will keep for at least a year. —C. A. M.

Calcium in blood and milk; Rapid method for determining —. H. Lyman. J. Biol. Chem., 1917, 29, 169—178.

FIVE c.c. of blood, or the same quantity of a mixture of 10 c.c. of milk and 190 c.c. of water, is mixed with 15 c.c. of a 6.5% solution of trichloroacetic acid, the mixture is filtered, 10 c.c. of the filtrate is neutralised with ammonia, and a slight excess of dilute nitric acid is added, followed by oxalic acid and sodium acetate. After 18 hours, the precipitated calcium oxalate is separated by centrifugal action, washed with ammonium oxalate solution, dissolved in a very small quantity of nitric acid, the solution mixed with an excess of ammonium stearate solution, and the turbidity produced compared in a nephelometer with that given under similar conditions by a known amount of calcium oxalate dissolved in nitric acid. —W. P. S.

Casein; Solubility of — in dilute sodium chloride solutions. S. Ryd. Z. Elektrochem., 1917, 23, 19—23.

WHEN pure casein is dissolved in standardised sodium hydroxide solution, and standard hydro-

chloric acid then added, after the free alkali has been neutralised the sodium caseinate is decomposed, yielding free casein and sodium chloride. The separation of the casein produces an opalescence before actual precipitation takes place. If, owing to the presence of dissolved sodium chloride, an excess of casein is dissolved, the opalescence is observed before the neutral point, as given by phenolphthalein, is reached (*i.e.*, before all the caseinate has been decomposed by the acid); if the amount of dissolved casein is deficient, then more acid than corresponds to the alkali used must be added to cause the opalescence. This is the principle of a method described for tracing the effect of sodium chloride upon the solubility of casein in water. The titration is performed in a closed cylindrical jar provided with a tightly-fitting cork through which pass a mechanical stirrer, a thermometer, and the prolongations of the jets of two burettes containing respectively the acid and the alkali. Experimenting with sodium chloride solutions of 22 different concentrations, it was found that the solubility rose rapidly with the concentration of the chloride up to 0.115 gm.-mol. per litre, and that above this concentration it fell, at first rapidly, then more slowly, and finally tended to remain constant.—E. H. T.

Canned meat; Sterilisation of —, A. Kossowicz. *Chem.-Zeit.*, 1917, **41**, 211—213.

MEAT packed in tins of 250 c.c. capacity ought to be sterilised for at least an hour, of which not less than 45 mins. should be at a temperature of 120° to 127.5° C., corresponding to a pressure of 1 to 1½ atmos. A pressure of 1 atmos., corresponding to about 120° C., would be sufficient, but it is necessary in practice to make allowance for possible unobserved reduction of the steam pressure, especially when several autoclaves are working simultaneously, and it is therefore advisable to use a pressure of 1½ atmos. At 1½ atmos. the meat often becomes too soft and too readily disintegrated. In the case of larger or smaller tins the duration of the sterilisation is correspondingly varied in accordance with the results of experiments. The empty tins should be tested for pinholes under water at a pressure of 3 atmos., and then washed in running hot and cold water. After sterilisation they are wiped free from fat, etc., immediately after removal from the autoclaves, and are then set aside for observation, before packing, for at least 14 days at 20° to 30° C. At temperatures below 20° C., the observation period must be extended to 4 to 8 weeks. After the removal of blown tins, etc., the remainder is cleaned, coated with a thin film of vaseline as a protection against rust, and packed.—C. A. M.

Oat kernel; Nature of the dietary deficiencies of the —, E. V. McCollum, N. Simmonds, and W. Pitz. *J. Biol. Chem.*, 1917, **29**, 311—351.

FEEDING experiments on rats were made with oat kernels and purified food principles. It was found that the oat kernel contained proteins of a poorer quality than those of maize and wheat kernels. These proteins were not supplemented very satisfactorily by the addition of casein, but gelatin in about equal quantity gave very good results. The hulled oat kernel does not induce growth, but with addition of butter fat causes a slow increase. The addition of a single food principle such as protein, inorganic salts, etc., does not induce growth, but the addition of two principles does so, provided one of them is a salt mixture. The oat kernel causes injury to animals when their diet is of such a kind as to lower their vitality.—J. H. J.

Cottonseed as food; Use of —, T. B. Osborne and L. B. Mendel. *J. Biol. Chem.*, 1917, **29**, 289—317.

FEEDING experiments were made on white rats

with cottonseed meal and flour, both when used as the sole protein in the diet and when used in small quantity to supplement less efficient proteins. In all cases satisfactory growth of the animals took place. Cottonseed kernels were, however, unsatisfactory, due to the presence of a constituent which was either directly poisonous or else so unpalatable as to cause the animals to refuse to eat the food. The injurious constituent could be extracted by ether, and the extracted kernels, and kernels which had been steamed for some hours, proved satisfactory foods. Cottonseed oil was harmless.—J. H. J.

Inositolphosphoric acids of cottonseed meal. J. B. Rafter. *J. Amer. Chem. Soc.*, 1917, **39**, 777—789.

AN inositolphosphoric acid corresponding in composition with inositoltriphosphoric acid, $C_6H_6(OH)_3(H_2PO_4)_3$, was isolated from certain samples of cottonseed meal, but this compound does not appear to be a constant constituent of the meal. From other samples of the meal an inositolphosphoric acid was separated which corresponded in composition with inositolpentaphosphoric acid, $C_6H_6(OH)(H_2PO_4)_5$, or equally well with the acid, $C_{12}H_{43}O_{12}P_9$; in view of the theoretical possibility of the existence of the pentaphosphoric acid, it appears best to ascribe to it the former formula. (See also this J., 1915, 630.)—W. P. S.

Vitamine content of brewers' yeast. A. Seidell. *J. Biol. Chem.*, 1917, **29**, 145—151.

ASSUMING that all the nitrogen contained in fullers' earth which has been shaken with the filtrate from autolysed yeast is derived from vitamine, the maximum quantity of the latter which can be present in the original filtrate is 0.18 gm. per 100 c.c. In the case of pigeons, the vitamine deficiency of an exclusive diet of polished rice is just replaced by daily doses of 1 c.c. of the clear filtrate from autolysed brewers' yeast; equivalent doses of freshly-pressed yeast do not replace the vitamine deficiency of polished rice, and the autolytic process appears, therefore, to influence favourably the activity of the vitamine of brewers' yeast.—W. P. S.

Arginine in proteins; Method for accurately estimating —, B. C. P. Jansen. *Chem. Weekblad*, 1917, **14**, 125—129. *J. Chem. Soc.*, 1917, 112, ii, 184.

ARGININE can be estimated quantitatively in proteins by the action of arginase and urease on the hydrolysed product after elimination of the ammonia. The arginase decomposes the arginine, with formation of an equimolecular proportion of urea, which is converted by the urease into ammonium carbonate.

Pectins; Constitution and technical importance of —, F. Ehrlich. *Chem.-Zeit.*, 1917, **41**, 197—200. (See also Schryver and Haynes, this J., 1917, 517.)

"CRUDE pectin" may be separated from the residual cellular membrane of the beetroot after expression of the juice and washing. It consists of two constituents which can be readily separated. One of these is a kevo-rotatory araban, $[\alpha]_D = -171$ to -121 , which when boiled with dilute organic acids yields dextro-rotatory *l*-arabinose. Since the araban is readily soluble in water, and is not precipitated by lime or lead acetate, it must pass into the syrups and molasses in the sugar factories, and probably contributes to the apparent losses of sugar as indicated by the polarisation tests. The other and main constituent of the crude pectin is a dextro-rotatory calcium-magnesium salt of pectic acid, and has the same properties as that isolated from the crude pectins of apricots and of orange peel. It contains about 6% of ash.

and has a specific rotation of $[\alpha]_D = +150$ to $+155$. On adding alcohol and hydrochloric acid to its aqueous solution the free pectic acid is precipitated as a powder, which when washed with alcohol and ether and dried at 100°C . still contains about 0.1 to 0.6% of ash, and has a composition, calculated on the ash-free substance, of C, 43.70; H, 5.45; and O, 50.85%. It contains about 9% of methoxyl, behaves as a weak acid, and has a specific rotation of about $[\alpha]_D = +220$. Pure pectic acid thus separated from different kinds of vegetable substances was free from pentoses, though it gave the pentose reactions with orcinol and resorcinol and yielded a considerable amount of furtural when distilled with hydrochloric acid. On oxidation with nitric acid it yielded up to 50% of mucic acid, attributable to the presence of galactose. The solution gave Tollens' naphthoresorcinol reaction for glucuronic acid. Hydrolysis of the pectic acid with acids and alkalis showed that it contained a compound of *d*-galactose with an isomer of glucuronic acid, *d*-galacturonic acid (see Suarez, following abstract). By restricted hydrolysis with 0.5 to 1% oxalic acid solution, a dextro-rotatory galactose-galacturonic acid,

was obtained. This is an amorphous monobasic acid which is soluble in water, gives the orcinol and naphthoresorcinol reactions, and yields much mucic acid on oxidation. Complete hydrolysis of pectic acid is best effected by boiling with oxalic acid solution under pressure (130 to 140 $^\circ\text{C}$). On treating pure pectic acid with an excess of sodium hydroxide solution, a gelatinous deposit of a sodium salt is obtained, and by treating this with hydrochloric acid a nearly insoluble acid with very high specific rotation, $[\alpha]_D = +270$, is obtained, which appears to be formed by the elimination of 3 mols. of water from 1 mol. of *d*-galacturonic acid: $4\text{C}_6\text{H}_{10}\text{O}_7 - 3\text{H}_2\text{O} = \text{C}_{24}\text{H}_{34}\text{O}_{25}$. For this acid, which contains four free hydroxyl groups, the name of *d*-tetragalacturonic acid is suggested. It gives all the colour reactions of the pentoses and glucuronic acid, and yields 70%, or more, of its weight of mucic acid on oxidation. When hydrolysed with dilute oxalic acid under pressure, it yields a new stereoisomeric *d*-glucuronic acid, — *d*-galacturonic acid—which gives all the typical reactions of glucuronic acid, such as reduction of Fehling's solution in the cold. Unlike glucuronic acid, it forms crystalline phenylhydrazine derivatives, and readily soluble compounds with alkaloids, such as the cinchonine salt, which crystallises in rhombic needles (m. pt. 158°C) and has $[\alpha]_D = +134$. These results indicate that the natural pectin of vegetable cell membranes must be regarded as the calcium-magnesium salt of a complex anhydro-arabino-galactose-methoxytetragalacturonic acid. With regard to the utilisation of pectin, it is pointed out that the dry cellular membrane of the beetroot contains up to 25 or 30% of crude pectin, and that there would be no difficulty in associating its production with the manufacture of sugar. Pectin substances are suitable for fodder, and it may be possible to treat crude pectin by hydrolysis or otherwise in such a way as to render at least the galactose group available for human food.

—C. A. M.

Glucuronic acid [from lemons]: An isomer of —. M. L. Suarez, Chem.-Zeit., 1917, 41, 87.

The expressed pulp of lemons was finely divided, washed with cold water until the washings no longer reduced Fehling's solution, and 1 kilo. of the pressed mass heated for $1\frac{1}{2}$ hours in an autoclave at 120°C . with 5 kilos. of water containing 10 grms. of sulphuric acid, and then again pressed. The yellow filtrate was boiled with barium carbonate, filtered from barium sulphate, and con-

centrated to 300 c.c. under reduced pressure. The precipitate which formed was removed, the residual solution was poured into 2 litres of absolute alcohol, and the resulting precipitate was separated and purified by reprecipitation with alcohol from an aqueous solution. It was a pale-yellow non-hygroscopic powder, with a composition corresponding with the formula, $\text{Ba}(\text{C}_6\text{H}_5\text{O}_7)_2$. Its aqueous solution was dextro-rotatory, had a strong reducing action, and gave the reactions of glucuronic acid with Tollens' naphthoresorcinol reagent, and with phloroglucinol and orcinol, but it was not possible to obtain the *p*-bromophenylhydrazine compound nor to prepare from it the anhydride of glucuronic acid, whilst oxidation by Thierfelder's method yielded mucic acid. This new acid, isomeric with glucuronic acid, did not yield a definite osazone with phenylhydrazine.

Separation and determination of butyric acid in biological products. Phelps and Palmer. See XX.

PATENTS.

Emulsions [for margarine]: Preparation of —. S. H. Blichfeldt, Southall, Middlesex, Eng. Pat. 104,899, Mar. 17, 1916. (Appl. No. 1017 of 1916.)

AN aqueous vehicle for use in the manufacture of a concentrated fatty emulsion to be used for the production of margarine, is obtained from linseed. The seed, or the outer coating or cortex of the seed, is treated with 100 parts of hot or boiling water to 1—5 parts of seed, a "ropy" solution of the mucous material in the cortex being obtained. The water used may be slightly alkaline. The margarine may be prepared by the use of this solution according to the methods described in Eng. Pats. 23,653 and 25,245 of 1913 and 18,048 of 1914 (this J., 1911, 1167 and 1218). —W. F. F.

Milk; Method of treating —. C. H. Campbell, Assignor to Borden's Condensed Milk Co., New York, U.S. Pat. 1,221,024, Apr. 3, 1917. Date of appl., July 25, 1913.

A BODY of milk is maintained at a temperature above normal by a rigid heated surface in contact with it. The adhering thickening milk is wiped from the heated surface periodically at frequent intervals, and returned to the body of milk, so that it is prevented from coagulating, burning, or exposure to the air, and heat transference from the heated surface is facilitated. —W. F. F.

Sterilising foods; Apparatus for electrically —. J. Haussen, Christiania, Norway. Eng. Pat. 101,801, Oct. 12, 1916. (Appl. No. 11,521 of 1916.) Under Int. Conv., Oct. 12, 1915.

THE apparatus, which is specially adapted for the sterilisation of split cod, consists of an inclined channel into which the fish are fed from a hopper and down which they pass between metal contact plates in the floor and spring projections from the top of the channel. The springs are attached to a metal shaft which crosses the channel and is electrically connected to an induction coil, to which the plates in the floor of the channel are also connected. An alternating current of high voltage is sent through the coil. —J. H. J.

XIXB.—WATER PURIFICATION; SANITATION.

Magnesium: Titration of — [in water analysis]. F. W. Brucknüller, J. Amer. Chem. Soc., 1917, 39, 610—615.

THE estimation of magnesium in water analysis can be effected satisfactorily by the following

methods in the solution remaining after precipitation of the calcium: (a) The solution is evaporated to dryness, and ammonium salts decomposed by heating. The residue is dissolved in a small volume of water, acidified with hydrochloric acid, and after filtering, made slightly alkaline with ammonia. Microcosmic salt solution is slowly added to the cold solution, with stirring, and after the precipitate has formed, a quantity of ammonia solution equal to one-third of the total volume added, is introduced, and the solution allowed to stand 18 hours. The precipitate is filtered off with the aid of suction and washed with 25 c.c. of alcohol. After transferring with hot water to a beaker, a known excess of $N/10$ hydrochloric acid is added and the excess titrated back with $N/10$ sodium hydroxide using methyl orange as indicator. (b) The solution is entirely freed from ammonium salts by evaporation and ignition, the residue dissolved in a small quantity of hydrochloric acid, and the solution filtered. The solution is cooled, made alkaline with ammonia, which is free from ammonium salts, and an excess of 10 c.c. added. A 10–20% excess of sodium arsenate is added slowly and with vigorous stirring which is continued for about 10 minutes after no further precipitation has taken place. The solution is allowed to stand in a cool place to allow the precipitate of magnesium ammonium arsenate to settle, and, after filtering and washing with 3% ammonia water, the precipitate is dissolved in hot water, and 10 c.c. of concentrated hydrochloric acid and 0.3 gm. potassium iodide added for every 100 c.c. of liquid. The liberated iodine is titrated with $N/10$ thiosulphate. (c) The precipitate of magnesium ammonium arsenate obtained as in (b), after washing with dilute ammonia, is dissolved in hot water and the solution transferred to an Erlenmeyer flask fitted with a trap. An excess of potassium iodide and 10 c.c. of sulphuric acid (1:1) are added and the whole boiled rapidly until iodine vapours are no longer visible. While still hot, the trace of iodine remaining is destroyed with sulphurous acid and the whole cooled quickly. The acid solution is neutralised with $N/10$ sodium hydroxide, using phenolphthalein as indicator, and adding from time to time a solution of sodium phosphate. When titration is complete, the volume of phosphate solution added should be equal to one-half the volume of the iodine solution. The total volume should be about 250 c.c., and if greater than this more phosphate must be added in proportion to keep the hydrogen ion concentration at the right value. The arsenious acid is titrated as usual with $N/10$ iodine. For every 100 c.c. of $N/10$ iodine, 11 grms. of $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ is necessary in a volume of 250 c.c. to keep the ratio $\text{Na}_2\text{HPO}_4/\text{NaH}_2\text{PO}_4 = 2$ at the end point, which ensures a hydrogen ion concentration of 10^{-7} .

—J. N. P.

Polable water for military purposes. A. Vila. J. Pharm. Chim., 1917, 15, 277–282.

THE author describes a simple apparatus for use in treating water by means of hypochlorite, the amount of reagent supplied being regulated automatically according to the flow of the water.

Disinfecting power of complex organic mercury compounds. III. Mercurised phenols. W. Schrauth and W. Schoeller. Z. Hyg. Infektkrankh., 1916, 82, 279–288. J. Chem. Soc., 1917, 112, i., 241–242.

THE results previously obtained by the authors with the substitution products of sodium *o*-hydroxymercuribenzoate, $\text{HO} \cdot \text{Hg} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{Na}$ (this J., 1912, 297), indicate that the disinfecting power would be increased by the substitution of the less acidic phenolic hydroxyl for the carboxyl group.

Experiments have now been performed with two mercurised phenols, and also with substances which contain, in addition to one or two hydroxymercuri-groups, halogen, alkyl, or methoxy-groups. The previous observations have been confirmed in all cases, and the influence of the position of the substituent in the benzene nucleus has been investigated. It has been further observed that the relative positions of the hydroxymercuri- and phenolic groups are important. Considerable differences in the disinfecting power of the three isomeric mercurised cresols have been noticed; the *m*-derivative is most potent, whilst sodium *o*-hydroxymercuriphenoxide is more active than the isomeric para-compound. In the case of sodium dihydroxymercuriphenoxide (providol), the entrance of a second hydroxymercuri-group into the benzene nucleus considerably increases the disinfecting power. The substances were prepared by treating the phenol with mercuric acetate in alcoholic solution; the recrystallised products were dissolved in the calculated amount of sodium hydroxide and diluted with water to the required mercury content. Among the preparations examined, sodium *o*-chlorohydroxymercuriphenoxide and sodium dihydroxymercuriphenoxide have been found particularly active. Their practical importance is increased by the fact that their disinfecting power, in contrast to that of all previously investigated compounds, is not diminished in the presence of soap, and that they are permanently unchanged in soaps which consist chiefly of the sodium salts of saturated fatty acids. Medical preparations of this kind (apidol- and providol-soap) keep well.

New applications of thymolphthalein and naphtholphthalein [in determination of true neutrality in waters]. Moir. See XXIII.

PATENTS. •

Water softening and purifying apparatus. W. Paterson, London. Eng. Pat. 104,919, Mar. 22, 1916. (Appl. No. 4280 of 1916.)

THE apparatus is especially suitable as a small plant for domestic use. It consists of a closed tank on which is supported a smaller closed tank containing the measuring and reagent-adding apparatus. The two tanks are connected by an opening through which the water, to which the reagent has been added, passes into the larger tank. The exit from the large tank is by means of a submerged pipe with a valve controlled by a ball float. The pipe passes upwards to the purified water tank situated at a higher level; a float in this tank controls a valve on the raw water supply pipe entering the measuring apparatus. As the water in the large tank accumulates, the air above it is compressed, and when the water rises to a certain level, the valve on the exit pipe is opened and the water rises in the exit pipe and enters the purified water tank. For the addition of the reagent, a small vessel is provided on the top of the reagent tank, with openings to the air and the reagent tank. In another form of the apparatus, the raw water pipe has a valve which is connected with the air space in the large tank, the pressure in this space closing the valve at a fixed point. The exit pipe, at its termination in the purified water tank, is provided with a ball float valve, actuated by alterations of the level of the water in the tank.—J. H. J.

Softening water: Apparatus for —. L. D. Kinzig, Dayton, Ohio. Assignor to Optenberg Iron Works, Sheboygan, Wis. U.S. Pat. 1,220,129, Mar. 27, 1917. Date of appl., July 10, 1916.

THE addition of the reagent is controlled by a tank of water containing a float connected to the discharge pipe from the tank. This pipe has a

restricted opening at its inlet end and is kept by the float at a fixed distance below the level of the water, which is thus discharged at a uniform rate. The float is connected also to the discharge pipe of the reagent tank which is kept at the surface of the reagent and is lowered in unison with the discharge from the control tank.—J. H. J.

Trade waste effluents [from benzol purification]: Purification of —. J. T. Sheard, Sheffield. Eng. Pat. 104,999, July 8, 1916. (Appl. No. 9636 of 1916.)

THE process is applicable to the waste liquid from a benzene rectification still. The waste is made alkaline if necessary, 0.5–1% of alum in solution is added to it, and the mixture well agitated. It is then passed into a settling tank, and when clear, the water is run off through a pipe in the side. The bottom of the tank slopes to an outlet, through which the sludge is withdrawn.—J. H. J.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Digitalis leaves: New reaction for the water-soluble, active glucoside from —. F. Wratschko. Z. allg. Oesterr. Apoth.-Ver., 1916, 54, 263. J. Chem. Soc., 1917, 112, ii., 182.

A FEW c.c. of orcinol-hydrochloric acid reagent (0.2 gm. of orcinol, 100 c.c. of concentrated hydrochloric acid, 4 drops of ferric chloride solution) are heated to boiling, a few drops of the liquid under investigation are added, and the mixture is shaken. A green to blue colour develops, or, at greater concentration, a dark precipitate is formed. The solution is treated with an equal volume of water and shaken with amyl alcohol, whereby the latter is coloured green to dark blue; in the course of a few hours, this colour changes to a more stable lilac to carmine-red tint. The intensity of the colour is dependent on the "digoside" content of the liquid under investigation. The reaction is very sensitive. In the rare case in which the presence of free pentoses is considered possible, a preliminary extraction of the active glucoside with chloroform is necessary; the chloroform is removed, the residue dissolved in alcohol, and the solution tested as described. *Strophanthus* tincture and the aqueous and chloroform extracts of *Strophanthus* seeds also show this reaction.

Narcotic and anæsthetic drugs: Tests for certain —. E. H. Hankin. Indian J. Med. Research, 1916, 4, 237–255. J. Chem. Soc., 1917, 112, ii., 184.

COLOUR reactions of a large number of alkaloids, narcotic substances, etc., are recorded, and more particularly those given by cycloform, β -eucaine, orthoform, nirvanine, anæsthesine, novocaine, holocaine, acaine, stovaine, and alypine. Nitric acid gives a yellow coloration with cycloform, reddish-brown with holocaine, and brownish-black with acaine. Alypine, cocaine, tropacocaine, and α -eucaine yield red crystals when their solutions are mixed with alum solution and the mixtures added to potassium permanganate crystals on a microscope slide; β -eucaine and stovaine form red, oily drops with this reagent. Most of the substances give a white precipitate when treated with Fehling's solution. Reactions with sulphuric acid and potassium iodate, sulphuric acid and hexamethylenetetramine, and with bromine are also described.

Emodin: Identification of drugs containing —. G. D. Beal and R. Okey. J. Amer. Chem. Soc., 1917, 39, 716–725.

CASCARA, RUMEX, RHUBARB, FRANGULA, SENNA, and

ALOES are the best known members of the group of drugs which contain some derivative of a methylanthraquinone, such as emodin, chrysophanic acid, or their isomers, or glucosides yielding these compounds on hydrolysis, and the following scheme is suggested for the identification of these drugs. The drug is extracted with boiling 50% alcohol and the alcoholic solution is divided into three portions: one of these is extracted with benzene, then with amyl alcohol; another portion is extracted with ether, and the third portion is reserved. A portion of the benzene extract is shaken with ammonia, when the formation of a deep violet-red coloration and precipitate indicates the presence of rhubarb. The benzene solution of rhubarb gives a yellow precipitate with lead acetate, which turns red when treated with an alkali, whilst the precipitates obtained from other drugs remain white. A portion of the amyl alcohol extract when shaken with concentrated ammonia exhibits a red coloration and a green fluorescence in the presence of aloes or of freshly-prepared cascara extract. If the red coloration is obtained, another portion of the amyl alcohol extract is treated with mercurous nitrate solution; a red coloration indicates aloes, and this may be confirmed by the copper sulphate, hydrogen peroxide, and borax tests. The presence or absence of cascara may be ascertained by evaporating a portion of the benzene or amyl alcohol extract, nitrating the residue, and treating the product with stannous chloride; cascara gives a deep red coloration, aloes a yellow-brown. The presence of senna is indicated by the formation of a red coloration when a portion of the ether extract of the drug is shaken with saturated nickel acetate solution. If the solution retains its green colour and gives a green precipitate when treated with potassium hydroxide, rumex is present, but the ethereal and aqueous layers must be well mixed when the alkali is added to render this test trustworthy. If the mixture with potassium hydroxide results in the formation of a violet precipitate, the presence of senna is indicated, whilst with rhubarb or frangula it will be red-violet, and with cascara dark orange-red. Rhubarb and frangula give orange coloured solutions before the alkali is added, and the ethereal layer, after the addition of the alkali, becomes colourless except in the presence of rhubarb. If the above tests do not give conclusive evidence as to the composition of the drug, a portion of the ether extract is nitrated, then reduced with stannous chloride, and kept at 100°C. Senna gives a green residue, aloes a brown one, cascara red, and rumex, rhubarb, and frangula violet-red residues. The residue from phenolphthalein, should this be present, is lemon yellow. If these residues are washed with water and then treated with sodium hypochlorite, the senna residue alone yields a red coloration, the others turning yellow. Phenolphthalein gives a red coloration when the extracts are treated with ammonia or other alkali, but this coloration disappears when 30% sodium hydroxide is added, whilst the colorations given by anthraquinone derivatives are not affected by concentrated alkali solution.—W. P. S.

Cignolin as a remedy for psoriasis. P. G. Unna. Dermatol. Wochenschr., 1916, 62, No. 6—8. Chem.-Zeit., 1917, 41, Rep., 99.

CIGNOLIN (1,8-dihydroxyanthranol) has a much more energetic action upon the skin than its 3-methyl derivative, chrysarobin. The dihydroxy derivatives, chrysarobin and cignolin, are both greatly superior in this respect to anthranol and 2-hydroxyanthranol. The reduced compounds, dihydroanthracene, dihydroanthranol, and oxanthrone, are inactive against psoriasis.—C. A. M.

Lichens and their characteristic constituents: Contribution to the knowledge of —. O. Hesse, J. prakt. Chem., 1916, 94, 227–270.

SEVERAL varieties of lichens have been examined, chiefly by extraction with ether or other solvents, and small quantities of characteristic acids have been isolated. From *Evernia furfuracea* var. *olivetorina* were obtained about 0.25% of atranorin, 2% of olivetoric acid, and very small quantities of olivoric and apolivoric acids. From *Parmelia saxatilis* var. *refriga* were obtained 0.2% of usnetic acid and 6.4% of parmatic (saxatilis) acid. From the variety *omphalodes* the same acids were extracted, also lobaric acid, the lactone of usnetic acid. From *Peltusaria communis*, var. *rufifusa*, a bitter-tasting lichen, salicic acid was the principal constituent isolated. *Cetraria nivalis* from Norway yielded on extraction with ether 1.8% of *l*-usnic acid and a new acid, nivalic acid. The carbohydrates of this lichen have been studied and 11% of carbohydrates readily soluble in hot water, consisting of about one-fourth of lichenin and three-fourths of a new carbohydrate, *l*-lichenidin, were obtained. Lichenin, $C_{12}H_{16}O_8$, melts at about 275° C. with decomposition and is optically inactive in aqueous alkaline solution; on hydrolysis it yields only dextrose. Lichenin has the composition of a disaccharide and in borax solution shows $[\alpha]_D^{20} = +68$; it also yields only dextrose on hydrolysis. *Cetraria islandica* (Iceland moss) yields on extraction with ether proto-a-lichesteric acid, which when subjected to a temperature higher than 45° C. is converted more or less into α -lichesteric acid, $C_{12}H_{16}O_8$, m. pt. 124° C., which again is converted into dilichesteric acid. From Iceland moss there is extracted by acetone the potassium salt of fumaroprotocetraric acid, which is readily split up into acid potassium fumarate and cetraric acid; the latter does not occur in the free state. The cold-water soluble carbohydrates of Iceland moss include, lichenin, *d*-lichenidin, $[\alpha]_D^{20} = +15.1$, and lichenoin, $C_{12}H_{16}O_{10}$, $[\alpha]_D^{20} = +202.7$, which on hydrolysis yields dextrose and a carbohydrate, $C_{12}H_{16}O_8$, which gives a crystalline derivative with barium hydroxide. On boiling with water and a little sodium carbonate the lichen loses about 61%, and the residue is largely hydrolysable by dilute acid, yielding mainly dextrose, some galactose, and a very little mannose.—J. F. B.

Heart lecithin: Nitrogenous hydrolysis products of —. C. G. MacArthur, F. G. Norbury, and W. G. Karr, J. Amer. Chem. Soc., 1917, 39, 768–777.

HEART lecithin is possibly identical with brain lecithin, since the two contain about the same amounts of main constituents. On hydrolysis, heart lecithin yields about 12% of its nitrogen in a form insoluble in water; about 50% of the soluble nitrogen is present as choline and the remainder as amino-ethyl alcohol. Traces of ammonia and amino-acids found in the hydrolysed solution are probably derived from impurities and are not part of the lecithin molecule. (See also Parrish and MacArthur, this J., 1916, 556.)

—W. P. S.

Amines and their derivatives: Certain products of the action of formaldehyde and a bisulphite on aromatic —. Action of alkalis and acids on sodium *p*-phenetidinomethanesulphonate. R. Lepetit, Atti R. Accad. Lincei, 1917, [v], 26, i., 126–132, 172–171. J. Chem. Soc., 1917, 112, i., 197–199.

THE action of dilute sodium hydroxide solution on sodium *p*-phenetidinomethanesulphonate (neuralteine) (Eng. Pat. 24,389 of 1908; this J., 1909, 490) has been investigated, and it was found that the reaction proceeds quantitatively according to the equation: $2C_{12}H_{13}O-C_6H_4-NH-CH_2-SO_3Na$

$+ 2NaOH = (C_{12}H_{13}O-C_6H_4-NH)_2CH_2 + CH_2O + H_2O + 2Na_2SO_3$. Other arylaminomethanesulphonates undergo the same reaction, which represents a good general method for preparing imides. If pure methanesulphonates are used, the di-imides are obtained in a pure state, but on recrystallisation the melting point becomes lowered, owing to decomposition. The action of boiling dilute hydrochloric acid on *p*-phenetidinomethanesulphonic acid yields *p*-phenetidine hydrochloride and a substance which crystallises in pale yellow, shining needles, and is the hydrochloride of a sulphur-free base, $C_{18}H_{20}O_2N_2$, m.pt. 140° C., exhibiting anæsthetic properties. When *p*-phenetidinomethanesulphonic acid is boiled with water alone, sulphur dioxide and formaldehyde are evolved, the residual product being the *p*-phenetidinomethanesulphonate of the above base.

$C_{18}H_{20}O_2N_2 \cdot C_{12}H_{13}O-C_6H_4-NH-CH_2-SO_3H$, which crystallises in white needles, m.pt. 160–161° C., and exerts a pronounced and moderately persistent anæsthetic action.

Ozone: Action of — on organic compounds. C. Harries, H. Neresheimer, H. von Splawa-Neyman, R. V. Stanford, and E. Paulsen, Chem. Zentr., 1916, ii., 991–995. J. Chem. Soc., 1917, 112, i., 211–211.

Action of ozone on certain terpenes (see also this J., 1916, 707).—The action of ozone on *d*-limonene in carbon tetrachloride solution leads to the formation of a solid diozonide, which when dissolved in ethyl acetate leaves a small residue, probably consisting of oxozonide; the latter passes after some time into the di-ozonide of formula $C_{10}H_{16}O_6$. This substance forms a white mass, m.pt. 60–65° C., $[\alpha]_D^{20} = -9.32$, in chloroform solution, which decomposes violently at about 85° C. Short treatment with boiling water or dilute acetic acid transforms the ozonide into a keto-ozonide, $C_{10}H_{14}O_4$, which is a syrup; protracted treatment with boiling water leads to the formation of a diketozonide.

Oxidation of the ozonide by chromic acid in acetic acid solution at 50–60° C. leads to the formation of β -diacetylvaleric acid. In addition to the fairly stable normal ozonides, the ketones yield highly explosive ozonide peroxides. A mixture of normal ozonide and ozonide peroxide, a yellow explosive liquid, is formed by ozonising pulegone in chloroform solution, which is converted by water into β -methyladipic acid. The latter substance, $n_D^{20} = +2.5$ (in 33% aqueous solution, *l*, 1), is also obtained by evaporation of the chloroform solution of the mixture. A solution of carvone in carbon tetrachloride is converted by ozone into the oily carvonediozonide, which, when further ozonised in the same solvent, yields carvonediozonide peroxide, an unstable, yellow syrup, which explodes after a few hours in a freezing mixture, more rapidly on contact with ice-water, and within thirty to thirty-five seconds after mixture with water at 40° C. Formaldehyde is formed during the explosion, together with an oil, $C_9H_{12}O_3$, which in all probability is the diketozonide. Total decomposition of the diozonide by steam yields 3-acetylglutaric acid (or its ketodilactone), which is also formed from the diketozonide and boiling water.

Aldehyde from pinene (see this J., 1909, 440).—Pinonaldehyde, $C_{10}H_{16}O_2$, is a pale yellow oil, b.pt. 115–125° C., sp. gr. at 19.4° C. 1.022, $n_D^{20} = 1.46867$; $n_D^{25} = 1.46531$; $[\alpha]_D^{20} = +14.67$. It is readily volatile with steam, reduces cold silver and Fehling's solutions, and is oxidised by air with formation of pinonic acid. It is readily changed by acids and alkalis or by gentle heating. Pinonic acid, obtained by oxidation of the aldehyde with aqueous potassium

permanganate, is an oil, b.pt. 180° — 185° C. at 12 mm., $[\alpha]_D^{20} = +3.9^{\circ}$ in chloroform solution. The crystalline semicarbazone, $C_{11}H_{15}O_3N_3$, has m. pt. 204° C. Nopinone, pleasant-smelling oil, $[\alpha]_D^{20} = -45^{\circ}$ (semicarbazone, m. pt. 167° C.; benzylidene derivative, m. pt. 106 — 107° C.) is obtained by oxidising the previously described (*loc. cit.*) oil (obtained by fusion of pineneozonide) with permanganate.

Degradation of sericin by ozone.—When sericin is ozonised in aqueous solution, the products of fission only account for 65% of the original material. The sole uniform product which is formed is a polypeptide, which, after purification by repeated solution in water and precipitation with methyl alcohol, has $[\alpha]_D^{20} = -60.1^{\circ}$, C = 43.9%, H = 5.85%, N = 17.5%. Determinations of molecular weight lead to the formula $C_{29}H_{48}O_{16}N_{10}$. Hydrolysis of the polypeptide by acids yielded: CO_2 , 8.8%; NH_4Cl , 9.2%; glycine, about 0.5%; alanine, about 1%; valine (or leucine), about 0.3%; serine, 13.1%; aspartic acid, 0.25%; glutamic acid, 0.25%; lysine, 0.35%; and, in addition, arginine. The phenyl group contained in sericin cannot be recognised among the products of ozonisation.

Action of ozone on resins.—A fundamental difference exists between the ozonides of caoutchouc and dammar resin, since the latter is insoluble in carbon tetrachloride and not explosive. Decomposition with water leads to the formation of only a small quantity of acid, the main substance being a solid product, insoluble in water. Since other resins behave similarly to dammar resin, it is possible to establish the presence of resins in rubber by ozonisation in carbon tetrachloride solution, and the operation may be made quantitative, since the resin is quantitatively converted into the ozonide. The ozonide obtained by direct solution and ozonisation of dammar resin was not uniform, and the resin was therefore subjected to a preliminary treatment with acetic acid and precipitation with water. All the resins investigated yielded solid ozonides, the melting points of which lay between 53° and 81° C. The solubility of the ozonides was less than that of the resins; they are very sparingly soluble in light petroleum, slightly so in carbon tetrachloride, and yield clear solutions in alcohol, ethyl acetate, acetone, and acetic acid. The cleavage products are almost insoluble in light petroleum, slightly soluble in carbon tetrachloride, soluble in alcohol, ethyl acetate, acetone, and acetic acid, and, for the most part, in chloroform. A definite phytosterol- or isocholesterol-reaction is not given by the resins, ozonides, or their cleavage products. The iodine values of the ozonides, cleavage products, and resins are 126—285, 112—238, and 5—152, respectively. The ozonides have C = 47—61%; H = 6—11%; the cleavage products, C = 60.8—69%; H = 8—10%. The resins may be classified in the following groups: (i.) Dammar, mastic, sandarac; (ii.) brown and pale dammar copal, recent and fossil kauri copal; (iii.) rubber resin and guttapercha resin; (iv.) French colophonium, American resin, Mark B. elemi, and galipot. The solubilities of dammar, mastic, and sandarac are very different, those of their ozonides and cleavage products closely similar. From 82 to 83% of dammar resin is soluble in acetic acid; the residue after solution in light petroleum and precipitation with acetic acid, forms a white, amorphous mass, m. pt. 211° C., which probably consists of a hydrocarbon, $(C_{10}H_{16})_{15}$. The solubilities of the resins, ozonides, and cleavage products of the two dammar copals are approximately the same, and this is also true for the kauri copals. The melting points of the ozonides are 64° and 68° , 53° and 51° C. respectively; and of the resins, 154° and 158° , 92° and 119° C. respectively. Acid values, 198 and 201, 131 and 126 respectively. The solu-

bilities of the resins, ozonides, and cleavage products of the members of the third group show almost exact agreement. Melting points of ozonides, 63 and 70° ; of cleavage products, 92° and 87° C. The resins, ozonides, and cleavage products of group IV, also show marked analogies with respect to solubility, etc.

Potassium persulphate as a reagent in organic chemistry. R. L. Datta and J. N. Sen, J. Amer. Chem. Soc., 1917, 39, 747—750.

QUINOL (hydroquinone) is oxidised by neutral potassium persulphate, in the cold, with the formation of quinhydrone; aniline gives a good yield of Aniline Black, and *o*-toluidine is oxidised quantitatively to *o*-Toluidine Black. Acetanilide, when heated for some time with concentrated potassium persulphate solution, yields quinone, and acetic acid is liberated; benzanilide gives a small quantity of quinone after 24 hours' contact with persulphate and in this case benzoic acid is set free. Acetamide, propionamide, and butyramide are hydrolysed when boiled with potassium persulphate solution, the corresponding acids being formed. Allyl alcohol is readily oxidised by persulphate, the chief product being acrolein.—W. P. S.

Methyl salicylate: Method for the examination of —, A. R. Albright, J. Amer. Chem. Soc., 1917, 39, 820—825.

THE following method is described for the detection of small quantities of such substances as phenol, *p*-hydroxybenzoic acid, etc., in methyl salicylate; it depends on the fact that in a mixture of two substances having different refractive indices, one of the substances, if isometric, may be rendered practically invisible by immersing the mixture in a liquid having the same refractive index as that substance, whilst the other substance will stand out in more or less sharp relief. In the case of methyl salicylate, the sample is treated with an excess of benzoyl chloride, the mixture is agitated thoroughly and rendered alkaline from time to time with dilute potassium hydroxide solution until the reaction is complete. The salicylate and all phenolic substances present are thus converted into the same crystalline derivatives (benzoates). The resulting crystalline precipitate is collected, washed with water, dried, and recrystallised from warm alcohol. The crystals thus obtained are then mounted in a solution having a refractive index equal to that of benzoyl methyl salicylate (1.658); the mounting solution used is an aqueous solution of mercuric potassium iodide diluted or concentrated until it has the required refractive index. If the slide is now examined under the microscope, the benzoyl methyl salicylate tends to become invisible, leaving the other compounds, if present, in clear view. Using this method, the author has detected the presence of phenol in both natural and synthetic wintergreen and sweet birch oils; methyl *p*-hydroxybenzoate was also found in synthetic wintergreen oil.—W. P. S.

Butyric acid in biological products: Separation and determination of —, I. K. Phelps and H. E. Palmer, J. Biol. Chem., 1917, 29, 199—205.

THE process described depends on the insolubility of quinine formate and quinine acetate, and on the solubility of quinine butyrate in carbon tetrachloride. Briefly, the solution containing the three acids is neutralised with barium hydroxide solution, a quantity of quinine sulphate sufficient to precipitate the barium is added, the barium sulphate is separated by filtration, and the filtrate is evaporated under reduced pressure; the residue obtained is then extracted with carbon tetrachloride and the quinine butyrate recovered by

evaporating the solvent. From 89.7 to 100.5% of the butyric acid present is found by the process. The solubilities of quinine butyrate and quinine propionate are so nearly alike that only a partial separation of these two salts can be effected, but the propionate may be separated readily from the formate. The m. pts. and solubilities of the quinine salts mentioned are as follows:—

	M. pt. °C.	Solubility in carbon tetrachloride.
Quinine formate.....	110.0—113.0	1 in 16,000
„ acetate.....	124.0—126.0	1 in 2,000
„ propionate ..	110.5—111.0	1 in 450
„ butyrate.....	77.5	1 in 25
„ sulphate.....	214.0	1 in 40,000

—W. P. S.

Volatile fatty acids: The Duclaux method for the determination of—F. W. Upson, H. M. Plum, and J. E. Schott. *J. Amer. Chem. Soc.*, 1917, **39**, 731—742. (See also this J., 1917, 236, 519.)

CRITICAL examination of this method showed that unavoidable variations in experimental results are sufficient to render it untrustworthy. When more than two acids are present in a mixture, the results may be calculated equally well in terms of one, two, three, or more acids. Small amounts of acids may be distributed between the acids next higher and lower in the series. The method is considered to be unsound theoretically, and not suitable for determining the composition of unknown mixtures of fatty acids.—W. P. S.

Volatile fatty acids: The Duclaux method for—A. R. Lamb. *J. Amer. Chem. Soc.*, 1917, **39**, 746—747.

WHEN applied to pure formic, acetic, and propionic acids, this method yielded reliable results, provided that the experimental conditions were kept as uniform as possible. An electric hot plate was used as the source of heat, the 200 c.c. short-necked distillation flask was connected by a short bent tube to the condenser, and the flask was surrounded by an asbestos jacket. The water used was free from carbon dioxide, but it was found necessary to apply corrections for the carbon dioxide absorbed during the distillation. In the author's opinion, it is impracticable to attempt to determine more than two or three acids in the same mixture, and he considers that the unsatisfactory results obtained by Upson, Plum, and Schott (see preceding abstract) were due to impurities in the acids used, and to avoidable experimental variations.—W. P. S.

[Organic] acids: Identification of—H. J. A. Lyman and E. E. Reid. *J. Amer. Chem. Soc.*, 1917, **39**, 701—711.

IN addition to *p*-nitrobenzyl bromide (this J., 1917, 236), the chloride and iodide may also be used in the preparation of *p*-nitrobenzyl esters. The results suggest that it may be preferable to use the iodide instead of the bromide for dibasic acids.

—F. W. A.

Aldehydes: Identification of aliphatic—C. Harries and K. Oppenheim. *Chem. Zentr.*, 1916, ii., 991. *J. Chem. Soc.*, 1917, **112**, i., 210—211.

THE general reactions for aldehydes have been examined for a series of aliphatic aldehydes. It has been found that the semicarbazones of the lower aldehydes can only be induced to crystallise with great difficulty, whereas the higher aldehydes immediately yield crystalline products. Conversely, the nitrophenylhydrazones of the higher aldehydes are oily, those of the lower members

being crystalline. All the aldehydes investigated gave good results with diphenylmethanedimethyldihydrazine. Unsatisfactory results were obtained in attempting to apply Angeli's reaction (action of benzenesulphohydroxamic acid and conversion of the hydroxamic acids formed into their copper salts) to the exact characterisation of aldehydes. The physical and chemical characters of a number of aliphatic aldehydes and their derivatives are given.

Catalytic hydrogenation of organic compounds by base metals at ordinary temperatures. The removal of halogen from organic halogen derivatives. C. Kelber. *Ber.*, 1917, **50**, 305—310. (See this J., 1916, 382, 1130.)

PALLADIUM has been used for the displacement of halogens from organic compounds, and it has been found that the reaction in presence of palladised calcium carbonate proceeds so completely that the hydrogenation process may be used as a quantitative method for the determination of halogens. Equally satisfactory results may be obtained with nickel catalysts and in this case it is not necessary to recover the catalyst. A special shaking-tube has been designed for the use of this method for analytical purposes. This vessel is easily filled with the catalyst and the halogen derivative can be added subsequently; any contact of the liquid and catalyst with rubber connections is avoided and the product of the reaction can be quantitatively removed. The catalyst is prepared by heating basic nickel carbonate in a current of hydrogen at 310°—320° C., cooling, and passing a current of carbon dioxide over the material. The catalyst may be kept for a long time in closed vessels. For each determination, 3 grms. of the catalyst is placed in the reaction tube, shaken with water or dilute alcohol and 0.5—1.0 gm. of alkali hydroxide in presence of hydrogen until no more of the gas is absorbed, and the substance to be analysed is then sucked in and the funnel rinsed. Shaking is continued for some time after the reaction with the hydrogen is complete, the nickel is filtered off and washed, and the halogen in the liquid determined either gravimetrically or by titration. In the case of amino compounds or compounds which form precipitates with silver, the organic by-products should be shaken out with ether before making the halogen determination.—J. F. B.

Organo-metallic arsenic compounds; Activation of the therapeutic actions of quinine and mercury by—A. Gautier. *Comptes rend.*, 1917, **164**, 590—592.

THE efficacy of adding organo-metallic arsenic compounds, in particular of sodium dimethyl arsinate, to quinine in the treatment of malaria, as outlined by the author several years ago, has been confirmed recently by Ravaut and Kerdrel, who used injections of arsenol-enzyme supplemented by the usual dose of quinine in the treatment of the disease in Algeria. The subcutaneous injection of very small amounts of quinine and not more than 5—10 grms. of sodium dimethylarsinate, 8—10 hours before a probable attack, is advised; and the action of this specific in promoting the activity of the phagocytes has been verified experimentally. The association of organically combined arsenic with mercury has been equally successful as a remedy for syphilis.—E. H. T.

Mercuric salicylate and its isomers; Determination of mercury in basic—H. Lajoux. *J. Pharm. Chim.*, 1917, **15**, 241—246.

THE gravimetric determination of mercury in these complex salts (see this J., 1915, 733) is carried out by dissolving about 0.25 gm. of the salt and 1—1.5 gm. of potassium cyanide in 25 c.c.

of water. The solution is boiled, saturated with hydrochloric acid, diluted to 150 c.c., and then saturated with hydrogen sulphide. The resulting precipitate is weighed on a tared filter paper. For volumetric determination of the mercury, it is necessary first to destroy the organic complex and this, though possible, is tedious. If about 0.2 gm. of the salt is dissolved in 10 c.c. of *N*/10 potassium cyanide, the solution, after adding 10 c.c. of ammonia and about 1 c.c. of *N*/10 potassium iodide, may be titrated with *N*/10 silver nitrate. This leads, however, to results which show that only half the mercury has reacted with the potassium cyanide. If the result is multiplied by 2 the method is quite as satisfactory for determination of mercury not only in the salicylate but also in the *m*- and *p*-hydroxybenzoates. The commercial salt rarely contains more than 57% of mercury, while the formula requires 59.52%.—W. H. P.

Colloids; Protective—. *Cydonia* [quince] seed as protective colloid. Colloidal silver, gold, mercury, and platinum. A. Gutbier and A. Wagner. *Kolloid Zeits.*, 1916, 19, 280—302. *J. Chem. Soc.*, 1917, 112, ii., 168—169.

THE action of quince seed extract as a protective colloid has been examined in experiments with silver sols prepared by the reduction of silver nitrate by hydrazine hydrate in presence of the organic colloid. By dialysing the resulting colloidal silver solution and evaporating at low temperature or precipitating by the addition of alcohol, solid substances have been obtained containing about 20% of silver, which dissolve completely in water. Reversible colloids of the same kind were also obtained by the action of sunlight on silver nitrate solutions in presence of the quince seed extract. The coagulation of these protected silver sols by the action of various electrolytes has been examined, and the results indicate that the coagulating power diminishes in the order: sulphuric acid, sodium chloride, sodium carbonate, sodium hydroxide. Solid substances which contain up to 50% of gold and are completely soluble in water, may be obtained by the reduction of gold chloride by hydrazine hydrate in presence of quince seed extract. The protective action of the organic colloid on the gold sols is very pronounced. The protective action of quince seed extract on colloidal solutions of mercury prepared by the action of hydrazine hydrate on mercuric chloride is not very marked. If, however, sodium hydrosulphite is used as the reducing agent, much more stable solutions are obtained, and by dialysing and evaporating or precipitating with alcohol, solid colloids containing up to about 20% of metallic mercury have been prepared which are partly soluble in water. Platinum sols, prepared by the reducing action of hydrazine hydrate on platinum chloride in presence of quince seed extract, yield, on dialysing and evaporating or precipitating by the addition of alcohol, solid colloidal substances which contain as much as 25% of platinum. These colloids are readily soluble in warm water. As in the case of silver, gold, and mercury, the protective action of quince seed extract on colloidal platinum is strongly marked.

PATENTS.

Ether: Process and apparatus for the continuous production of—. E. Barbet et Fils et Cie., Paris. Eng. Pat. 100,406, May 2, 1916. (Appl. No. 6289 of 1916.) Under Int. Conv., May 5, 1915.

IN a continuous process for the production of ether by treating alcohol with sulphuric acid, the acid and alcohol are kept in contact until the alcohol is entirely absorbed, and the ethylsulphuric acid so formed is partially decomposed by heat in a separate part of the apparatus. The ether set free is collected, and the acid is brought into contact with a fresh supply of alcohol. Apparatus for carrying out the process consists of a plate tower down which the acid trickles against an ascending stream of alcohol previously vaporised in a tubular heater heated by steam. From the bottom of the tower, the ethylsulphuric acid passes to a "tubular emulsifying apparatus," where it ascends lead pipes surrounded by steam jackets. The bubbles of ether vapour emulsify the acid liquid and are led off from the top of the emulsifier, while the liquid partially freed from ether is returned to the plate tower. The latter may be replaced by a cylinder packed with suitable material, and the emulsifier may be placed above the cylinder in the interior of a large cylindrical boiler, so that the acid leaving the top of the emulsifier passes down the peripheral space, and enters again at the bottom of the packed cylinder with the fresh alcohol.—F. Sp.

Alcohols [fuel oil substitute]: Manufacture of— [from gasoline]. B. T. Brooks and H. Essex, Assignors to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,221,667, Apr. 3, 1917. Date of appl., Mar. 22, 1916.

HIGH-BOILING monohydric alcohols are produced by heating the corresponding chlorinated hydrocarbons, e.g., monochlorinated gasoline, with methyl alcohol and a formate under pressure at 140° C. to 190° C.—F. Sp.

Ethylene: Manufacture of— from acetylene. W. Traube, Berlin. Ger. Pat. 295,976, Nov. 22, 1914. Addition to Ger. Pat. 287,565 (see this J., 1916, 112).

THE process described in the principal patent is modified by using less than the theoretical amount of chromous salt, and regenerating it with reducing agents from the chromic salt produced. *Example.*—4 parts of crystalline chromic chloride, 20 parts of 25% hydrochloric acid, and 4 parts of zinc are shaken with 0.4 part by weight of acetylene under pressure. Ethylene and hydrogen are produced, and can be separated in the usual manner. Other chromium salts may be employed, and the concentration of the hydrochloric acid may be diminished.—F. Sp.

Ketones: Preparation of—. G. Schicht A.-G., and A. Grün, Aussig, Ger. Pat. 295,657, Sept. 8, 1914. Under Int. Conv., Sept. 20, 1913.

KETONES are produced by heating monocarboxylic acids of b. pt. above 300° C., in the liquid state, to temperatures not greatly exceeding 300° C., with small quantities of ketone-producing catalysts, e.g., finely divided metals, oxides, silicates, or silicic acid. Mixtures of catalysts, or catalysts deposited on finely divided carriers, or on filtering material, may be employed. In consequence of the relatively low temperature of the reaction and the absence of energetic reagents, the yield is practically quantitative. Stearic acid yields stearone, (C₁₇H₃₃)₂CO, m. pt. 87° C. Commercial

stearine of m. pt. 54° C. yields a mixture of stearone, palmitone, and stearopalmitone melting at 75° C.—F. Sp.

Ethyl triacetylglutamate: Process of making—K. Zimmermann, Elberfeld, Germany, Assignor to Synthetic Patents Co., New York. U.S. Pat. 1,222,315, Apr. 10, 1917. Date of appl., Jan. 5, 1911. SEE Ger. Pat. 279,958 of 1913; this J., 1915, 452.

XXII.—EXPLOSIVES; MATCHES.

Azides: Sensitiveness of—L. Wöhler and F. Martin. Z. angew. Chem., 1917, 30, 33—39.

VARYING definite weights, up to 0.02 gram, of different azides, in a micro-crystalline form, were compressed to a constant degree in the form of pellets. A steel cylinder insulated on the outside with thick asbestos was heated in a bath of Wood's metal. After the temperature, which was measured directly at the base of the cylinder, had become constant, the pellet was admitted through an opening in the asbestos lid and the time required for detonation noticed. Beginning with 0.005 gram, of the substance, the temperature necessary to cause detonation after a given interval fell in every case with increasing quantity of material, until with from 0.01 to 0.02 gram, a limiting value was reached above which the detonation temperature was independent of the mass of the material. The development of the explosion wave from a comparatively slow reaction requires a definite interval which becomes shorter with increasing temperature and with the constant of the reaction velocity. Conversely, with a shorter period of heating, a higher temperature is necessary to initiate detonation than with a long period, as has been shown in the ignition of methane-air mixtures. With a small quantity of the azide, complete decomposition by slow chemical change might follow at the temperature employed, whereas at a higher temperature or with a larger mass at the lower temperature the decomposition would lead to detonation. The fact that the limiting temperature is already reached with a weight of 0.01 gram, in the case of azides indicates a very high speed in the velocity of the decomposition which leads to detonation. With mercury fulminate, the detonation temperature did not fall so soon to a constant value with increasing mass, indicating that in this case the initial decomposition takes place more slowly and is accompanied by a larger loss through slow chemical change. With azides and fulminates of the different metals, the following values, arranged in order of sensitiveness, were obtained as the temperatures (°C.) at which 0.02 gram, of the substance detonated after an interval of 5 seconds. Azides: cobalt, 118°; barium, 152°; calcium, 158°; strontium, 169°; copper, 174°; nickel, 200°; manganese, 205°; lithium, 245°;

mercury, 281°; zinc, 289°; cadmium, 291°; silver, 297°; lead, 327°; thallium, 329°. Fulminates: thallium, 120°; silver, 170°; copper, 205°; mercury, 215°; cadmium, 215°; sodium, 215°; potassium, 225°. The temperatures of detonation are obviously not determined by the heat of decomposition as this is greatest in the case of the azides of silver, cadmium, and lead. The azides of metals of low atomic weight have lower temperatures of detonation than those of high atomic weight, in accordance with the view that the heavier molecule needs a higher temperature to acquire the velocity necessary for detonation. Differences were also observed in the manner of decomposition, from lithium azide, which gave a very violent detonation, to the azides of sodium, potassium, and thallium, which exploded without developing true detonation. More uniformity is shown with the fulminates, which, with the exception of thallium, have all detonating temperatures in the neighbourhood of 200° C. The hygroscopicity of the azides of metals of low atomic weight was found to be much higher than with those of high atomic weight. Sensitiveness to shock was measured by the falling weight method. The compound, in amounts varying from 0.01 to 0.05 gram, was compressed in a brass cap case of definite cross-section and covered with a disc of copper or tin, over which was placed a hardened steel block which received the impact of the falling weight. With the exception of the azides of strontium and barium, which only exploded with production of flame, and the azides of lithium, sodium, and potassium, which could not be made to explode at all by percussion, the compounds examined all detonated, violently on receiving sufficient impact. A very large influence was in most cases found to be exerted by the thickness of the layer. The sensitiveness of the azides of silver, lead, and mercury increased with the thickness of the layer, that of cadmium was almost constant, those of copper, manganese, zinc, and thallium diminished in sensitiveness with increasing thickness, and those of nickel, cobalt, calcium, barium, and strontium increased to a maximum value with 0.02 gram, and then the sensitiveness diminished. Apart from this large influence of the thickness, which gives a misleading high figure of insensitiveness in the case of thick layers of the azides of copper, nickel, cobalt, and barium, a general parallelism was observed between the sensitiveness to heat and to percussion, and as with the temperature of detonation, no relation was apparent between sensitiveness to percussion and the heat of decomposition. The sensitiveness to percussion of thin layers of the azides was found to be a measure also of their responsiveness to friction, which determines the instability of the material in filling caps and during compression and shaking. In this respect, as shown in the percussion measurements, the azides of copper, nickel, and cobalt are the most unstable, and those of silver, cadmium, zinc, and thallium much more stable. The sensitiveness of thin layers of copper azide is encountered in copper detonator tubes. The increased sensitiveness of thick layers of lead and mercury azides accords with the property shown by large crystals of spontaneous detonation. The instability of mixtures of crystalline and liquid nitroglycerin may be due to an analogous effect of the influence of the thickness of the layers of liquid enclosed between the crystalline faces. Greater regularity was obtained in the measurements on percussion with fulminates, the sensitiveness being always greatest with the thinnest layers. The parallelism between temperature of detonation and sensitiveness to percussion is closer with fulminates than with azides. Thallium fulminate is the most easily detonated by heat and is the most sensitive to percussion.—J. N. P.

XXIII.—ANALYSIS.

Nephelometer-colorimeter; An improved —, P.
A. Kober. J. Biol. Chem., 1917, 29, 155–168.

In the instrument described, the usual rack and pinion movement for raising the cups or plungers is replaced by a screw movement, the scale is removable, and dark cloth curtains are not used. The glass plungers and the nephelometric and colorimetric cups are made in one piece without cemented joints, and have optically clear bottoms. A convenient support is provided for keeping the eye steady and always at the same point. The lamp house has adjustable reflectors so that the amounts of light reaching both sides of the colorimetric field may be equally adjusted.—W. P. S.

Colloid-chemical phenomenon as indicator in quantitative analysis. J. F. Sacher. Koll. Zeits., 1916, 19, 276–277. J. Chem. Soc., 1917, 112, ii., 180.

In the estimation of lead by titration with a solution of ammonium molybdate, the supernatant liquid is turbid so long as the reaction is incomplete, but this turbidity disappears suddenly at the end-point. The turbidity is due to colloidal lead molybdate, and the coagulation of this serves to indicate the end-point. In practice, the solution of lead, acidified with acetic acid, is heated at 70°–80° C., and the progress of the titration is determined by removing a drop of the solution and observing its optical condition. The end-point is independent of the quantity of acetic acid present, and the method is to be preferred to the older procedure in which tannin is used as indicator.

Thymolphthalein and naphtholphthalein [in the determination of true neutrality in waters]; New applications of —, including rapid methods for analysing limestone and ammonium salts. J. Moir. J. Chem., Met., and Min. Soc., S. Africa, 1917, 17, 129–132.

THE insensitiveness of thymolphthalein to traces of alkali, particularly at the boil, has been utilised in the determination of lime and magnesia in limestone: 0.5 to 0.75 grm. of sample, free from grit, is mixed with about 10 c.c. of 2 N hydrochloric acid, the mixture heated on the water-bath for 20 mins., the turbid liquid diluted to about 20 c.c., and titrated with N/2 caustic soda (free from carbonate) using a 0.02% methyl red solution in dilute alcohol as indicator: the combined acid-equivalent of the lime and magnesia is thus obtained. After diluting to 50 c.c. and raising to the boil for one minute, 3 c.c. of 1% thymolphthalein solution in 60–70% alcohol, and then sufficient N/2 caustic soda to give a dark blue solution are added, the mixture boiled for one minute to coagulate the precipitated magnesia, and the blue suspension titrated until yellow with N/2 hydrochloric acid; in this manner the magnesia content is determined, and the lime may be obtained by difference. A correction should be made in case an appreciable amount of phosphate is present. The results agree closely with those found by the ordinary method.

In analysing the ammonium salts of strong acids, the solution, previously neutralised to methyl red if necessary, is titrated at the boil with N/5 caustic soda in presence of a small quantity of a saturated

solution of thymolphthalein in 50% alcohol until the deep blue to green colour reappears and withstands boiling for 20 secs.

The true neutrality of water is determined by using as mixed indicators methyl red and α -naphtholphthalein, which are much more delicate than methyl orange and phenolphthalein, and will detect 0.1 part sulphuric acid and 0.2 part calcium hydroxide per 100,000. In presence of more than 0.4 part acid per 100,000, the colour is violet-rose; 0.2 part acid, salmon-orange; neutral, straw-yellow; 0.2 part alkali, citrine-green; over 0.4 part alkali, deep bluish-green. Neutral red, rosolic acid, or alizarin may be used in place of methyl red.—F. W. A.

Iodine; Titration of — with thiosulphate. R. Kempf. Z. angew. Chem., 1917, 30, 71–72.

In the titration of an iodine solution by thiosulphate in presence of free acid, a certain error arises by a reaction between the thiosulphate and the acid, as shown in the equation:

The reaction is made possible by the greater rate of diffusion of acid than of iodine into the layer of thiosulphate admitted to the solution. The sulphur dioxide formed neutralises subsequently two equivalents of iodine, whereas this quantity of iodine would react with two molecules of thiosulphate in the more rapid reaction producing tetrathionate. The reaction with the acid can be observed by the production of an opalescence due to sulphur, and can be minimised by avoiding a large excess of acid, by efficient stirring during the titration, and by running the thiosulphate from the burette slowly in drops. In the presence of alkali a still greater error is caused by the direct oxidation to sulphate brought about by iodine in an alkaline solution.—J. N. P.

Iodimetry; Differential —. II. Titration of chromic acid in the presence of ferric iron and the analysis of chromite. O. L. Barnebey. J. Amer. Chem. Soc., 1917, 39, 604–606. (See also this J., 1916, 358.)

THE reaction between potassium iodide and chromic acid proceeds to the exclusion of any effect from ferric iron in the presence of phosphoric acid, which converts the iron into a soluble acid phosphate. It is necessary to adjust the concentration of the phosphoric acid, as if the acid used is too strong, ferric iron reacts with the iodide, and if too weak the liberation of iodine by the chromic acid is too slow. When allowing three minutes for the reaction, the minimum acidity required for a concentration of iodide equal to N/10, was found to be 2.5 N. The estimation of chromium in presence of iron in an aqueous solution is conducted by making just alkaline with sodium hydroxide, adding solid sodium peroxide in slight excess, and boiling for a few minutes to decompose the excess of sodium peroxide. In the analysis of chromite, the sample is fused with sodium peroxide in a porcelain or silver crucible, extracted with water, and the excess of peroxide removed by boiling. In either case phosphoric acid is then added until the iron phosphate is completely dissolved and the solution has an acidity of about 3 N. 10 c.c. of N/1 iodide is then added for each 100 c.c. of solution and the liberated iodine titrated with standardised thiosulphate. Comparative determinations made in presence of, and after removal of, the iron by filtration gave results in close agreement.—J. N. P.

Iodimetry; Differential —. III. Determination of the available oxygen in soluble and precipitated oxidised forms of manganese. O. L. Barnebey and W. C. Hawes. J. Amer. Chem. Soc., 1917, 39, 607–610.

USE is made of the inappreciable rate of reaction

of ferric iron with iodide when in dilute phosphoric acid solution as a means of estimating manganese, through the liberation of iodine from an iodide by the oxidised manganese salt. It was found that potassium permanganate in presence of iron can be titrated accurately by the liberation of iodine in phosphoric acid solution. Samples of manganese dioxide in the form of Weldon mud, and as obtained by the reduction of potassium permanganate, and by precipitation from manganese salts by hydrogen peroxide, chlorate, and hypochlorite, were dried at 105° C., and weighed samples treated with 10 c.c. of $N/1$ iodide and 10 c.c. of 2 N phosphoric acid. The solutions were agitated gently until the reaction was complete and then titrated with thiosulphate, with results which agreed closely with the estimations made by Bunsen's distillation method. A direct estimation can in some cases be made with natural manganese ores by treating the finely ground material with 10 c.c. of $N/1$ iodide and 10 c.c. of 2 N phosphoric acid, then diluting to 100 c.c., allowing to react for 10 minutes, and titrating. Some samples of pyrolusite which contained a considerable amount of iron oxide were found, however, to be attacked with difficulty and could not be analysed successfully by this method.

—J. N. P.

Ammonia; Applications of a new reagent for the separation of —. 1. *Colorimetric determination of ammonia in urine.* O. Folin and R. D. Bell. *J. Biol. Chem.*, 1917, 29, 329–335.

THE reagent used is an artificial sodium zeolite, known commercially as permutit, in powder of 60–80-mesh fineness. About 2 grms. of the powder is placed in a 200 c.c. flask, 5 c.c. of water added, and then 1 or 2 c.c. of urine or 5 c.c. of diluted urine. The flask is rinsed down with a little water and shaken gently for 5 mins. The powder is then washed down from the sides of the flask with 25–40 c.c. of water, allowed to settle, and the liquid decanted. After another washing and decantation, a little water is added to the flask and 5 c.c. of caustic soda (10%), the contents are mixed and water is added until the flask is three-quarters full; it is then shaken and 10 c.c. of Nessler solution is added and mixed. After standing 10 mins., the contents are made up to the mark with water, and the colour compared with that given by a standard solution of ammonia treated with 5 c.c. of caustic soda in the same way. The reagent may be recovered and used over again, after washing with dilute acetic acid and drying.—J. H. J.

XXIV.—MISCELLANEOUS ABSTRACTS.

Mellitic acid; The occurrence of —. E. O. von Lippmann. *Ber.*, 1917, 50, 236–238.

THE presence of mellitic acid has previously been recorded in a black, humus-like deposit formed by the gradual decomposition of pure sugar solutions under factory conditions (this J., 1895, 375). A similar instance has again been observed in the case of a very loose, nearly dry, coal-like, lustrous deposit found on dismantling an old copper pipe. Extraction of the powdered deposit with alcohol yielded crystals of fine white needles of mellitic acid, melting at 200° C. with decomposition. The acid was characterised by its crystalline barium salt, insoluble in water and alcohol, occurring as fine needles having the formula $C_{12}O_{12}Ba_3 + 3H_2O$. Another case of the formation of mellitic acid was observed in a heap of ordinary lignite (brown coal) on which a barrow-load of alumina sludge had accidentally been overturned two years previously. Under the sludge in the middle of the coal was a board which had been broken so as to form an angle and in the hollow space below the board was found a bunch of yellow crystals, the size of nuts, which were identified as "honey-stone," $C_{12}O_{12}Al_2 + 18H_2O$.—J. F. B.

Official Notices.

ANNUAL GENERAL MEETING, 1917.

In accordance with the provisions of By-law 64, notice is hereby given that the Annual General Meeting will be held in The University Buildings, Edmund Street, Birmingham, at 10.30 a.m. on Wednesday, July 18th, 1917. A programme of the proceedings is inserted loose in this issue.

In accordance with the provisions of By-law 24, those members whose names are printed in *italics* in the List of Council will retire from their respective offices at the forthcoming Annual Meeting.

Prof. Henry Louis has been nominated to the office of President under By-law 20; Dr. Charles Carpenter has been nominated Vice-President under By-law 20; Mr. John Gray, Mr. A. R. Ling, Prof. R. F. Ruttan, and Mr. J. T. Wood have been nominated Vice-Presidents under By-law 21.

Mr. A. G. Bloxam, Mr. W. J. Rees, Mr. Edwin Thompson, and Prof. James Walker have been nominated to fill the four vacancies among Ordinary Members of Council, under By-law 25. No ballot will be required.

J. P. LONGSTAFF,
Secretary.

REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY.

The first volume of these reports is now ready. As the issue is strictly limited, those who desire to obtain copies are advised to apply for them without delay. The price is 3s. to members and 5/6 to non-members, including postage.

IMPERIAL MINERAL RESOURCES BUREAU.

By direction of the War Cabinet, the Minister of Munitions has made arrangements for the appointment of an inter-departmental Committee to prepare a scheme for the establishment in London of an Imperial Mineral Resources Bureau to collect information in regard to the mineral resources and metal requirements of the Empire, and to advise what action, if any, may appear desirable to enable such resources to be developed and made available to meet requirements.

The Committee consists of the following gentlemen:—Sir James Stevenson, Bart. (Chairman), Mr. C. L. Budd, Sir A. Duckham, K.C.B., Professor W. R. Dunstan, C.M.G., Mr. C. W. Fielding, Mr. J. E. N. Green, Right Hon. Lord Islington, G.C.M.G., Mr. L. J. Kershaw, C.I.E., Sir T. Mackenzie, K.C.M.G., Hon. Sir G. H. Perley, K.C.M.G., Mr. W. S. Robinson, Right Hon. W. P. Schreiner, C.M.G., K.C. The Secretary to the Committee is Mr. Oswald C. Allen, and all communications on the subject should be addressed to him at the Ministry of Munitions, Whitehall Place, S.W.1.

INTERPRETATIONS OF EXPORT PROHIBITIONS.

The following interpretations of prohibitions of export from the United Kingdom have been issued by the Director of the War Trade Department, 4, Central Buildings, Westminster, S.W.1 (P.=Prohibited, N.P.=Not prohibited to any port or destination except in Sweden):—

Alcohol in which microscopic slides or laboratory specimens are packed, N.P. Aniline dye, manufactured articles containing not more than 3% of, as the only prohibited ingredient, N.P. Argols, crude (used in the making of tartaric acid), P. Blast-furnace tar, P. Bradford sewer grease, P. Capsicum essence made from chillie fruit, P. Carboic acid and formaldehyde B. & W. mixture known as "liquid resin," P. Carboic acid in preparations containing not more than 1% extractable crystals as the only prohibited ingredient, N.P. Carbon brushes, P. Cardamoms, P. Chloroform, P. Clay, diatomite, N.P. Copper scale (or copper pickle dust), P. Cutch, P. Ether, ozonic, P. Firebricks and fireclay forming integral parts of manufactured goods not otherwise prohibited, N.P. Flint, powdered, N.P. German silver, P. Glycerin in toilet and other preparations containing not more than 1% as the only prohibited ingredient, N.P. Hard lead, P. Incandescent mantle rings (magnesia), P. Lamp black, N.P. Manganese dioxide or black oxide of manganese, P. Naphtha, wood, P. Nickel silver, P. Perfumed spirits, N.P. Pyrometers, P. Rectified spirits of wine, P. Tartar emetic, P. Terebene, P. Tin foil, P. Umber (a coloured earth), N.P. Vaseline P. Vulcanising compound, composed of rubber, litharge, and sulphur, P.

EXPORT PROHIBITIONS.

The Supplement to the "Board of Trade Journal" of 31st May contains complete lists of articles which, according to the latest information received by the Board of Trade, are prohibited to be exported from Denmark, France (including Algeria), Italy, Japan, and the Netherlands. The Supplement also contains the list of articles (complete to date) which are prohibited to be exported from the United Kingdom.

EXPORTS TO SWITZERLAND.

The May 31st issue of the "Board of Trade Journal" contains, on pages 179—196, a list, corrected to May 19th, of articles in respect of which licences for export to Switzerland are only granted if the goods are consigned to the Société Suisse de Surveillance Economique, showing also those which are allowed to benefit under the special system for small parcels.

NORWAY: PROHIBITED EXPORTS.

The exportation of the following articles from Norway has been prohibited:—Calcium chloride, Carboic acid, Coal pitch, Creosol, crude, Dégras, Formalin, Hydrochloric acid, Sodium sulphate, calcined and crystallised.

SWEDEN: PROHIBITED EXPORTS.

The exportation of the following articles from Sweden has been prohibited as from the 20th May:—Asphalt lac and "zapon" lac, Asphalt, manufactures of, not specially mentioned in the Swedish Customs Tariff, with or without admixture of sand, gravel, textile waste or the like, and even if combined with other material, Carborundum (carbide of silicon) and other carbides not specially mentioned in the Swedish Customs Tariff, Celluloid, celloidin, galalith, ambroin, eburin and other

similar artificial plastic materials, not specially mentioned in the Swedish Customs Tariff. Cement, Portland, ordinary grey, white, or coloured, ground or not, and slag cement, trass and other varieties of cement used for building purposes. Chrome acetate. Disinfectants, not specially mentioned in the Swedish Customs Tariff, containing soap or soft soap, such as lysol and creolin. Formalin in aqueous solution. Formic acid and lactic acid. Fusel oil. Insulating compositions (for protection against heat or cold), dry or liquid, consisting of two or more mineral substances, such as asbestos, kieselsuhr, asphalt clay, or cement, with or without admixture of cotton fibres, animal hair or the like, or consisting of one mineral material with admixture of such materials; also manufactures of the compositions specified, such as slabs, segments, and other shaped pieces. Mercury and mercury alloys (amalgams). Oxalic acid, and oxalates of potassium, sodium, and ammonium. Paints, even if dry, prepared with base other than oil (such as with albumen or casein), and colours not specially mentioned in the Swedish Customs Tariff. Quillaia bark. Resin in lumps, or powdered, also turpentine and other natural balsams, including liquid resin, such as sulphate resin and crude pine and fir resin. Tar distillation products—benzol, carbolic acid, cresol, naphthalene, creosote oil, carbolineum, and the like, also carbolic lime. Tartar and seignette salts and other tartrates of potassium, sodium, and ammonium. Vegetable waxes (carnauba, palm, and other). Vulcanised fibre and other chemically prepared fibre board in plates or sheets (leaves). Vulcanised fibre in tubes or rods.

RESTRICTIONS ON DEALING IN SULPHURIC ACID.

The Minister of Munitions has issued an Order, under date 29th May, to the following effect:—

1. No person shall as on and from 11th June, 1917, until further notice, manufacture sulphuric acid except under a licence issued by or under the authority of the Minister of Munitions and in accordance with the terms and conditions of such licence as to the quantities to be manufactured or otherwise.

2. No person manufacturing sulphuric acid shall as on and from 11th June, until further notice, use during any one calendar month more than ten tons in all of 95% sulphuric acid (or its equivalent in acid of other strengths) for the purpose of all other manufactures, trades and businesses carried on by him except under and in accordance with the terms and conditions of a licence issued by or under the authority of the Minister of Munitions.

3. No person shall as on and from 30th May, until further notice, supply sulphuric acid (including waste sulphuric acid) to any person except under and in accordance with the terms and conditions of a licence issued by or under the authority of the Minister of Munitions. Provided that no licence shall be required to supply not more than 56 lb. of 95% sulphuric acid (or its equivalent in acid of other strengths) to any person during any one calendar month. And provided also that any sulphuric acid supplied

subsequently to the date of this Order, in pursuance of written directions or requests given or made by or on behalf of the Minister of Munitions previously to the date of this Order shall unless and until such written directions or requests are cancelled or withdrawn be deemed to have been supplied under a licence issued under the authority of the Minister of Munitions within the meaning of this Order.

4. As on and from 29th May until further notice, no manufacturer of sulphuric acid, or agent of such a manufacturer, shall charge or receive in payment for any sulphuric acid supplied by or through him a price exceeding the maximum price specified in the schedule to this Order for sulphuric acid of the description and strength supplied. Provided that the maximum prices specified in the schedule hereto shall not apply to—(a) Sulphuric acid supplied to persons outside the United Kingdom under export licences; (b) sulphuric acid manufactured outside the United Kingdom; (c) sulphuric acid made wholly from brimstone; (d) sulphuric acid specially purified for laboratory purposes.

5. All persons engaged in producing, manufacturing, selling, distributing or storing sulphuric acid (including waste acid), or in any manufacture, trade or business in which the same is used, shall make such returns with regard to their businesses as may from time to time be required by or under the authority of the Minister of Munitions.

6. For the purpose of this Order the expression sulphuric acid shall include sulphuric acid of all strengths up to 100% H_2SO_4 , but shall not include acid containing free SO_3 (commonly called oleum or fuming sulphuric acid).

NOTE.—All applications in reference to this Order (including applications for licences) should be addressed to the Director of Acid Supplies, Ministry of Munitions, Department of Explosives Supply, Storey's Gate, Westminster, S.W.1.

SCHEDULE.

Maximum prices for sulphuric acid.

1. *Weak acid, i.e., acid of all strengths up to and including 90% H_2SO_4 .*

Maximum price per ton.

Class A.	Arsenical acid	78s.
Class B.	Non-arsenical or de-arsenicated acid.	85s.

For acid of 140° Tw. at 60° F., with an increase or reduction of 5d. in respect of each complete degree Twaddell by which the specific gravity is more or less than 140° Tw. at 60° F.

For acid of 144° Tw. at 60° F., with an increase or reduction of 6d. in respect of each complete degree Twaddell by which the specific gravity is more or less than 144° Tw. at 60° F.

2. *Concentrated acid, i.e., acid of all strengths over 90% H_2SO_4 .*

Maximum price per ton.

Monohydrate (H_2SO_4) content of acid.	Class C.		Class D.	
	Arsenical acid.		De-arsenicated or non-arsenical acid.	
Over 90 and up to 91	£	s. d.	£	s. d.
.. 91 .. 92	5	3 0	5	13 0
.. 92 .. 93	5	9 0	5	19 0
.. 93 .. 93½	6	1 0	6	5 0
.. 93½ .. 94	6	4 0	6	11 0
.. 94 .. 94½	6	7 0	6	17 0
.. 94½ .. 95	6	10 0	7	0 0
.. 95 .. 95½	6	15 0	7	5 0
.. 95½ .. 96	7	0 0	7	10 0

Over 96 in both classes, an addition of 1s. per ton for each complete one-tenth of one per cent. of additional monohydrate.

Packages.

All the above maximum prices are for acid delivered into tank wagon, tank cart or tank barge at makers' works.

When the acid maker supplies the railway tank wagons he shall be entitled to make a further charge of not more than 5s. per ton for hire of such wagons. When the acid maker supplies the acid in his own drums he shall be entitled to make a further charge of not more than 10s. per ton for filling and hire of drums. When drums are supplied by the purchaser a charge of 2s. per ton may be made to cover the cost of filling. When the acid is supplied in the acid maker's own carboys he shall be entitled to make a further charge of £1 per ton for filling and hire of carboys. When carboys are supplied by the purchaser a charge of 5s. per ton may be made by the acid maker to cover the cost of filling.

Extra carriage.

In cases where a maker of sulphuric acid has, in order to supply his customers, to purchase supplies of acid from a third party, it will be permissible for him, in so far as this is a departure from his normal procedure, to charge to his customers any extra cost of carriage thereby incurred.

Birmingham Section.

Meeting held at White Horse Hotel, Birmingham, on Thursday, March 29th, 1917.

MR. HARRY SILVESTER IN THE CHAIR.

THE USE OF NITRE CAKE AS A SUBSTITUTE FOR SULPHURIC ACID IN THE PICKLING OF ANNEALED BRASS.

BY H. W. BROWNSDON, M.Sc., Ph.D.

Under present abnormal conditions, the quantity of sulphuric acid used for the pickling of annealed brass must run into several hundred tons per week. Difficulty in obtaining raw material and labour, coupled with the increased demand of sulphuric acid for other purposes, has resulted in an extended application of nitre cake solutions in place of dilute sulphuric acid for the pickling of annealed brass.

As a pickling agent, nitre cake solution is inferior to sulphuric acid and under certain conditions its use leads to very unsatisfactory results. For this reason, the subject of this communication is of more than passing interest to those who have to deal with the rapid pickling and cleaning of large quantities of annealed brass.

The two products controlling the success or otherwise of the process, are the nitre cake and the annealed brass.

Nitre cake is essentially crude acid sodium sulphate, and whilst the latter in the pure anhydrous state contains theoretically 40.8% of sulphuric acid, the free acid found in nitre cake may vary from 5 to 30%. It is evident that where difficulty may be experienced in obtaining satisfactory results with nitre cake poor in free acid, complete satisfaction may be given with better qualities, and in purchasing a by-product of this nature for pickling purposes a minimum content of free acid should be specified. In the Midlands there is no difficulty in obtaining nitre cake showing 25 to 28% of free acid calculated as sulphuric. Nitre cake invariably contains small quantities of free nitric acid which, however, from a pickling point of view are negligible.

For pickling, the nitre cake solution should be of such strength as to show 3 to 5% of sulphuric acid on titration, and for reasons which may be considered later, there is no advantage to be gained in using solutions of higher acid concentration.

Whilst nitre cake is a variable product, annealed brass from a pickling point of view may be even more so. According to the conditions of annealing, it may be clean, practically free from superficial oxides and of a brassy lustre, or it may be dirty, black in colour and badly stained through oxidation and contact with injurious furnace gases. Given clean work, nitre cake solutions replace dilute sulphuric acid quite efficiently, but with dirty work the difference is much more marked, and nitre cake solutions, even under the most favourable conditions, may fail to pickle the work satisfactorily. In the latter case the use of nitre cake in place of sulphuric acid becomes a serious handicap and deterrent to rapid production, especially when manufacture consists of a sequence of mechanical operations between each of which the product has to be annealed, pickled, and cleaned. It is little consolation for the manufacturer to know that his troubles lie in his annealing furnaces, for he cannot equip himself with furnaces of new type in order to overcome difficulties of pickling, and it is left to him to see that the nitre cake solution is used under the most favourable conditions possible for efficient pickling. Much may be done on the following lines in this direction.

(a) The nitre cake solution should be as hot as possible.

(b) Its acid content should be tested frequently and maintained at 3 to 5% by the addition of nitre cake.

(c) The hot annealed products may be quenched in water, whereby much scale is mechanically loosened and readily recovered prior to pickling.

(d) The hot annealed work may be placed direct into the nitre cake solution. The pickle can thus be maintained at a high temperature without auxiliary steam heating.

(e) Oxidising agents such as ferric salts, bichromates, or persulphates may be added to the pickle. Their addition stimulates the solvent action of the nitre cake solution, but their action is not constant and in many cases the price is prohibitive.

(f) Electrochemical aid might be sought by using a low voltage current, making the lead lining of the vat the cathode and the work to be pickled the anode.

(g) The movement of the work in the pickle or the agitation of the pickle during pickling.

The difficulties met with in the successful use of nitre cake solution can only be overcome in a satisfactory manner by, in the first instance, paying close attention to the conditions governing the annealing, so as to obtain the annealed brass as clean as possible, and secondly, by using the nitre cake solution under conditions which will most strongly stimulate its pickling activity.

The comparative sluggishness of nitre cake solution as compared with dilute sulphuric acid of equal acidity may be theorised upon in the light of the ionic dissociation of chemical substances when in aqueous solution. That the solvent power of an acid is reduced by the addition of a quantity of neutral salt of the same acid is a fact made use of in several analytical separations by precipitation.

It is quite likely, however, that the action of pickle is not simply solvent, as between oxide film and acid. In the case of annealed brass being immersed in an acid pickle, all the elements are present for electrochemical action, and the difference in potential arising between the metal and the oxides may produce minute local currents

which may aid or deter the solvent action of the pickle according to the nature of the free ions present in the pickle, which then becomes the electrolyte.

From the point of view of economy in future developments, at present ruling prices of £1 per ton for sulphuric acid and nitre cake at £1 per ton, there is not much to choose, but the economy of metal which would result from the more general use of muffles annealing bright or clean would be considerable, and if the use of nitre cake forces us to pay more attention to economical annealing conditions, it will have achieved indirectly some good purpose.

DISCUSSION.

Mr. F. H. ALCOCK said that nitre cake frequently contained considerable quantities of nitric acid, and it was not justifiable to consider the free acidity as due entirely to sulphuric acid. The use of an ammonium salt has been advocated to improve the working of the pickling material. He agreed that the higher the temperature the better the result, owing to the removal of the nitric acid.

Mr. E. KILBURN SCOTT said that the common method of dissolving the nitre cake was to throw the material into the "bosh," and to make the solution in a spare bosh. The importance of using steam in these boshes could scarcely be exaggerated, and yet the number of firms using steam was small. The agitation of the boshes was essential for work on tubes; there was a certain agitation when the tubes were lifted out and put back again, but continued agitation could be maintained by rockers. Much of the waste of metal and acid was due to men being engaged on piece work, and requiring a strong solution in the morning.

Mr. C. LEIGH agreed as to the utility of nitre cake, which, he said, was often condemned because the sulphate was not washed out sufficiently. The difficulty was that the picklers would not keep the boshes clean. His difficulty had been to get nitre cake containing sufficient sulphuric acid.

The CHAIRMAN said that nitre cake contained little acid: he had found never more than 17%, and as low as 5%. He had known it take half-an-hour to remove any trace of oxide from a piece of sheet steel. He could not understand why the large amount of sulphate of iron which was obtained could not be directly used for the manufacture of sulphuric acid. He agreed that the agitation of the bosh increased the efficiency of the pickle.

Dr. BROWNSDON, in reply, said that 25% of acid was obtained from nitre cake on titration. The oxidation products of brass were deceptive; zinc oxide predominated even in the presence of black scale. In spent pickle the zinc percentage was in higher ratio. An effective way of dealing with the cake was in tubs in the solid form.

MR. JOHN GRAY IN THE CHAIR.

APPLICATION OF THE GUTZEIT TEST TO WORKS' DETERMINATIONS OF ARSENIC.

BY C. HOLLINS, B.Sc.

The apparatus described below, which is a modification of that used by Bird (Chem. and

Drug., 1901, 600; see also Sanger and Black, this J., 1907, 1115), has been found very useful for determining the quality of dearsenicated vitriols. It is also applicable to estimation of arsenic in phosphates, phosphoric acid, and other substances containing only small quantities of arsenic.

As shown in the diagram, A is a wide-mouthed bottle of about 100 c.c. capacity, fitted with a two-holed rubber bung. B is a glass tube bent at right angles and stoppered by rubber tube and glass rod. B is used for clearing out the gas after an unfinished experiment. It also enables the washing apparatus to stand conveniently when the bung is removed from the bottle. B may be replaced by a small tap-funnel if desired.

The washing bulbs, C, D, and E, are blown on a piece of glass tubing 4—5 mm. internal diameter. The diameter of each is about 2 cm. C and D contain a little lead acetate solution (10—20%). E is tightly packed with glass wool, which is wetted with the lead acetate solution. The tube is constricted between bulbs, D and E, to facilitate the packing of E. A constriction at H produces regular bubbling. F, 10 cm. long, carries the mercuric chloride paper strip, which is supported by the constriction, G. G also serves to direct the flow of gas. The paper must be shielded from too bright daylight by a cardboard cover placed over F—a piece of thermometer case is convenient—or F may be painted black. F is inclined at about 45° to the vertical. This results in more satisfactory stains than a vertical tube and permits of a faster evolution of gas without undue lengthening of the stain. Apparently there is no advantage in making F horizontal.

Mercuric chloride paper. Thin Michallet drawing paper is cut into sheets of convenient size and soaked in water (in a photographic developing dish) until limp. The water is drained off and replaced by 1% mercuric chloride solution in which the paper is kept moving for half an hour. The sheets are then drained and dried in a steam oven separately. They must not be unduly exposed to bright daylight. When dry the sheets are cut into strips about 4½ in. long and of uniform width (2—3 mm.). The strips are kept in the dark in a test-tube fitted with a rubber bung. They are reliable for two or three months.

Standard stains:—A standard arsenic solution containing 0.001 mgrm. As_2O_3 per c.c. is used. (This may be made from N/10 sodium arsenite

by diluting 20·21 c.c. to 1 litre and further diluting 10 c.c. of this to 1 litre.)

In the bottle are placed x c.c. of standard arsenic solution, $40-x$ c.c. of water, and 2 c.c. of pure arsenic-free sulphuric acid. A strip of mercuric chloride paper is placed in position, 3—4 grms. of pure arsenic-free zinc added to the liquid, and the bung at once replaced. By the judicious admixture of a little zinc which has been previously used, the rate of evolution of the stream of gas may be kept regularly at 2—4 bubbles per second.

After half an hour the stain is complete. The standard is transferred to a bulb tube containing phosphorus pentoxide (kept in the bulb by a stopper of cotton wool), and the tube is sealed off. Convenient standard stains are those corresponding to 0·001, 0·002, 0·005, 0·010, 0·015, 0·020, 0·025, 0·030, 0·040 and 0·050 mgrm. As_2O_3 . The stains blacken quickly in direct sunlight and should be exposed as little as possible to daylight. With ordinary care a set of standard stains will be reliable for about three months. The sensitiveness of a new batch of paper must always be tested by preparing two or three standards from it.

Determination of arsenic in de-arsenicated vitriol. In the bottle are placed 40 c.c. of water, a measured volume of the vitriol (0·5 to 2 c.c.), and enough pure arsenic-free sulphuric acid to make up the total acid to 2 c.c. at 168° Tw. Three drops of stannous chloride solution (arsenic-free) are added to reduce arsenic compounds, the paper strip is placed in the tube, and 3—4 grms. arsenic-free zinc added as before. After half an hour the stain is compared with the standard stains, and its value estimated in micromilligrams As_2O_3 , and expressed as parts As_2O_3 per million of acid.

If by reason of too large a volume of lead acetate solution in the bulbs the paper strip becomes wet, the experiment is spoiled. The tube, F, should be dried when necessary by means of a screw of filter paper. Too vigorous reaction produces a long stain. The best stains are produced when the gas comes off at about 2 bubbles per second.

The most accurate results with 1% mercuric chloride paper are given by stains between 7 and 20 micromilligrams. The accuracy attained is within 5%. With stains of 35 or less there is no loss of arsenic hydride. This was proved by taking varying amounts of a de-arsenicated vitriol. The results with stains of 40, 32, 24, 16, and 8 micromilligrams were identical. In other experiments mercuric chloride paper was fastened across the top of tube, F, in addition to the strip in its usual position. No stain was visible at the top of the tube, even on development with concentrated hydrochloric acid. Under certain conditions of dilution appreciable quantities of hydrogen sulphide are produced during the reaction. The experiment is quite reliable, however, unless enough hydrogen sulphide is formed to blacken the glass wool.

The time occupied by a single determination is less than 35 minutes. With a dozen sets of apparatus twelve determinations are easily made in 45 to 50 minutes. On 1 c.c. of concentrated vitriol or two grams of other substances the range of the test is 0·3 to 27 parts per million.

A stain which is otherwise invisible may be developed by touching the paper with a drop of concentrated hydrochloric acid. A stain which is just visible on development represents about 0·05 micromilligram of As_2O_3 .

Many experiments have been made with paper of different qualities and weights. Thin filter paper can be made most sensitive but is less convenient to handle than the Michallet drawing paper. The sensitiveness is decreased by using a stronger solution of mercuric chloride. It does not increase on dilution beyond 0·5%.

Prepared with 1% solution is nearly three times as sensitive as that prepared with a saturated solution.

The apparatus is easily cleaned by rinsing under the tap. A little concentrated nitric acid removes all lead sulphide and sulphate, but all trace of nitric acid must afterwards be washed out with water. The lead acetate solution requires renewal after about a dozen experiments.

The method was primarily devised for works determinations on de-arsenicated vitriol and for this it has proved itself eminently satisfactory. It is quite applicable, however, to other substances, such as phosphates and phosphoric acid, containing small quantities of arsenic. The time necessary for completion of the stain varies for different substances.

The apparatus and also strips of mercuric chloride paper are supplied by Messrs. Towers of Widnes.

In conclusion I should like to express my thanks to the United Alkali Co. of Widnes, in whose laboratories most of my experiments have been performed, and to the Ministry of Munitions for permission to publish this paper.

*Meeting held at Bolbec Hall on Wednesday,
April 25th, 1917.*

MR. H. PEILE IN THE CHAIR.

FUSED SILICA.

BY DR. FRANK BOTTOMLEY.

Numerous attempts to fuse and work quartz or other forms of silica have been made during the last seventy years. In 1839 a French experimenter, Gaudin, fused quartz into a pasty condition with an oxy-hydrogen blowpipe, and similar experiments were also made about 1878 by another French worker, Gautier.

The first practical results were, however, obtained by Boys, who devised an ingenious method of making very fine filaments by shooting off lumps of silica from a softened quartz crystal by means of a crossbow; these filaments were employed in delicate electrical instruments, as for example for suspending the mirror in galvanometers. Other early workers in the field were Dufur and Le Chatelier and the firm of Schott and Genossen in Jena who exhibited a quartz lens in the Paris Exhibition of 1900. The experiments up to this date were, however, chiefly of academic interest.

In 1901 Shenstone read a paper before the Royal Institution, in London, giving the result of his experiments in working quartz by means of an oxy-hydrogen blowpipe, and gave details of a practical method of producing articles of fused quartz from rock crystal. Shenstone's method consisted in fusing a number of small fragments of crystal together to form a rough rod by means of an oxy-hydrogen blowpipe, and this rod was heated and drawn out into a thick thread. A number of these threads were bound together round a thick platinum wire and the individual rods fused together so as to form a tube. This tube was then drawn out, closed at one end, and shaped by blowing as is done in working glass, except that the quartz has practically to be worked in the blowpipe flame itself. Shenstone exhibited many articles which showed great manipulative skill in their manufacture.

At the fifth International Congress of Applied Chemistry in 1903, Dr. Heraeus read a paper on fused quartz, giving the results of his experiments

in fusing this material and producing articles of transparent silica. He also exhibited a very fine collection of apparatus manufactured in the workshop of Siebert & Kuhn, Cassel. The method employed by Heraeus was also chiefly a blowpipe one, though he made use of an iridium tube which I believe was heated electrically for the preliminary preparation of his raw material.

The methods of both Shenstone and Heraeus were developed commercially, the former by the Silica Syndicate of London and the latter by his own firm, W. C. Heraeus, of Hanau, though the methods now employed by these firms probably differ altogether from the somewhat crude methods which had to be adopted to begin with.

The methods which I have described so far are so expensive that large scale working was out of the question on account of the high price of pure rock crystal and the cost of using the oxy-hydrogen blowpipe. The attention of workers was therefore turned to the possibility of fusing silver sand, which contains over 99% silica, and to the adoption of electrical methods for fusing the material.

In 1902 Dr. Hutton read a paper before the American Electro-Chemical Society, in which he described some experiments in making tubes by fusing sand or particles of rock crystal. The material was piled round a central core and fused either by passing a current through the core or by playing an arc flame over the surface of the granulated material. The core was removed after the mass had cooled and a rough tube obtained.

In the same year Elihu Thomson in the United States took out a patent for making articles of fused quartz. By his process a core of the shape of the article required was embedded in sand and current passed through it till the sand had fused so as to take the shape of the core. The core was removed when the fused quartz was cold. Sometimes it had to be bored or burnt out.

About the same time Ruhstrat in Germany took out a patent for a very similar method of working. These methods, however, were of very limited application and did not lead to any practical result.

The chief difficulties in fusing quartz are due, firstly to its very high melting point, secondly, to the fact that the melting point and vaporising temperatures lie very close together, and thirdly, because there is no material sufficiently refractory to act as the containing vessel in which it can be fused, nearly all materials reacting with silica at the fusion temperature.

Heraeus in Germany has taken out a patent for the use of zirconia vessels for fusing quartz, but such vessels are not to be had at the present time in sizes which would be useful for practical working.

Before leaving the history of development of the manufacture of quartz, for the sake of historical accuracy I would like to refer to a statement which has been made in the German and Continental Press. The founder of the Deutsche Quarz Gesellschaft, Dr. Voelker, read a paper before the Dutch Chemical Society, at Nymegen in 1910, in which he claimed that a German firm, Ludwig Bolle und Co., which consisted of himself and Ludwig Bolle, had succeeded independently in 1904 in fusing sand. The facts of the case are the following: Ludwig Bolle und Co. was a firm engaged in exploiting certain electrical heating apparatus and furnaces but not in the manufacture of quartz, but for a short time they took up the sale of articles of fused silica manufactured at Wallsend. This arrangement lasted only a short time owing to financial difficulties and their firm went into liquidation. Dr. Voelker then became very much interested in quartz and spent several years in experimental work. His earliest patents were taken out in 1907 but were not of practical value; it was only in 1910 that the Deutsche

Quarz Ges. commenced to manufacture quartz by a process which led to patent litigation that ended disastrously for the German firm. I should not have referred to this matter but for the fact that it has been common practice for the Germans to claim priority for many new developments to which they are not entitled.

In the first experiments which we carried out at Wallsend in 1903, attempts were made to obtain a mass of molten quartz or sand in a liquid state and to work it much in the same way as glass is worked, but we very soon discovered that this was out of the question.

Although it is very difficult to get silica really fluid, it can be got into a plastic condition much more readily, and after a large amount of experimental work had been done, methods were evolved for working it in this condition.

The type of furnace employed is an electrical resistance one, the heating core or resistance consisting of plates, tubes, or rods of carbon or graphite. The limits within which such furnaces can be worked are exceedingly narrow because the temperature at which silica reacts with carbon to form carborundum is very close to the temperature required for working silica. The electric furnace, however, renders it possible to control the temperature of fusion, as accurate measurements are relatively easy.

In the manufacture of tubes or pipes the starting point is a hollow cylinder of plastic silica; this is formed by fusing a mass of sand round a central core through which the current is passed. The size of the cylinder is of course decided by the amount of electrical energy passed through the core and the length of time the heating is continued. As soon as the hollow cylinder has been formed the heating core is withdrawn from the centre of the mass, which can then be removed from the furnace and drawn into tubing. If a moulded article such as a pipe is required, the hollow plastic cylinder is closed at one end by mechanical pressure and a refractory nozzle, to which a source of compressed air is attached, pressed into the other end; the fused mass is then placed in the mould and expanded with compressed air till it assumes the required shape. The weight of fused material which can be worked at the present time exceeds 200 lb., and it is interesting to compare this with the small blowpipe pieces which were made by Shenstone and Heraeus in 1902. The temperature required for fusing silica is between 1800° and 2000° C. In the plastic condition it is extremely ductile and can be drawn out like glass in lengths of 90 to 100 feet.

The material made by the process I have described is rough on the outside, but small laboratory ware is subjected to a further process of grinding and finally glazing by melting the surface. This may be done electrically or by an oxy-hydrogen blowpipe.

Unfortunately owing to the extreme viscosity of plastic silica it is very difficult to remove the fine air bubbles which are found mixed with and contained in sand, and this has so far prevented the material made from sand from being entirely transparent, though very great improvements have been, and are still being, made in this direction. The lustrous appearance of some of the material is due to reflection from the included air.

The specific gravity of fused silica made from sand is 2.07 as compared with 2.2 for the material made from rock crystal. The coefficient of expansion of the two materials is practically the same, viz., 52×10^{-6} . A rod 1 metre long heated from 0° to 1000° C. expands 0.5 mm.

The properties of fused silica are now generally well known. Fused silica is unattacked by practically all acids except hydrofluoric acid and phosphoric acid above 400° C., and at the same time on account of the very small coefficient of expansion it is able to resist extreme changes of

temperature without cracking. These properties make it of great value for the manufacture of chemical plant.

At the outbreak of war there was a serious shortage of refractory and acid-proof material, which was very largely stoneware imported from Germany. Fused silica was to some extent able to make good the deficiency, and I am glad to say that in this respect it has played a considerable part in equipping the numerous factories which have been erected for ourselves and our Allies for the manufacture of explosives, especially in connection with the concentration of sulphuric acid and the condensation of nitric acid. For example, a large proportion of the nitric acid plants in this country have been fitted with Vitreosil condensers and conduit pipes, and we have also been able to supply our Allies with such plants.

Nitric acid plant.

A typical arrangement of the nitric acid plant is shown in Fig. 1. The cast-iron retort is connected by a silica socket pipe, A, with the range of silica conduit pipes, B, C, D, to the collecting piece, E; the branch pipes, F, lead the gases from E to the coils, G (only one shown), cooled by a water spray, where the main part of the condensation takes place. The residual nitrous gases pass out through H into the usual absorber, while the condensed nitric acid flows down the vertical pipe into a U tube, K, immersed in a small tank where cold water is circulated; thus the whole of the acid comes off at a low, uniform temperature. The cooled nitric acid flows off through the swan-neck pipe. A hydrometer floats in the exit side of the U tube, K. A very important feature in the design of the above plant is that all the joints have the socket below and vertical to protect the jointing cement, and prevent leakage of liquid or gas. A sightpiece in the small exit pipe allows the attendant to note the quantity and colour of the run of nitric acid.

FIG. 1.

With a retort of dimensions about 10 ft. deep and 7 ft. diameter this plant is capable of working off a charge of 2 tons of nitrate of soda, with its equivalent of sulphuric acid, in 8–10 hours. In this particular case the conduit pipes, A to E, are 8 in. internal diameter, and lead into four coils each 2½ in. diameter and 60 ft. long.

An alternative arrangement to the coils G (fig. 2) is a system of S pipes, four tiers of 4 in. diameter pipes having the same condensing surface as the above-described system of coils. These pipes are cooled by a spray of cold water, the same means being used for cooling the condensed acid.

Both these forms are extensively used, and give excellent results. The silica pipes and connections are comparatively light, simplifying the structural supports (not shown in the diagram). The whole of the pipes from C may be water-cooled without fear of breaking.

FIG. 2.

The condensing arrangements described above, being on the reflux principle, have the advantage of converting the greater part of the nitrous acid into nitric acid, and so increasing the yield of nitric acid, which thus contains the minimum amount of nitrous acid. This feature is absent from most other systems.

Concentration of sulphuric acid.

For the concentration of sulphuric acid the cascade system has been adopted in many of the largest factories, as on account of its simplicity of construction, ease in repairs, and continuity of working it presents great advantages. Fig. 3 (p. 580) shows one of the latest forms of cascade concentrating plants which has been adopted.

The sulphuric acid to be dealt with may be (a) pure, (b) de-arsenicated vitriol, or (c) waste acid from nitrating processes. These different qualities and strengths involve some changes in treatment, but in general the weak acid runs through a series of beakers, where the preliminary heating and some concentration take place; very little fume is given off in this portion. From the beakers the acid flows through pipes into a series of basins, where the concentration is completed; a good deal of fume is given off here, consequently this portion is covered, and the fume led into suitable condensing scrubbers, a slight vacuum preventing the escape of fumes into the air. The concentrated acid flows through a series of coolers. All the parts in contact with the acid are of silica.

A unit plant consisting of four rows, each row having 15 beakers and 25 basins, will yield 10 tons of concentrated sulphuric acid per 24 hours, with a fuel consumption of 20 per cent. on the acid produced. The silica-beaker arrangement of preheater has been found to be much more efficient than any form of open-tray system hitherto in use, having particularly the advantage over a lead preheater in that there is no danger of overheating and consequent failure of the lead.

The above figures of output relate to ordinary chamber or de-arsenicated acid of 100° or 110° Tw.—say 60% or 65% H_2SO_4 —concentrated to acid of 94.5 to 95.5%.

On the above plan the resulting acid is not contaminated by fire gases or from contact with any metal. The course of the fire gases is contraindicated to that of the acid. Fans are not necessary if a good chimney draught is available.

FIG. 3.

Denitration of mixed acid.

One other use in explosives factories which may be mentioned is the denitration of mixed acid from the manufacture of trinitrotoluol. This waste acid contains about 4 to 5% HNO_2 and HNO_3 , and it is advisable to separate these acids before concentrating the sulphuric acid. The operation is performed by running the waste acid down a tower, B (Fig. 4), packed with suitable material. A steam jet, S, is led into the base of this tower, carrying steam at about 50 or 60 lb. pressure, preferably slightly superheated, so as not to weaken unnecessarily the resulting sulphuric acid. The action of the steam is to separate the nitric and nitrous acids from the sulphuric acid, whence they are led from the top of the tower, D, through the pipe, E, into the receiver, F, thence through H into the coil, K, the outlet being led into the usual absorber. The condensed nitric acid flows through the outlet pipe, G. The denitrated sulphuric acid flows from the lead dish, A, to be pumped up to the concentrators. The plant as described, with a tower consisting of four pipes each 2 ft. 6 in. long by 2 in. diameter, is capable of dealing with about 10 tons of waste acid from T.N.T. manufacture per 24 hours.

In addition to the uses described above, there are many others for the material in the chemical and other industries, such as condenser pipes in the manufacture of hydrochloric acid and as basins, etc., for concentrating phosphoric acid, but to put it generally, fused silica is of value in all cases in which heat-resisting and acid-proof qualities are of importance.

FIG. 4.

Fused silica is already being

largely used for electric heating apparatus, and on account of its valuable insulating properties which are retained at relatively high temperatures, and to the fact that it is not hygroscopic in the same way as glass and china, it makes a very efficient insulator.

In conclusion I may say that as this is an entirely new process which is still in the stage of development, there is no doubt that the manufacture will continue to expand as regards size and variety of product and also as regards the sphere of useful application.

DISCUSSION.

The CHAIRMAN asked whether the joints in silica apparatus could be, or were, ground, and whether any difficulty was found in making joints.

Prof. H. LOUIS asked what was the silica content of the sand used, and said that sand containing 98.8% of silica could be obtained in the Midlands.

Mr. A. TROBRIDGE congratulated the Thermal Syndicate on the quality of their ware, and said he had yet to find a breakage in the silica parts of his nitric acid plant.

Dr. F. BOTTOMLEY, in reply, stated that grinding joints was not necessary, as a proper cement would keep them quite tight. The sand used contained about 99.7% silica. A suitable putty for joints consisted of 40 pts. of asbestos small, 8 pts. asbestos fibre, 10 pts. by weight of whiting, a little tallow, and the balance boiled linseed oil.

Industrial Notes.

JOINT COMMITTEE OF TECHNICAL ORGANISATIONS (ONTARIO BRANCH).

In the Annual Report for 1916-17 of the Joint Committee of Technical Organisations (Ontario Branch), of which Mr. Alfred Burton, of Toronto, is Chairman, it is stated that at a meeting of the executive officers of the various technical and scientific societies, instructions and associations of Ontario, held on the 28th December, 1916, in the rooms of the Engineers' Club, Toronto, a scheme was formulated for the creation of a Joint Committee of Technical Organisations, to consist of one representative from each society, institution, or organisation. These representatives were duly elected, and constitute the first Joint Committee. To facilitate prompt action an Executive Committee of five was named by the Joint Committee.

According to the by-laws, the aims and objects of the committee are "to devise ways and means by which engineers and other technical men may, as a result of their special training and experience, render assistance in the development and government of our Dominions. The immediate aim shall be to evolve a plan whereby such of these men as are unable to go to the front, may be used for war purposes at home in such a manner as their special technical training may make them most valuable." One of the by-laws also gave

power to the Joint Committee to elect "such other technical men, not exceeding five in number, as in their judgment could assist in carrying forward the work of the committee."

The question of organising similar committees in other provinces of the Dominion was immediately taken up with the various technical bodies in those provinces, and the idea has received hearty and, for the most part, enthusiastic support, so much so that joint committees have already been formed or are in process of formation in almost all of the provinces. The logical sequence, it is believed, will be the formation of a Dominion-wide Committee to give united expression to the aims and objects of the various joint committees.

One of the first activities of the Joint Committee, designed to form a basis of future operations, was to take a man-power census of all the members included under the plan of organisation. This necessitated, first of all, the compilation of a list including all the members of the various bodies—some 2500 in all. Cards were prepared and mailed to the last known address of every engineer and technical man in Ontario, and most of these have been returned. The information obtained by this means has been carefully filed, so that there is now available a systematic classification of the technical men of the province, together with their qualifications and special training and experience.

The attention of Government boards and commissions, engaged in carrying on the various phases of the war, has been drawn to the formation of the Joint Committee, as it was felt that it could be of assistance to them in many ways. Without exception, these bodies have expressed themselves as deeply appreciative of the value of such an organisation of technical men, and the committee is in close touch with the Imperial Munitions Board, the Honorary Advisory Council for Scientific and Industrial Research, the Department of Militia and Defence, and the Soldiers' Aid Commission. Other departments of the Government will be approached as time and opportunity offer.

The members of the committee have also interested themselves as a body in the question of the establishment of industrial research bureaux or laboratories at various points in Canada, for the purpose of co-relating more intimately the world of pure science with the world of commerce. The best method of procedure to further their aims is at present under consideration.

The committee has consented to act in conjunction with the Canadian Manufacturers' Association in obtaining information for the Advisory Council as to the present extent of, and resources for, research work at various points in the province. A questionnaire to fulfill this purpose has been prepared and is being sent to all manufacturers. A special sub-committee has been appointed to look after this part of the Joint Committee's activities.

Sub-committees have also been appointed to keep in touch with other activities undertaken, as follows:—*Imperial Munitions.* The sub-committee having this in charge is keeping in close touch with the Imperial Munitions Board, supplying technical men required by the board in munitions work, obtaining information as to materials required for war purposes, and giving other useful and special information. *Inventions.* This sub-committee has already passed upon a number of inventions submitted to us by the Imperial Munitions Board. *Recruiting.* The endeavours of the recruiting sub-committee have been chiefly along the line of improving the status of the ordinary sapper, whose work corresponds at least in importance to that of lieutenant in the infantry, though his status is merely that of a private. It

is also felt that something should be done to discourage or prevent technical men from enlisting in regular infantry battalions, where their special technical training is liable to be entirely lost to the Empire. *Returned soldiers.* This sub-committee has undertaken to follow up certain suggestions whereby plans might be put into effect for providing vocational training to returned soldiers, to assist them in adapting themselves, as their abilities may permit, to occupy better positions in life. Other plans are also being considered along similar practical lines. *Finance.* The finance sub-committee has gathered in sufficient voluntary subscriptions to enable the necessary expenses to be met to date and also to provide for the fitting out of an office. *Lists.* The lists sub-committee has been appointed to keep the lists up to date. *Classification.* The classification sub-committee has worked out and put into effect a very thorough and comprehensive card index system, which enables the secretary to place his finger immediately on any information required. *Suggestions.* Finally, a sub-committee has been named to initiate of itself, or receive from others, and report upon, suggestions of any nature pertaining to the activities, present or future, of the committee.

SOCIETY OF GLASS TECHNOLOGY.

At a meeting of the above Society held in the rooms of the Institute of Chemistry, Russell Square, London, on May 16th, Professor Herbert Jackson, F.R.S., gave a succinct account of the excellent work accomplished in glass research since 1911 at the instigation of the Institute and the Ministry of Munitions. One outcome of that work had been the placing of at least fifty new batch formulæ at the disposal of glass manufacturers, to experiment with, to adopt, and to improve. Amongst the most important formulæ available might be mentioned batches for (1) resistant and ordinary chemical ware; (2) soft glass for lamp work; (3) combustion tubing; (4) various types of glasses for X-ray work; (5) opal glasses; (6) thermometer glasses; (7) optical glasses. To show the widespread nature of the researches already carried out upon glass he mentioned that the effect of almost every known element had been tried and that many glasses with interesting properties were now available both for present and post-war use.

By fostering research in many directions and by the admission of science in its most advanced form into their industry, glass manufacturers had ensured its progress in the future. The outlook for the future was most encouraging and promising, for numerous interesting problems were needing attention whilst new ideas and new methods all required testing. The glass industry was a striking example of the co-ordination of the manufacturer and scientist at its best.

The lecturer then passed on to the properties of glass, dealing first of all with the relation between hardness and temperature of casting, and leading up to brittleness and the amorphous nature of glass. The causes of crystallisation were pointed out and the analogy between well-known crystallisation phenomena in pure chemistry and in actual glass manufacture was emphasised. In particular the necessity for homogeneity was commented upon. Given good homogeneity many of the problems of annealing, and faulty metal, would automatically disappear. The lecture concluded by the recounting of many new facts dealing with opal glasses and colour in glass, whilst lines on which research could be carried out were indicated.

BENZENE AND TOLUENE FROM PETROLEUM.

In view of the statements and claims that have been made in connection with the Rittman or "vapour-phase" process of producing benzene and toluene from petroleum oils, it is instructive to read an account of actual results on a commercial scale, by a chemist who has been in a position to judge the merits of the process. In the issue of the *Oil, Paint and Drug Reporter* for May 7th, Andrew Bender, chief chemist of the Carnegie Plant, Aetna Chemical Co., gives a short history of the working of this process by the Aetna Explosives Co. (which invested over £100,000 in the process), from the beginning until the plant was shut down last year. During this time many variations in size and kind of furnace tubes, pressure, temperature, method of heating, kind of oil used, and rate of oil feed were tried. During the last six months of operation, an average of 8500 gallons of oil per day was passed through the furnaces. The cracked oil contained an average of only 3% of benzene and 2½% of toluene on the oil used, and only about half of these quantities could be separated in a state of sufficient purity for profitable use.

The heavy oil obtained from the furnaces, containing considerable amounts of carbon, was allowed to settle and then distilled up to 175°C. The distillate was first freed from the relatively large amounts of sulphur dioxide and then separated into fractions corresponding to "heads," "crude benzol," "intermediates," "crude toluol," and "residue." The crude benzol and crude toluol fractions contained unusually large amounts of unsaturated hydrocarbons, which were removed by washing with sulphuric acid, after which the oils were washed with caustic soda and further rectified in stills of the Badger type. The presence of paraffin hydrocarbons having boiling points very near to those of benzene and toluene, respectively, rendered it impossible to produce high grade benzol or toluol, the best obtained being from 89 to 93% after repeated distillations. Some of the benzol was used for denaturing alcohol and some for conversion into phenol, whilst further quantities were blended with high-grade benzols. The toluene also was so contaminated with paraffins that it was useless for the manufacture of trinitrotoluene.

The cost of producing benzene and toluene by this process was far in excess of the high prices reached during 1915, and the author concludes from his experience that no possible cracking process could produce benzene or toluene at prices to compete with those at which these hydrocarbons were sold by Germany before the war.

INDIAN CHEMICAL TRADE IN 1915-16.

The annual "Review of the Trade of India," covering the twelve months ending March 31st, 1916, has just been issued as a blue-book [Cd. 8561].

From this report it appears that "chemicals, drugs, and medicines" is one of the few headings under which the imports show an appreciable improvement, the total value having increased from £1,368,000 in 1914-15 to £1,792,000; increases are noted in all the chemicals specified excepting caustic soda, potassium cyanide, and sulphuric acid. Imports of sulphuric acid only

amounted to 257 tons, against 1231 tons in the previous year and 3197 tons in 1913-14. Imports of coal, coke, and patent fuel fell to less than one-third of the imports in 1914-15. Coal-tar dyes also showed heavy decreases (91% in weight and 63% in value). Decreases are also noted in imports of metals and oils (mineral and vegetable), and increases in salt and sugar.

Sugar imports reached 515,000 tons, against 128,096 tons in 1914-15. The production of raw sugar is estimated to have been 2,636,000 tons in 1915-16, on an area of 2,375,000 acres, an increase of 7% in yield compared with the preceding year.

The amount of saltpetre produced in India increased from 15,500 tons in 1914 to 18,098 tons in 1915. Exports, of which about 80% went to the United Kingdom, amounted to 20,702 tons in 1915-16, an increase of 4303 tons over 1914-15. Increases are recorded both in the production and exports of coal, the figures for the year being 17,103,932 tons and 805,290 tons respectively.

Exports of indigo increased by 24,800 cwt. to 41,912 cwt., valued at £1,386,000; the quantity exported has not been exceeded since 1901. About three-fourths was sent to the United Kingdom, whilst the bulk of the remainder went to the United States and Egypt. The total area under indigo in 1915-16 was 311,300 acres—more than double that in the preceding year—and the yield of dye was estimated at 39,900 cwt. against 25,200 cwt. The first forecast for 1916-17 estimates a production of 75,200 cwt. on an area of 625,900 acres.

India is the principal source of supply of lac, and exports in the year under review amounted to 417,000 cwt., valued at £1,145,000. The quantity exported is the highest recorded for five years, but the prices continue to fall, the average having been £2 11s. 10d. per cwt., against £2 18s. 5d. in 1911-15. About 65% of the exports were to the United States and nearly 25% to the United Kingdom.

Exports of oil cake (all kinds) amounted to 150,282 tons, value £757,000; animal bones, fish manures and guano, and other manures totalled 60,178 tons, valued at £296,000.

The total exports of metals and ores were valued at £1,457,000. Exports of manganese ore amounted to 472,563 tons, value £554,000, and of tungsten ore 2787 tons, value £357,000; 80% of the manganese ore and over 90% of the tungsten ore was sent to the United Kingdom. It is estimated that the output of tungsten ore from Burma will reach 4000 to 5000 tons per annum. Exports of lead increased from 6518 tons in 1914-15 to 10,818 tons.

Oil-seeds generally experienced a considerable decrease in exports, the total value falling from £9,670,000 in 1914-15 to £6,582,000; increases were recorded, however, in ground nuts, mustard seed, and castor seed. Exports of vegetable oils and oil cakes increased in most instances, though decreases are reported in sesame oil, and in linseed and rape seed cakes (grouped together). Abnormally large exports of castor oil to the United Kingdom and of coconut oil to the United States are shown. The production of mineral oils, mostly in Burma, increased from 259 million to 287 million gallons, and exports from 26 to 28 millions; over 25,000,000 gallons of the exports consisted of benzine, petrol, and other motor spirit.

Exports of opium declined from 10,856 chests, value £1,176,000, to 8786 chests, value £980,000 (chest = 140 lb.). Of other exports, the following may be noted:—Raw rubber, £814,000; paraffin wax, £542,000; coal, £192,000.

Obituary.

PETER MACEWAN.

Peter MacEwan, Editor of the *Chemist and Druggist*, died suddenly at Highgate on May 16th, aged sixty.

Born at Lochee, Forfarshire, in 1856, he was trained as a pharmacist and followed that profession until 1885, when he joined the

editorial staff of the *Chemist and Druggist*, becoming Editor in 1899, a position he has filled with conspicuous success. He contributed a large number of papers on pharmaceutical subjects to various Associations and Journals, and was the author of several books, including the well-known works, "The Art of Dispensing" and "Pharmaceutical Formulas"; the latter was first produced in 1898 and has passed through nine editions.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56 Rue Ferou 8 Paris (3e.) Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Geysers, hot springs, etc.; Commercial utilisation of.—R. M. Gabrié. *Comptes rend.*, 1917, 164, 729—731.

ATTENTION is directed to the large amounts of energy which might be obtained from the natural steam jets and hot springs found in many countries. Since the temperature increases rapidly with depth, borings in the neighbourhood of hot springs would probably yield unlimited quantities of steam.—W. P. S.

Experiments with paper tubes. Rudeloff. *See V.*

PATENTS.

Drying apparatus. A. Sommermeyer, Berlin. Eng. Pat. 105,190, Aug. 26, 1916. (Appl. No. 12,098 of 1916.)

THE material is placed in a drum and is subjected to the disintegrating action of a rotary system of internally heated ribbed tubes.—W. H. C.

Dehydrating or drying apparatus. G. F. Humphrey, and Alliance Vegetable Co., Ltd., London. Eng. Pat. 105,626, Apr. 20, 1916. (Appl. No. 5825 of 1916.)

A PAIR of drying chambers are built back to back with air heating chambers above and below, so arranged that the air can be passed through both heating chambers and drying chambers in series or through either or both heating chambers and one drying chamber. The drying chambers are provided with superposed shelves on which the material to be dried is placed. The shelves are either arranged so as to leave a tapering air space at each end from which the air passes between the shelves in parallel; or they are perforated and the air is passed through all the shelves in series.—W. H. C.

Drying materials in vacuo; Means applicable for use in.—M. W. Blyth and T. V. Miles, Sheffield. Eng. Pat. 105,647, May 11, 1916. (Appl. No. 6770 of 1916.)

MATERIAL to be dried *in vacuo* is placed on shelves in a vessel provided with a cover which fits into an annular channel round the edge of the vessel. The channel contains paraffin wax, and a pipe is embedded in it so that the wax may be melted by passing steam through the pipe. The cover is placed in position and cold water passed through the pipe to solidify the wax and seal the cover. A number of such vessels are placed in a tank containing water heated by steam coils, and the

vessels are connected to a common pipe which is connected to an exhaust pump. The apparatus is specially applicable to the drying of guncotton.

—W. F. F.

Drying materials; Method of and apparatus for.—G. B. Damon, Belvidere, N.J., Assignor to Allis-Chalmers Manufacturing Co., Milwaukee, Wis. U.S. Pat. 1,222,079, Apr. 10, 1917. Date of appl., Aug. 2, 1915.

HOT gas from a producer, together with the material to be treated, is passed along the inner tube of a concentric rotary drying cylinder; the gas is then burned and the products of combustion used to complete the drying.—W. H. C.

Dryer; Mechanical rotary.—W. E. Prindle, Assignor to Buckeye Drier Co., London, Ohio. U.S. Pat. 1,222,211, Apr. 10, 1917. Date of appl., Aug. 5, 1915.

THE dryer consists of an inclined rotating cylinder through which the material is passed in the opposite direction to the heated products of combustion from a furnace. The latter enter the lower or discharge end of the cylinder through a fixed concentric pipe which extends some distance into the cylinder and serves to prevent direct contact between the material and the hot gases after the former has become nearly dry. A short screw conveyor is arranged on the inside of the rotating cylinder just before the open end of the inner pipe, to prevent the material from being thrown into the latter. The heated gases are withdrawn from the feed end of the cylinder by a fan.—W. H. C.

Agitator for dryers. J. Sorensen, Brooklyn, N.Y. U.S. Pat. 1,222,691, Apr. 17, 1917. Date of appl., Aug. 28, 1916.

SETS of relatively short scraping blades are mounted on a shaft within a drum, one set of blades being oppositely faced with respect to the other set. The blades can be simultaneously reciprocated longitudinally, and alternate blades rotated in opposite directions.—W. H. C.

Drying apparatus for asbestos or other material. J. N. Bourque, Thetford Mines, Quebec, U.S. Pat. 1,222,811, Apr. 17, 1917. Date of appl., Feb. 5, 1916.

THE material enters the top of a tower provided with inclined baffles on opposite sides alternately so as to retard the passage of the material. The lower part of the tower is connected with the inlet of a drying kiln, which comprises a rotating shell slightly inclined to the horizontal, and having

on its inner surface projecting longitudinal ribs carrying curved plates, forming a conveying worm which distributes the material in the kiln and conveys it slowly from the upper to the lower end. The lower end of the kiln is connected to the outlet of a furnace, and the hot gases pass over the material in the kiln and tower in the opposite direction, so that the material in traversing the tower is partly dried and preheated. The gases escape at the top of the tower through an outlet other than the inlet for the material.—W. F. F.

Dehydrator. C. Biesel, El Paso, Tex. U.S. Pat. 1,223,245, Apr. 17, 1917. Date of appl., Jan. 17, 1916.

A rotary drum has an annular peripheral space divided by partitions into separate chambers. The outer surface of the drum is covered with suitable screening material, and the chambers are separately connected to a valve on the shaft at one end of the drum. The valve consists of a rotary part which rotates with the shaft, and a fixed part which slides on the shaft and is pressed against the rotary part by a spring. As the drum rotates the valve puts the chambers successively into communication with means for producing suction or pressure.—W. H. C.

Drying chamber for liquid, fluid, and moist materials. W. Loebel, Leipzig. Ger. Pat. 295,799, Oct. 23, 1914.

The material is sprayed into a wide chamber on both sides of which, along the entire length, are air-suction chambers provided with filters, communicating with the lower part of the spraying chamber. Along the bottom of the chamber travelling bands are arranged on both sides and a roof-shaped ridge along the middle, so that the precipitated dry material is delivered from the filters and the ridge on to the travelling bands, which carry it outside before it has time to re-absorb moisture.—J. F. B.

Drying apparatus with moving wire band. A. Schultze, Dresden. Ger. Pat. 296,054, July 30, 1915.

The air jets in a drying apparatus through which the material is carried by a wire band, are so situated that they form a sharp angle in a direction opposed to that in which the material is travelling and overlap each other in the middle. The arrangement of the air jets has the effect of driving the lighter material towards the middle of the wire band but not of blowing it off on the other side. The accumulation of the material towards the middle of the band might impede the drying of that part, but the overlapping of the jets provides for a double supply of air at the middle.—J. F. B.

Drying drum. E. Peters, Charlottenburg. Ger. Pat. 296,834, Aug. 10, 1913.

The interior of the drum is divided into numerous compartments, e.g., by means of radial and annular partitions and with radial guide-plates, the inclination of which to the radial partitions can be adjusted so as to control the distribution of the material within the drum.—C. A. M.

Transference of heat between liquids and vapours or gases; Devices for the —. R. Sawyer and A. C. Ilston, Worthing. Eng. Pat. 105,127, Apr. 8, 1916. (Appl. No. 5191 of 1916.)

A HEAT-EXCHANGING device is formed of three concentric tubes. For example, water flows in one direction through the inner annular space, and is heated by steam which flows in the opposite

direction through the outer annular space. A rod may be used in place of the innermost tube.

—W. H. C.

High vacuum; Method of and means for obtaining —. The British-Thomson-Houston Co., Ltd. London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 105,357, Mar. 10 1916. (Appl. No. 3603 of 1916.)

IN a device for obtaining high vacua in bulbs for incandescence electric lamps, mercury vapour rectifiers, X-ray tubes, and the like, the vessel to be evacuated is connected to the pipe, 4, and mercury is evaporated in the bulb, 3. A jet of mercury vapour issuing from the tube, 1, carries gas from the tube, 4, with it, and passes to the condensing chamber, 5. Condensed mercury collects in the chamber, 6, and returns to the bulb, 3, by the pipe, 7. Back flow of mercury vapour through the pipe, 4, is prevented by surrounding the enlargement, 9, with a condensing jacket, 10. The gas in the chamber, 5, is withdrawn by an exhaust pump attached to the pipe, 8. Aniline, chloroform, or water may be used in place of mercury.—W. F. F.

Ball-mills. W. Everitt and Co., Ltd., and W. Everitt, Southall, Middlesex. Eng. Pat. 105,614, Apr. 19, 1916. (Appl. No. 5742 of 1916.)

IN a ball-mill with cylindrical wall, the internal surface of the wall has longitudinal ribs formed integrally with the wall itself so as to increase the play of the balls.—W. H. C.

Pulveriser; Centrifugal —. H. Adams, Stamford, Conn. U.S. Pat. 1,221,952, Apr. 10, 1917. Date of appl., Apr. 6, 1914. Renewed Oct. 21, 1916.

Two horizontal, rotary discs are spaced apart, and have series of annular ribs of triangular cross-section mounted on their opposed faces. The material to be ground is fed through an opening in the upper disc on to the lower disc.—W. H. C.

Grinding-mill. D. Cole, Tucson, Ariz. U.S. Pat. 1,222,184, Apr. 10, 1917. Date of appl., Apr. 28, 1913.

THE material to be ground is fed through one of the hollow axial shafts of a rotary grinding chamber and, after being ground, flows along with the water to a sorting chamber, which forms an extension of, and rotates with, the grinding chamber. The finely ground material flows away with the water through the other hollow axial

shaft, and the larger pieces, which separate in the sorting chamber, are returned to the grinding chamber by a screw-conveyor fixed within the sorting chamber.—W. H. C.

Separator for grinding-mills. W. J. Price, Dixon, Ill. U.S. Pat. 1,223,612, Apr. 24, 1917. Date of appl., May 11, 1916.

THE material from the grinding-mill is delivered to the apex of a cone fixed within a vertical cylindrical casing having conical ends. A current of air is directed against the cone and carries the finer particles upwards to the fine material outlet at the apex of the upper conical end. This outlet is connected to a suitable means of creating suction and has an adjustable conical deflector, suspended below, which serves to collect any coarse particles carried upward by the air current, and to return them through an opening in the apex of the retarding cone below. The coarser particles gravitate to an outlet at the apex of the lower conical end of the casing.—W. H. C.

Straining liquids [e.g., oil fuel for internal combustion engines]; Apparatus for— Cammell Laird and Co., Ltd., Birkenhead, and G. J. Carter, Bromborough, Cheshire. Eng. Pat. 105,630, Apr. 25, 1916. (Appl. No. 5882 of 1916.)

THE apparatus is particularly suitable for straining oil for internal combustion (e.g., Diesel) engines and the like. A cylindrical plug, B, fitting in a casing, A, is provided with a series of fine transverse peripheral triangular grooves, G, about 60

to the inch. Passage-ways, *i*, are cut longitudinally in the periphery of the plug, extending from one end nearly to the other, and alternate passage-ways, *o*, are similarly cut from the opposite end of the plug. Oil entering at I, passes into the passages, *i*, through the grooves, G, to the passages, *o*, and thence to the outlet, O. Two or more strainers may be used in series or parallel, and when in series, the first may have coarser grooves. The grooves may alternatively be formed in a conical or plane surface. In a modification, the inlet and outlet passages, *i* and *o*, each extend halfway along the plug, and intermediate parallel recesses, *l*, closed at the ends, are provided between them, the effect being that of two plugs in series. In another modification, the plug is hollow with a diametral partition forming inlet and outlet chambers. Transverse circular grooves are cut eccentrically alternately on opposite sides of the partition, so as to cut through the wall on one side but not on the other side of the partition alternately. Fine spiral grooves, corresponding to G, are cut in the outside of the plug. The liquid passes from the circular transverse grooves communicating with the inlet chamber, through the fine spiral grooves, to the transverse grooves communicating with the outlet chamber.—W. F. F.

Liquid sprayers or atomisers. T. Andrew, Heaton Moor, Cheshire. Eng. Pat. 105,687, July 25, 1916. (Appl. No. 10,467 of 1916.)

IN atomising or spraying apparatus in which liquid and compressed air are used, a valve is provided for automatically cutting off the liquid supply when the air falls below a predetermined pressure. A piston or lift valve, closed by a spring or weight, is placed in the liquid-supply pipe, and carries a piston or diaphragm on its spindle, to which the compressed air is admitted by a branch pipe so as to lift the valve against

the action of the spring or weight at a predetermined pressure. Another valve of this type may be arranged to open when the air pressure falls below a predetermined amount and thus drain the liquid from the pipes.—W. F. F.

Cloth for filter-presses. H. H. Hanson, Boston, Mass., Assignor to Berlin Mills Co., Berlin, N.H. U.S. Pat. 1,222,100, Apr. 10, 1917. Date of appl., July 8, 1916.

THE cloth is woven from threads of suitable textile material which are impregnated with indiarubber to render the cloth resistant to the action of caustic alkalis.—W. H. C.

Filter; Renewable— Dr. North Kommandit-Ges., Hannover. Ger. Pat. 296,715, Mar. 23, 1915.

THE filtering medium consists of silicon carbide (carborundum), which has been made into a paste with water or other binding agent and ignited. It is then left as a porous mass, which is not attacked by acids and can be repeatedly purified by ignition. It is particularly suitable for the filtration of strong acids, and, in the heated condition, as a filter and vaporiser for volatile oils, etc. The impurities left in the filter can be removed by burning, or by washing with a suitable liquid.—C. A. M.

Regenerative furnaces. H. E. Smythe, Assignor to S. R. Smythe Co., Pittsburgh, Pa. U.S. Pat. 1,222,699, Apr. 17, 1917. Date of appl., May 15, 1915.

THE furnace is provided with regenerators below the sole and with a preliminary combustion chamber at the side of the regenerator chamber. Gas is supplied to the preliminary combustion chamber and burned by partly-regenerated air, and the resulting products of combustion are delivered to the furnace chamber proper, where they are intimately mixed with fully-regenerated air and the combustion is completed.—W. H. C.

Kiln. J. A. Reams, Assignor to W. J. Parrish, Richmond, Va. U.S. Pat. 1,223,732, Apr. 24, 1917. Date of appl., Sept. 20, 1916.

AN open-ended tunnel kiln is divided into a series of zones connected by flues. Air is passed laterally across the kiln in the zone at the exit end, thence back across the tunnel in the form of products of combustion, thence again across the tunnel in another zone, and finally across the tunnel in a zone at the inlet end.—A. B. S.

Gas and other fluids; Apparatus for separating vapour from— L. C. Frohrieß, Pittsburgh, Pa. U.S. Pat. 1,222,751, Apr. 17, 1917. Date of appl., July 19, 1916.

A VERTICAL cylindrical chamber is provided with an inlet and an outlet opposite one another about midway of its height. A vertical baffle-plate, with a series of inclined troughs on one side and perforations between the troughs, is placed opposite the inlet with the troughs facing the latter. A travelling belt of fibrous absorbent material moves vertically closely behind the baffle-plate, being carried by an endless chain which passes over two sprocket wheels. A non-perforated baffle-plate is placed behind the belt. The belt is longer than the chain and the slack portion passes between a pair of rollers to squeeze out the moisture.—W. F. F.

Gases [air]; Apparatus for purifying— A. Bart, Cottbus. Ger. Pat. 296,636, June 27, 1914.

THE air or gas is passed through two adjacent vertical purifying chambers, between which are channels which deflect the current from the upper

part of one chamber to the lower part of the other. The chambers may also contain transverse ledges inclined downwards and reaching nearly to the bottom, the object of which is to catch dust and promote uniform circulation of the air, etc.

—C. A. M.

Gases and vapours: Purification of—by the dry method. C. Grosse, Metz. Ger. Pat. 296,837, Sept. 2, 1913.

IN the purification of blast-furnace gas, producer gas, etc., by the dry method, a portion of the filtered gas, which in the course of purification has been cooled to a low temperature, is mixed with the hot crude gas, after being again brought to the same temperature as the latter. By this means the crude gas is dried, and clogging of the filter is prevented. For this purpose, also, a current of the purified gas may be passed through the filter in the reverse direction before being mixed with the crude gas.—C. A. M.

Deplegation: Apparatus for— R. R. Rosenbaum, Chicago, Ill. U.S. Pat. 1,222,801, Apr. 17, 1917. Date of appl. Aug. 22, 1916.

A VERTICAL cylindrical casing, having a vapour inlet at the bottom and outlet at the top, contains a series of deep pans, one above the other, each surrounded by an annular space. A horizontal partition is arranged above each pan, with a central reticulated opening having a wide tube depending into the pan below. Each tube is surrounded by a cooling coil, and pipes are provided for discharging condensed liquid from the pans, and for conveying condensed liquid from the upper pans to the partitions over the lower pans. The vapour passes upwards through the annular space, downwards over the cooling coil, and upwards through the central tube to the next compartment.—W. F. F.

Liquids: Method of treating [solidifying]— F. D. Crane, Montclair, N.J. U.S. Pat. 1,223,153, Apr. 17, 1917. Date of appl. Jan. 8, 1917.

A LIQUID is solidified by dissolving in it a suitable fatty acid, such as stearic acid, and adding an alcoholate, such as a solution of sodium ethoxide in an excess of ethyl alcohol.—W. F. F.

Deflocculating solid materials: Method of— E. G. Acheson, Assignor to Acheson Corporation, New York. U.S. Pat. 1,223,350, Apr. 21, 1917. Date of appl. Jan. 17, 1917.

SOLID material made into a paste with a deflocculating agent is submitted alternately to periods of attrition and relative rest until the desired result is attained.—W. H. C.

Centrifugal separators. T. E. Brown, New York. Eng. Pat. 100,317, Apr. 17, 1916. (Appl. No. 5620 of 1916.) Under Int. Conv., Apr. 16, 1915. SEE U.S. Pat. 1,159,711 of 1915; this J., 1916, 31.

Filter medium for cleaning furnace gases. F. E. Kling, Youngstown, Ohio, U.S.A. Eng. Pat. 105,884, Jan. 19, 1917. (Appl. No. 977 of 1917.)

SEE U.S. Pat. 1,215,385 of 1917; this J., 1917, 377.

Dehydrating or drying apparatus. G. F. Humphrey, Assignor to Alliance Vegetable Co., Ltd., London. U.S. Pat. 1,225,631, May 8, 1917. Date of appl. Sept. 29, 1916.

SEE Eng. Pat. 105,626 of 1916; preceding.

Method and apparatus for evacuating bulbs of electric incandescent lamps and other glass vessels. Eng. Pat. 101,621. See 11b.

Packing rings [from viscose]. Ger. Pat. 296,405. See V.

Oil-fired [melting] furnaces and the like. Eng. Pat. 105,431. See X.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Nitrogen in coal and coke: Chemical condition of— E. Terres, J. Gasbeleucht., 1916, 59, 519—521. Z. angew. Chem., 1917, 30, Ref., 46.

IN carbonisation 10—65% of the nitrogen of the coal remains in the coke, 10—14% is recoverable as ammonia, and the rest is lost as free nitrogen or cyanogen in the gas, a little, however, being found in the tar. By slow distillation it is possible to recover as much as 35% as ammonia, and it seems probable that the nitrogen is split off in the first place as ammonia. The author has attempted to discover what classes of compounds yield ammonia on distillation. Glycocoll, asparagine, egg albumin, animal glue, pyridine, azobenzene, hydrazobenzene, acetonitrile, phenyl isocyanate, and nitrobenzene were all subjected to dry distillation. Ammonia was liberated from the amino and substituted amino compounds only. The conclusion is drawn that the nitrogenous compounds of coal must have the character of proteins. In coke, the nitrogen is probably in the form of a nitride of carbon, as suggested by Rau and Christie. This is confirmed by the experiments of Sachs (this J., 1916, 346), who showed that on gasifying coke with air and steam, 89% of the nitrogen could be recovered as ammonia.—H. J. H.

Sulphur-content of coke: Influence of air and water on— J. R. Campbell, Gornosawodskoje. Djelo, 1916, 23, 13,667. Chem.-Zeit., 1917, 41, Rep., 42.

THE sulphur content of beehive oven coke is not lower than that of by-product oven coke, in spite of the greater access of air in the non-recovery ovens. This is due to the higher yields obtained in by-product ovens. Sulphur present as sulphates in the coal is not driven off at all in carbonisation, and hence it is not possible to produce coke of low sulphur content where the coal ash is basic. Quenching coke with water causes a smell of hydrogen sulphide, but only a small quantity of sulphur is removed thereby. Much more sulphur could be removed by quenching with hydrochloric acid solution.—H. J. H.

Benzol [from coal gas]: Recovery of—by a modified dehydrating plant. E. F. Keable, Eastern Counties Gas Managers' Assoc., May 3, 1917. Gas J., 1917, 138, 288—292.

THE author describes his adaptation of a "Hird" dehydrating plant for debenzolising wash oil. Seven tanks are used. One is sunk below ground to receive the tank-cart delivery of wash oil, which is thence pumped to a main storage tank afterwards passing by gravity to the feed tank of the washer. The latter is a Kirkham, Hulett, and Chandler centrifugal washer, ammonia being removed in the bottom three trays, the remainder being fed with creosote oil at the rate of 50 to 60 galls. per ton of coal. The oil is kept at a temperature above that of the gas and the benzolised oil passes by gravity to another tank, whence it is pumped to the main benzolised oil-storage tank. It then passes through a feed tank to the still; the debenzolised oil is cooled first by incoming benzolised oil, secondly by cold water. The cooled oil passes into the underground tank,

thus completing the circuit. A fractionating column has been fixed to the outlet of the original condenser, one end of the column being sealed in a pot with suitable overflow, the other end being connected to the water-cooled tubular benzol condenser; the waste gases pass through a small line purifier. A supply of live steam has been added to the still, one central supply being fixed in the crown. The steam is superheated by insertion of the feed pipe into the waste gas flue. Before entering the still the oil is raised to 70° C. in the preheater. The steam used in the still is equal to an evaporation of 10 lb. of water per gallon of spirit produced, and the plant has been found capable of dealing with 70 to 80 galls. per hour. With a still temperature of 129° C., steam pressure of 60 lb. per sq. in., and rate of oil flow 70 to 80 galls. per hr., an average of 2 galls. of spirit, testing 68% at 120° C., has been obtained per ton of coal. The oil is saturated to 5%, leaving only 0.2 to 0.8% at 180° C. in the debenzolised oil. Light cresote oil low in naphthalene and of sp. gr. 1.02 is used for absorption. The sulphur compounds in the gas have been reduced 27%, the illuminating power 23%, and the calorific value 5%.—J. E. C.

Benzol recovery plant: An experience in a—
Gas J., 1917, 138, 285.

BENZOLISED oil entering the plant passes through a preheater, absorbing heat from the benzol vapours from the still, and is then heated in a superheater by closed steam coils, the normal temperature reaching 130° C. On one occasion there was a gradual decrease in temperature of the oil leaving the superheater until, even with full steam, it was not possible to obtain a temperature higher than 105° C. Examination of the coil in the superheater showed it to be covered with a layer, about $\frac{1}{8}$ -inch thick, of a dark grey substance, found on analysis to consist almost entirely of sodium sulphate with a little free carbon. The source of this deposit was traced to the practice of putting back into circulation the "bottoms" from a washed solvent naphtha distillation. Evidently a little emulsion containing sodium sulphate found its way into the residue of the still, and on passing into circulation caused a deposit when in contact with the hot surface of the coil. Normal results were again obtained after cleaning the coil and avoiding any further re-circulation of "bottoms."—J. E. C.

Acetone and air: Propagation of flame in mixtures of—. R. V. Wheeler and A. Whitaker.
Chem. Soc. Trans., 1917, 111, 267—272.

THE authors have determined the limits of inflammability and the speed of propagation of flame for mixtures of acetone and air. The limits are tabulated as follows in percentages by volume of acetone:—

Diameter of tube, cm.	Lower limit.			Higher limit.		
	Downward.	Horizontal.	Upward.	Downward.	Horizontal.	Upward.
2.5	2.75	2.40	2.30	6.5	6.7	7.5
5.0	2.40	2.25	2.20	8.3	9.3	9.5
10.0	2.35	2.20	2.15	8.5	9.5	9.7

The speed of flame propagation in a tube 2.5 cm. in diameter was about 55 cm. per sec. with 2.7% acetone, rising to a maximum of about 96 cm. per sec. with 5.5% acetone, and falling to about 31 cm. per sec. with 8.2% acetone. With wider tubes these velocities will probably be greater (e.g. about three times as great for a 60 cm. tube).—W. H. P.

Petroleum spirit: Inflammability of— at low temperatures. J. H. Coste. Analyst, 1917, 42, 168—170.

SAMPLES of motor spirit were cooled by means of liquid air in a thin test-tube 100 mm. long and 25 mm. in diameter, and the tube then transferred to a Dewar tube in which it was supported by means of a card with a hole in the centre. The tube was covered with a card (which was removed at each trial) and the liquid was tested with a small flame at intervals of about 2° C. until it flashed. The temperatures were determined by means of a copper-eureka thermo-couple, with the "hot" junction in ice and water, and the "cold" junction immersed to about 18 mm. in the liquid. The thermo-couple was calibrated by means of the solidification points of monobromobenzene (−31.1° C.), mercury (−38.8° C.), chloroform (−70° C.), toluene (−97° C.), and by means of liquid air. A mirror galvanometer was used and the deflections observed at a distance of 1 m. were taken. The following results were obtained:—Pratt's motor-spirit solidified at −128° C. and flashed at −30° C. (−22° F.) (surface of liquid 18 mm. from the top of the tube). "Standard" spirit flashed at −11° C. (+12.2° F.) (surface of liquid 50 mm. from the top of the tube). "Shell" spirit flashed at −16° C. (+3.2° F.) (surface 50 mm. from the top of the tube). A sample of fairly pure acetone solidified at −96° C. (pure acetone = −95° C.) and flashed at −9.5° C. (+14.9° F.). These results show that ordinary motor spirit is dangerous to handle near a flame at any temperature likely to occur in this country, but that it is not likely to give trouble (as benzene might) in arctic temperatures.—C. A. M.

Benzine and motor oil: Production of— by heating lignite products under pressure. F. Fisher and W. Schneider. Braunkohle, 1916, 15, 291—293, 299—301, 307—310. Z. angew. Chem., 1917, 30, Ref. 66.

THE following yields of the lightest (up to 150° C.) and middle (150—300° C.) qualities of benzine have been obtained by repeatedly heating the products named under pressure:—

	Lightest quality.	Middle quality.
Montan wax	30	29
Paraffin	48	22
Lignite tar	25	29

The products had the following calorific powers:

	Light benzine.	Heavy benzine.	Middle oil.
Montan wax ...	10,268	11,171	10,915
Paraffin	10,780	10,850	10,820
Lignite tar	10,399	10,853	10,636

The flash point of the light and heavy benzine was under 30° C., that of the middle oil from montan wax was 38°, from paraffin 39°, and from lignite tar 41° C. It is possible that similar products may be obtained on a large scale without using high pressures.—A. B. S.

Tars and tar distillates as temporary substitutes for heavy petroleum oils. H. Moore. Petroleum World, 1917, 213.

THE spontaneous ignition test (this J., 1917, 109) may be utilised to ascertain if fuels for Diesel engines require pilot ignition. The high ignition points of coal tar distillates necessitate pilot ignition. Raw coal tars can be burned with pilot ignition, provided the free carbon content is not high.—F. W. A.

PATENTS.

Peat; Apparatus for treating [extracting water from]—. W. L. St. J. Prioleau, London. Eng. Pat. 105,396, Apr. 11 and May 2, 1916. (Appl. Nos. 5309 and 6295 of 1916.)

WET peat, preferably after treatment by freezing, is passed from a hopper through a pair of crushing rolls with surfaces corrugated longitudinally, and falls on to a heated band of absorbent material, such as felt, travelling horizontally, which passes round a steam-heated drum to evaporate the absorbed water. The peat is removed from the band by a scraper and passes through a pair of crushing rolls with coarse transverse corrugations, to another similar absorbent travelling band, from which it passes through a third pair of crushing rollers with smaller transverse corrugations. The absorbent band may be replaced by slightly inclined, perforated, vibrating trays. The peat passes from the third pair of crushing rolls into a briquetting press which removes any remaining moisture, and the briquettes are discharged on to a conveyor for subsequent heat treatment or the like.—W. F. F.

Gas producer plant. C. Whitfield, Kettering, Eng. Pat. 105,419, June 1, 1916. (Appl. No. 7759 of 1916.)

IN a producer-gas plant of the suction or pressure type, the gas leaving the producer at the top passes down through a vertical pipe having a central rod on which unglazed earthenware blocks are threaded so as to leave an annular space. The pipe has a spiral groove on the outside over which cooling water trickles and is evaporated, and the whole is surrounded by an outer pipe having an inlet at the top, and an outlet at the bottom leading to the ash-pit of the producer, so that the air supply to the producer is heated and moistened. After leaving the cooling pipe, the gas passes through a tar extractor of the type described in Eng. Pat. 1118 of 1913 (this J., 1914, 190) to a gas-holder. The inlet pipe of the gas-holder extends centrally nearly to the top and carries a horizontal disc close above it. A concentric sleeve slightly larger than the pipe is suspended from the gas-holder bell, so that when the gas-holder is full, the sleeve comes into contact with the disc and thus closes the inlet.—W. F. F.

Gases; Separation of tar and condensable products from—. E. Haunemann, Graz, Ger. Pat. 296,065, Mar. 9, 1915. Under Int. Conv., Mar. 10, 1914.

THE gas passes through holes in vertical plates and impinges upon baffle-plates behind, to which the tarry particles adhere and down which they drain. This tar separator is fitted with arrangements of screens to cover or uncover at will the openings in the plate, so as to vary the number and area of the holes available for the passage of the gas. A claim is also made for an apparatus in which the gas passes through slits, the width of which can be varied at will. The object to be attained is a variation as desired of the resistance to the passage of the gas and accordingly of the impact on the baffle-plate behind the holes.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Wood and other vegetable products; Distillation of—. Bull. Imp. Inst., 1916, 14, 566—577.

DESTRUCTIVE distillation trials have been conducted at the Imperial Institute, under conditions approximating to those which would be used in modern works, in connection with the possible initiation of wood distillation industries in Natal, where it is proposed to use wattle wood; in Uganda, where experiments have been made with *Podocarpus milanjianus* with a view to the preparation of a preservative against white ants; in Ceylon, where vera or virai wood (*Hemicycia sepiari*, W.A.) has been tried with a view to the production of acetic acid for coagulation of rubber; and in Egypt, where cotton stalks may be utilised. The results obtained with wattle, olive, pine, and oak are summarised in the table, together with factory results with oak wood.

	Average results of small scale trials at Imperial Institute.				Factory results with oak wood.
	Black wattle.	Olive wood.	Pine wood.	Oak wood.	
Acetic acid	4.7	3.0	2.2	4.4	3.8
Equivalent to acetate of lime	6.2	4.0	2.9	5.8	5.0
Methyl alcohol	1.2	1.6	0.6	1.1	1.1
Tar separated	6.0	7.4	12.9	6.4	4.5
Charcoal	27	29	29	25	26

From these results, taken in conjunction with the results of an examination of the charcoals, it appears that both wattle and olive wood should be at least as profitable to distil as oak. An examination was also made of coconut shell charcoal and vera wood charcoal from Ceylon, and the results are tabulated, in comparison with other fuels, below.

	Calorific value.	Moisture.	Volatile matter.	Carbon.	Ash.	Sulphur.
	Small calories.	%	%	%	%	%
Wattle wood charcoal	7615	20.87	—	77.78	1.35	0.28
Olive wood charcoal	7645	24.58	—	72.90	2.52	0.09
English black charcoal (compressed)	7607	6.80	9.52	82.57	1.11	0.10
English rough charcoal	7413	8.29	7.03	82.56	2.12	0.15
Rhodesian charcoal	7218	4.17	29.97	71.51	3.35	0.07
"Standard" coal (steam coal)	7400	—	—	—	—	—
Welsh coal briquettes	7800	1.0	15.0	80.0	4.0	—
S. Nigeria lignite briquettes	6522	7.14	53.80	53.35	5.71	0.67
German lignite briquettes	5575	15.67	48.28	28.28	7.46	3.29
Coconut shell charcoal	7529	4.7	18.2	76.1	1.0	0.05
Vera wood charcoal	6575	38.2	—	56.6	5.2	0.4

A sample of acetate of lime from Ceylon was a coarse grey powder giving a dark brown solution, and containing moisture, 3.5; calcium acetate, 83.6; sulphates (as CaSO_4), 0.60; carbonates (as CaCO_3), 0.08; ash, 32.2%. No free lime, calcium formate, or sulphites were present.

—E. W. L.

Charcoal [from sulphite-cellulose waste liqrs] : Process for the production of — A. Knöpfmacher, Vienna. Eng. Pat. 102,608, Oct. 13, 1916. (Appl. No. 14,594 of 1916.) Under Int. Conv., Dec. 4, 1915.

A MIXTURE OF sulphite-cellulose waste liquor 4000 kilos., potassium carbonate 400 kilos., calcium oxide 38 kilos., and ground unburnt lime 60 kilos., is evaporated to dryness, and heated to redness in an iron vessel with the exclusion of air, the evolved gases being drawn off. The resulting material is treated in a Shanks lixiviating apparatus, and the residue extracted in a centrifuge or filter press. The calcium compounds may be extracted by means of acids, e.g., hydrochloric acid, and the remaining charcoal dried and ground. The filtered potassium carbonate solution of about 25° B. (sp. gr. 1.21) is mixed with about 30 kilos. of potassium bicarbonate, evaporated to 50° B. (sp. gr. 1.33), drawn off from the slight residue of potassium sulphate, and added to a fresh quantity of waste liquor for treatment as above. About 100 kilos. of highly active decolorising charcoal is obtained. To obtain charcoal free from ash, a mixture of waste liquor 4000 kilos., calcium oxide 38 kilos., and unburnt lime 100 kilos. is evaporated to dryness and the residue lixiviated with 615 litres of potassium carbonate of density 45° B. (sp. gr. 1.45) derived from the preceding operation. The mixture is filtered, dried, and heated to redness, and then treated as in the first example, with the omission of the acid treatment.—W. F. F.

Incandescent lamps and other glass vessels ; Method of and apparatus for evacuating bulbs of electric — Deutsche Gasglühlicht A.-G. (Auergeres.), Berlin. Eng. Pat. 101,621, July 7, 1916. Under Int. Conv., Sept. 27, 1915. (Appl. No. 9608 of 1916.)

EACH of two removable receivers, one within the other, is provided with a base plate, the space between the two receivers and the space enclosed by the inner receiver having separate connections for exhausting them. The edge of the inner receiver is sealed by a metal of low melting point and low vapour tension, forming a liquid seal on the outer edge of the base plate of the inner receiver, and the latter is heated electrically. One or more plates are arranged within the inner receiver for supporting electrical heating plates, and the openings of the nipples of the bulbs are also supported by the plates during the exhausting and sealing operations; or the bulbs may be held away from the heating plates during exhaustion, and brought into contact with them for sealing off the lamps when the desired vacuum has been established. The free end of each

nipple may be sealed off by a piece of glass, of lower melting point than the glass of the bulb placed within the nipple. The bulbs are supported upon a frame provided with partitions, and may be heated before being placed in the receiver to substantially the same temperature as is obtained later in the receiver.—B. N.

Hydrocarbons and pure carbon ; Production of — from bituminous lignite. P. Schröder. Ger. Pat. 296,539, July 3, 1914.

ACCORDING to Ger. Pat. 295,296 (this J., 1917, 206), raw lignite is converted into a colloid on treating it in a grinding cylinder with hot water containing alkali salts. The colloidal solution is filtered and the filtrate acidulated so as to coagulate the colloids, whilst any inorganic matter remains in solution. It has since been found that if the coagulated product is distilled with superheated steam or other gases at 500° C. and a pressure of 50 atmos., a yield of 18–30% of solid, liquid, and gaseous hydrocarbons and an almost chemically pure carbon are obtained. The raw lignite does not produce so high a yield with superheated steam and no pure carbon is obtained.—A. B. S.

Flame-arc lamp and electrode therefor. G. Egly, Assignor to Gebr. Siemens und Co., Berlin-Treptow, Germany. U.S. Pat. 1,221,039, Apr. 3, 1917. Date of appl., Nov. 26, 1915.

THE negative electrode contains boric acid evenly distributed throughout to prevent the formation of slag, and the positive electrode contains luminous admixtures.—B. N.

Metallic filaments ; Preparation of — J. Pinfisch A.-G., Berlin. Ger. Pat. 296,191, Jan. 20, 1914. Addition to Ger. Pat. 291,994 (see Fr. Pat. 469,212; this J., 1915, 36).

WHEN the metallic wire consists of a single crystal over its whole cross-section (*loc. cit.*) and of

relatively great length, it can be easily drawn through a die, if the speed be not excessive. The internal structure of the wire is thereby left unchanged, the crystal being merely lengthened. It is possible by the process described, to correct for irregularities in metallic filaments by simple wire drawing.—H. J. H.

Destructive distillation of wood and the like. S. E. Seaman, Gauley Mills, W. Va., Assignor to Seaman Waste Wood Chemical Co., Inc., New York. Reissue No. 14,300, May 8, 1917, of U.S. Pat. 1,108,403, Aug. 25, 1914. Date of appl., July 28, 1916.

III.—TAR AND TAR PRODUCTS.

Toluene and benzene; Estimation of — in coal tar oils. G. Harker. J. Roy. Soc. N.S.W., 1916, 50, 99—105.

IN estimating toluene and benzene in coal tar oils, it is usual to subject the tar oil to a preliminary distillation to 150° or 170° C., followed by a washing of the distillate with sulphuric acid and caustic soda. The washed product is then distilled under conditions varying considerably. From the volume of the fraction collected between certain temperatures and by reference to tables, the composition may be deduced, but the range of such tables is limited and occasionally pure benzene, toluene, or xylene must be added before distillation (see Colman, this J., 1915, 168; James, this J., 1916, 236). The author has carried out a series of experiments with pure benzene, toluene, and xylene. A Young and Thomas still-head of five sections was used and the rate of distillation was kept at one drop per second. When mixtures of benzene and toluene in the proportion of 3:1 or 4:1 were distilled, the volume distilling over up to 90° C. represented the volume of benzene present. With mixtures of 50 c.c. of benzene and 50 c.c. of toluene, the first 50 c.c. came over slightly above 95° C. Additions of xylene necessitated a still higher temperature. The actual content of benzene and toluene in the samples was obtained by carrying out a blank test after each distillation of the sample. In this blank test, quantities of pure benzene, toluene, and xylene were added to the residue in accordance with the approximate estimation. The mixture was again distilled, whereby any error in the first estimate was corrected. After a preliminary distillation up to 170° C. the distillate was washed with sulphuric acid and caustic soda (cf. Davis, Lunge and Keane's Tech. Methods of Chem. Anal., vol. 2, part 2, p. 767). The washed oil was then distilled and a blank test carried out as described. Paraffins present were estimated by a sulfonation test with anhydrous sulphuric acid (cf. Lunge and Keane's Tech. Methods of Chem. Anal., vol. 2, p. 799; and Allen's Commercial Organic Analysis, 4th ed., vol. 3, p. 241). Details of tests on three samples of coal tar oil of sp. gr. 0.928, 0.98, and 1.012 respectively are given.

Still for the fractional distillation of volatile liquids [e.g., crude benzol]. Sadler and Co., Ltd., Middlesbrough, and J. Bellerby, North Ormesby, Yorks. Eng. Pat. 105,395, Apr. 11, 1916. (Appl. No. 5306 of 1916.)

CRUDE benzol is passed from a tank through a closed vessel containing a preheating coil, to the top of the main still. The still comprises a casing containing superposed horizontal shelves with overflow pipes at opposite sides alternately, so that the liquid flows downward in a sinuous path. Steam enters at the bottom and passes upward through the shelves by means of short vertical pipes covered by hoods. The steam and distillate are passed through the preheating coil and partly condensed, the liquid (crude toluol) being separated and the vapour passing to a condenser from which it issues as strong benzol. The residue from the still passes to a "stripping still" containing creosote heated above 100° C. by a steam coil. The water and volatile products in the residue are evaporated and passed to a condenser and the stripped creosote remains. The crude benzol is thus separated into four fractions.—W. F. F.

1,5-Dihydroxynaphthalenedicarboxylic acid; Manufacture of —. F. von Ifemmelmayr, Graz, Austria. Ger. Pat. 296,501, Mar. 4, 1915. Addition to Ger. Pat. 296,035.

SOLID bicarbonates are allowed to act on 1,5-dihydroxynaphthalene in presence of an indifferent solvent or medium, e.g., trichlorobenzene or nitrobenzene.—F. W. A.

IV.—COLOURING MATTERS AND DYES.

Dyestuffs; Fastness of —. Standards and processes established by the "Echtheitskommission." Second Report to the Verein deutsch. Chemiker. P. Heermann. Mitt. k. Materialprüf., 1916, 34, 153—156.

CERTAIN standards prescribed in the first report (this J., 1914, 248) have been modified and replaced by the following:—I. *Fastness to light.* (IA.) Fastness of dyed cotton. The sample is exposed together with the dyed standard in a box suspended in the open under glass, one half of the object being covered by paper or cardboard. At the Materialprüfungsamt two exposures are always made, one under glass and one in the open, subject to all atmospheric influences. Dressed goods are faster to light than undressed goods. The type standards are: I. 5% of Chicago Blue 6 B (424) dyed at the boil with two additions of Glauber's salt. II. 0.8% of Methylene Blue B.G. (659) dyed cold to warm with 2% of acetic acid on a 3% tannin and 1.5% antimony salt mordant. III. 1% of Indoin Blue on cotton mordanted as in II. IV. 20% of Kroyen Violet, with 1.5 times its weight of crystallised sodium sulphide, dyed at the boil with the addition of soda-ash and salt. V. 2.5% of Benzo Light Red 8 B.L. dyed as in I. VI. 10% of Hydron Blue G., 20% paste (748) dyed at 60° C. with caustic soda and 5% of hydrosulphite. VII. 8% of Sulphur Black T., extra (720) dyed as in IV. VIII. 25% of Indanthrene Blue G.C. paste, dyed with 6.25% of hydrosulphite and caustic soda. (IB) Fastness of dyed wool. The tests are carried out in the same way as for cotton; in the case of piece goods the exposure should be made both under glass and in the open. The type standards are: I. 3% of Indigotin 1A, powder (877) dyed at the

boil with 10% of Glauber's salt and tartar. II. 1.5% of Ponceau R.R. (82), dyed in the same way. III. 2.75% of Amarant (168). IV. 4.5% of Azo Acid Red B. (64). V. 5% of Acid Violet 4 R.N. (B.A.S.F.), with Glauber's salt and acetic acid, from 40° C. to the boil, finished at the boil with sulphuric acid. VI. 2.5% of Diamine Fast Red F. (343), after-chromed. VII. 4% of Anthraquinone Green G.X.N. (861) dyed as in V. VIII. Indigo (874) dyed to a shade equivalent to 2.4% of Sulphocyanin G.R. extra (257); or 7% of Naphthol Green B. (4) dyed with 10% of Glauber's salt and tartar, beginning at 50° C. and finishing at the boil for one hour. 2. *Fastness to kier-boiling of dyed cotton.* Two tests are made: (A) 5 grms. of the dyed sample is intermingled with an equal weight of bleached cotton and the mixture boiled with 10 times its weight of liquor to which has been added 10% of caustic soda lye of 40° B. (sp. gr. 1.357) calculated on the weight of material, for 6 hours at constant volume. (B) The treatment is repeated as under A with the addition of 1% of "Ludigol" on the weight of the material. Standards: I. The shade is distinctly paler after both treatments and the white cotton somewhat stained. III. The shade is appreciably paler after both treatments but the white cotton shows no more than a trace of stain. In the same class are included cases where the shade becomes paler, when treated as under A and the white cotton is stained, but when treated by the B process the white cotton is not stained. V. The dyed cotton under both treatments remains entirely unchanged and the white cotton shows no more than the slightest trace of a stain. Types: I. Normal Paranitraniline Red dyeing, boiled with soap after development. III. Indigo dyeing to the same depth as 3% Diamine Fast Blue F.F.B.; or 10% Indanthrene Yellow G. paste (849) boiled with soap after dyeing. V. Normal Turkey Red (Old Red) dyeing. *Fastness to decatising of dyed wool.* Three tests are applied: (A) The sample is rolled up with the usual material on a decatising cylinder in six layers uniformly and firmly, or in the case of small samples a layer of decatising cloth is wound on first; three further layers are wound on and the whole tied up. The material is steamed for 10 minutes counting from the time when the steam begins to issue through the cloth; it is then allowed to stand for 5 mins. and unwound. (B) The prepared cylinder is steamed for 5 mins. in a closed vessel under 1 atm. pressure. (C) It is steamed for 10 mins. under 2½ atm. pressure. Standards: I. Under treatment A, a fairly strong change in shade. II. Under treatment A, no change in shade. III. Under treatment B, fairly strong change. IV. No change. V. Under treatment C no change. Types: I. 2% of Thioflavin T. (642) dyed at 50° C. for ½ hour. II. 2% of Sulphocyanin G.R. extra (257) dyed as under 14 V. (*loc. cit.*). III. 2% of Sulphocyanin. IV. 2% of Crocein A.Z. (255) dyed as under 7B V. (*loc. cit.*) V. 9% of Naphthol Black 6 B. (269) with 10% of tartar, beginning at 40° C., finishing at the boil for one hour.—J. F. B.

Benzanthrone and its derivatives; A new synthesis of— A. Schaarschmidt. Ber., 1917, 50, 294–303.

The anhydride of 1-phenyl-2,3-naphthalenedicarboxylic acid on treating with aluminium chloride in presence of an aromatic hydrocarbon, is converted into 3,4-benzofluorenone-1-carboxylic acid, which on distillation yields 3,4-benzofluorenone. The latter on fusing with caustic potash gives a product which on warming with concentrated sulphuric acid yields benzanthrone by the migration of a carbonyl group from the 2 to the 8 position in the naphthalene ring. 1-Phenyl-2,3-naphthalenedicarboxylic acid on

treatment with excess of concentrated sulphuric acid in the cold, or on treatment with phosphorus pentachloride in benzene solution and treatment of the acid chloride thus produced with aluminium chloride in carbon bisulphide solution, is converted into benzanthronecarboxylic acid, which forms deep yellow needles, m. pt. 317° C. When 1-phenyl-2,3-naphthalenedicarboxylic acid or benzanthronecarboxylic acid is heated to boiling with phosphorus pentachloride in benzene solution and the product subsequently treated with aluminium chloride, benzoylbenzanthrone, m. pt. 206° C., is formed. 1-Phenyl-2,3-naphthalenedicarboxylic acid on bromination with bromine and glacial acetic acid yields a mono-bromo derivative, m. pt. 282° C., which can similarly be converted into monobromobenzoylbenzanthrone, m. pt. 212° C. —T. C.

PATENTS.

Dyestuffs soluble in sodium sulphide, alkalis, and water; Process for preparing— Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 296,169, Oct. 19, 1913. Addition to Ger. Pat. 264,041 (this J., 1913, 1005; see also Ger. Pat. 268,891, this J., 1914, 247).

THE dyestuffs obtained as described in the original patent are treated with sulphuric acid, oleum, or chlorosulphonic acid, of such concentration, for such time, and at such temperatures, as will yield derivatives giving soluble alkali salts. The resulting products, which must be regarded as sulphonic acids, have a strong affinity for fibres in a sodium sulphide bath. They differ from the dyestuffs of the original patent in being soluble, without previous reduction, in water, dilute alkalis, or alkali sulphides.—C. A. M.

Polychloro substitution products of N-dihydro-1,2,2',1'-anthraquinonocazine [Indanthrene]; Process of preparing— Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 296,841, June 3, 1914.

INDANTHRENE is suspended in an inert organic liquid and treated with chlorine in excess at temperatures not materially exceeding 40° C. The products, and especially the tri- and tetrachloro substitution derivatives, are characterised by their brightness of shade and resistance to the action of chlorine.—C. A. M.

Chlorine derivative of N-dihydro-1,2,2',1'-anthraquinonocazine [Indanthrene]; Process of preparing a— Chem. Fabr. Griesheim-Elektron. Ger. Pat. 296,192, Aug. 10, 1915.

INDANTHRENE is treated with sulphur chloride in an inert medium at temperatures below 100° C. The resulting dichloro-derivative is materially faster to chlorine than Indanthrene Blue G.C.D., and nearly as fast as Indanthrene Blue G.C. The product is in a finely divided state and is suitable for the manufacture of bright-coloured pigments.—C. A. M.

Acid monoazo-dyestuffs for wool; Process of preparing— Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 296,961, May 5, 1914

DIAZOTISED N-alkylacyl- or N-arylacylphenylenediamines or their derivatives, in which the acyl group is derived from an aromatic acid or its ring-substitution products, are combined with pyrazolone- or methylketosulphonic acids, hydroxynaphthalenesulphonic acids, or acylperiaminohydroxynaphthalenesulphonic acids. The resulting products dye wool from acid baths level yellow to bluish-red and brown shades, fast to milling.—C. A. M.

Monoazo dyestuffs suitable for the manufacture of pigments; Process of preparing—, Badische Anilin und Soda Fabrik, Ger. Pat. 296,391, Aug. 7, 1914.

THE diazo compound of 1-aminoanthraquinone is combined with 1-benzoylamino-7-hydroxynaphthalene, or its derivatives substituted in the benzoyl nucleus, with or without the addition of Turkey-red oil or a similar agent, and in the presence or absence of substrata. Bright-red pigments are thus obtained, which are insoluble in water and in oil, are not affected by alcohol or lime, and are remarkably fast to light.—C. A. M.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

[Paper.] *Proper order of adding furnish (colour and size) to beaters*. A. E. Sunderland, Tech. Assoc. Pulp and Paper Industry, Paper-Making, 1917, 36, 145—149.

IN the sizing of undyed pulp it is usual to add first the rosin size and later the alum; this order is based on the observation that the colloid, on account of its low surface tension, if added first, quickly penetrates the pulp-mass and precipitation by the alum then takes place in and about the fibre cells. In the case of pulps dyed with soluble dyestuffs more complex considerations come into play, because of the reactions between the dyestuffs on the one hand and the fibre, rosin size, and alum on the other. These reactions vary according to the nature of the dyestuff. A series of experiments is described with mixtures consisting of 10 grms. of sulphite pulp in 500 c.c. of water, when treated with 1% of dyestuff, 5% of rosin in the form of size, and 5% of alum, calculated on the weight of the pulp. The ingredients were added to the pulp in six different orders. (1) Colour, size, alum. When the colour is added the pulp absorbs about 75% of the dyestuff; the size forms a precipitate with the colour in the liquor and then begins to strip the colour from the pulp; the alum in most cases reacts with the excess of size, then decomposes the colour-resinate, liberating the colour, which is again absorbed by the pulp. (2) Colour, alum, size. The pulp absorbs 75% of the colour; alum produces no change; the size reacts with the alum. If alum is in excess the colour is unaffected, but if the size is in excess it reacts with the colour in the liquor and then begins to strip the colour from the pulp. (3) Size, alum, colour. The reaction of the size and alum forms a milky precipitate which acts as a resist to the colour; if alum is in excess the colour is slowly absorbed but if the size is in excess the pulp is less deeply dyed. (4) Size, colour, alum. The size reacts with the colour at once and the pulp is only slightly dyed; on the addition of alum the colour resinate is slowly decomposed and the pulp gradually absorbs the colour. (5) Alum, colour, size. Same as (2). (6) Alum, size, colour. Same as (3). The best results are obtained by adding colour first, then alum, and lastly size, as in (2), but too much alum causes a too deeply coloured effluent and the quantity should be considerably less than 5%. This applies to basic dyestuffs. With less alum, less size may be used and any deficiency in the retention of the fine precipitate may be counteracted by the subsequent addition of salt, which induces flocculation. Similar considerations apply to acid and substantive dyestuffs, but more than 5% of alum may be required.—J. F. B.

Paper-yarn sacks for sand; Waterproofing—, L. Cassella and Co., Chem.-Zentr., 1917, 44, Rep., 56.

THE various methods employed for impregnating

paper yarn sacking so as to increase its tensile strength when wet were examined. The best results were obtained by first impregnating the dry paper at 50° C. with a solution containing 80 grms. of glue, 1.5 grms. of tannin, and 1.5 grms. water-glass at 37° B. (sp. gr. 1.345) and then drying it. Strips 30 cm. × 5 cm. gave the following values for the tensile strengths of the warps, the figures in the brackets representing the values for the wefts:—

	Untreated*	Treated.
	kilos.	kilos.
Dry material	34.4 (37.1)	45.7 (44.5)
After 24 hours' soaking in water ..	26.4 (23.7)	34.2 (30.8)
After re-drying	41.2 (37.4)	45.2 (41.1)

The next best results were obtained by first treating the material with cold basic aluminium formate at 6° B. (sp. gr. 1.013) and drying, then at 50° C. with a solution containing 80 grms. of glue per litre, and then repeating the treatment with basic material. The use of mixtures of soap and glue was not satisfactory. Drying between each treatment increased the tensile strength of the product.—A. B. S.

Paper tubes; Experiments with—, M. Rudeloff, Mitt. k. Materialprüf., 1916, 34, 61—77.

TESTS were made with tubes prepared by the process of A. von Valois by rolling paper to the desired diameter and thickness of wall, fastening with a suitable adhesive, and coating. The tubes are intended to serve as pipes for gas and water. The specific resistance to direct hydraulic bursting pressure calculated according to the formula, $\frac{pd}{2W}$, averaged 360 kilos. per sq. cm., where p is the bursting pressure in atmos., d the internal diam., and W the thickness of the wall. The tubes were not appreciably affected by the prolonged action of coal gas, and some which had stood full of water for several weeks showed no perceptible swelling or loss of resistance. These paper tubes are only $\frac{1}{10}$ to $\frac{1}{15}$ the weight of lead pipes and resist 3—4 times the pressure for equal diameters. The joints of the paper pipes consist of tube sections slipped over the two ends to be united, the annular space being packed with a suitable composition. The jointed pipes burst at a considerably lower pressure than the single pipes and in some cases gave way at the joints. Tests for resistance to external pressure showed an average of 27.8 atmos., which is regarded as sufficient resistance to the pressure of the earth, provided the material did not become softened in course of time. Another set of trials was made with "Pertinax" tubes made from paper impregnated with synthetic resin and rolled under tension; the smallest internal diameter obtainable is 5 mm. Tensile tests were made with strips cut from the tubes, both air-dry and after steeping in water; the absorption of water caused a loss of strength of 22—35%, but increased the elongation on breaking; the modulus of elasticity was lowered by steeping. It appeared, however, that the absorption of water took place largely through the unprotected cut edges of the strips and to this extent the tests are not regarded as conclusive. Another make of paper tube was tested for absorption of water when the closed tube was allowed to stand full of water; the absorption was particularly large in the first hour and had not reached its limit after 282 hours; only the inner surface of the tube was softened, the outside not being visibly affected. For use with water, the suitability of paper tubes cannot be regarded as established, but further investigations are necessary before a definite judgment can be pronounced.

The "Pertinax" tubes of small diameter should give good results for oil conduits in view of the well-known resistance of synthetic resins to oil. Bending tests with paper tubes have shown that they cannot be regarded as suitable for constructional purposes. The tensile strength of 10—18 kilos. per sq. cm. with a low specific gravity (1.2) is sufficient, but the compression strength (4.6 kilos. per sq. cm.) is too small and the extremely low modulus of elasticity would produce distortions of the structure even under very moderate stresses.

Determination of resin in rosin size. Heuser. See XIII.

Trimethylglucose from cellulose. Denham and Woodhouse. See XVII.

PATENTS.

Wool and other fibrous material; Machines for washing —. W. R. Kay, Cottingham, Yorks. Eng. Pat. 105,463, June 23, 1916. (Appl. No. 8825 of 1916.)

In a washing machine consisting of a bowl and guiding trough for the goods, the guiding trough is constructed with perforated bottom and sides so that the liquor may circulate freely between the inside of the trough containing the goods and the main bowl. The guiding trough may be situated centrally in the outer bowl, or side-troughs or gutters may be used with perforated sides and communicating with the base of the bowl. Agitating or circulating devices are provided in the trough so as to give the liquor a downward and longitudinal thrust, followed by an upward movement. Suitable devices consist of inverted V-shaped agitators mounted on longitudinal bars (see Eng. Pat. 28,192 of 1910; this J., 1911, 1307).

—J. F. B.

Artificial silk; Funnels or thread guides for use in machines for the manufacture of — and apparatus to be used for same. Courtaulds, Ltd., London, and J. Clayton, Coventry. Eng. Pat. 104,225, Mar. 1, 1916. (Appl. No. 3120 of 1916.)

THE funnel or thread guide through which the thread passes from the coagulating bath into the rotating spinning box is provided with a ferrule or sleeve surrounding the part of the funnel which is to be supported in the fitting or bearing of the machine. The ferrule is applied at a predetermined distance from the lower end of the funnel and so that the upper and lower ends of the tubular part of the funnel are in line with the longitudinal axis of the ferrule. The ferrule is adjusted on the funnel by supporting the latter between two conical bearings on a vertical stand which also carries the ferrule at an intermediate point, the centres of the supports and axis of the ferrule being in one line, and when the parts are properly adjusted and secured by a clip, pitch is run into the space between the funnel and ferrule to make a permanent mounting.—J. F. B.

Adhesive coatings; Method of preparing — and applying them to fabrics without the use of solvents. J. Meade, Stoughton, Mass. U.S. Pat. 1,222,967, Apr. 17, 1917. Date of appl., Mar. 16, 1916.

A GUM and a wax are ground together and mixed at a temperature at least as high as that at which the mixture becomes plastic, e.g., 170° F. (77° C.); the mixture is tempered by immersion in a liquid heated to a higher temperature, e.g., 210° F. (99° C.) and is then spread on the fabric at a still higher temperature, e.g., 212°—215° F. (100°—102° C.).—J. F. B.

Cellulose preparations; Process for purifying and improving —. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Ger. Pat. 296,053, June 17, 1914.

THE material in a swollen condition is subjected to the action of an electric current between diaphragms; the material may be transported continuously between the electrodes partitioned off by diaphragms. The process is applicable to products derived from viscose, cellulose acetate, formate, or nitrate. The treatment is intended to counteract the adsorption of traces of catalyst which makes these products unstable.—J. F. B.

Paper; New method of sizing —. R. W. Sindall and W. Bacon, London. Eng. Pat. 105,444, May 23, 1916. (Appl. No. 7320 of 1916.)

PAPER is immersed first in a solution of gelatin which may contain soap, starch, gum, or resins, but no alum or aluminium sulphate, and subsequently in a solution of gelatin containing alum or aluminium sulphate. The first solution may safely be heated to a higher temperature than is usually employed in sizing paper and better penetration thus obtained.—J. F. B.

Paper-size and process of making same. J. A. De Cew, Montreal, Canada. U.S. Pat. 1,223,480, Apr. 24, 1917. Date of appl., Feb. 25, 1914.

THE cold size solution contains a non-decomposing ammonium resinate, free ammonium hydrate, and water, without the presence of free rosin; the solution is made from a cold thick size by forcing the latter by means of pressure into a cold aqueous solution.—J. F. B.

Sulphite cellulose; Apparatus for the extraction of hydrocarbons, etc., especially cymol, which arise in the manufacture of —. P. G. Enger, Skotselven, Norway. U.S. Pat. 1,223,158, Apr. 17, 1917. Date of appl., Mar. 9, 1916.

In an apparatus for separating oily and resinous extractives from pulp, several tanks are provided, one of the tanks having an inlet connected with the top outlet of the digester and an outlet near the top of the tank leading to an inlet near the bottom of the second tank. The second tank has an outlet near the bottom, diametrically opposite the inlet, leading to an inlet in a third tank at a slightly higher level than the outlet in the second tank, and a return pipe is provided from the third tank to the digester.—J. F. B.

Packing rings [from viscose]. Chem. Fabr. von Heyden A.-G. Ger. Pat. 296,405, Apr. 14, 1916.

CELLULOSE obtained by the decomposition of viscose is treated with a hygroscopic substance such as calcium chloride, which counteracts its tendency to shrink.—F. W. A.

[Paper;] Paraffin coating machine [for —]. E. H. Vavra, Chicago, U.S.A. Eng. Pat. 105,827, June 14, 1916. (Appl. No. 8386 of 1916.)

Artificial-silk machines; Thread guide for —. Device to be employed in making funnels, or thread-guides, for use in machines for the manufacture of artificial silk. J. Clayton, Coventry, Assignor to Courtaulds, Ltd., London. U.S. Pats. 1,224,070 and 1,224,071, Apr. 24, 1917. Dates of appl., Apr. 18 and Aug. 17, 1916.

Production of charcoal [from sulphite-cellulose waste-tyes]. Eng. Pat. 102,608. See III.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Fastness of dyestuffs. Standards and processes established by the "Echtheitskommission." Heermann. See IV.

PATENTS.

Textile fibres: Manufacture [treatment before bleaching] of —. E. T. J. Watremez, Brussels. Eng. Pat. 6195, Apr. 26, 1915. Under Int. Conv., June 16, 1914.

To facilitate subsequent bleaching, vegetable fibres are immersed in a bath containing alkali and a solution obtained by boiling for several hours a solution of zinc or other alkali-soluble metal in concentrated caustic soda or sodium carbonate solution mixed with a soluble oil, e.g., sodium or ammonium sulphuricinate, and then filtering. The bath is raised to the boil for the necessary time, the metallic salts combined with the fibre are removed by means of a mixture of sulphuric and sulphurous acids, and the material is rinsed, or it may be boiled in an alkali bath, and then passed through acid before being rinsed.—F. W. A.

Dyes on the fibre: Production of aniline —. J. F. Moscey and E. M'Cardell, Manchester. Eng. Pat. 105,349, Feb. 9, 1916. (Appl. No. 1898 of 1916.)

BROWN and similar shades on textile fibres or fabrics are obtained by oxidising salts of aniline or its homologues mixed with an aromatic hydroxy-compound containing no nitro-, nitroso-, or amino-groups, e.g., a phenol. *Example.* The fabric is impregnated with a hot solution of a mixture of a 10% aniline solution and a 10% phenol solution, and developed in a bath containing 22 lb. of hydrochloric acid (32 Tw., sp. gr. 1.16) and 14 lb. of sodium bichromate in 200 gallons of water.—F. W. A.

Dyeing. H. C. Miller, London, and H. A. Irlam, Mill Hill. Eng. Pat. 105,353, Apr. 10, 1916. (Appl. No. 3213 of 1916.)

IN dyeing wool, leather, silk, etc., with the dyes obtained by treating gums or gum-resins from plants of the *Xanthorrhoea* genus with sulphuric acid (Eng. Pat. 101,353 of 1916; this J., 1917, 500), more permanent or fast colours of varying shades or tones are obtained by adding a chromium compound, such as a bichromate, or other oxidising agent to the dye-bath, or by pre-treating or after-treating the material to be dyed with such a reagent.—F. W. A.

Dyeing yarns and slubbings: Machines for —. S. S. Partridge, Kidderminster. Eng. Pat. 105,415, May 24, 1916. (Appl. No. 7379 of 1916.)

IN a machine for dyeing yarns and slubbings, a hank-carrying frame in addition to having vertical reciprocating movement, produced by means of mechanism as described in Eng. Pats. 8370 of 1901 and 3114 of 1911 (this J., 1905, 513; 1915, 75) is given a horizontal reciprocating movement so as to carry non-rotating horizontal hank-carrying poles immersed in the vat laterally to and fro. Perfect stirring and circulation of the dyeing liquor through the hanks is thereby effected without providing any additional stirring mechanism in the vat.—F. W. A.

Dyeings on cotton and similar fibres: Production of fast —. Farlow, vorm. Meister, Lucius, and Brüning. Ger. Pat. 296,141, May 31, 1914.

AZO-DYESTUFFS containing one or more molecules of an aminarylpyrazolone or derivatives with a free amino-group in the end position, other than the dyestuffs claimed in Ger. Pat. 289,350 (see U.S. Pat. 1,147,803; this J., 1915, 900), are treated on the fibre with formaldehyde or a substance yielding formaldehyde in warm, acid solution, to improve their fastness to washing.—F. W. A.

Dyeings: Production of —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 296,112, Feb. 10, 1916.

DI- β -NAPHTHYL-4,4'-DIAMINODIPHENYLAMINESULPHONIC acids and their substitution products, containing a hydroxyl group in the naphthalene nucleus, are oxidised on vegetable fibre. The fibre is dyed in neutral or alkaline solution, with or without addition of salts, and the oxidation is carried out in the usual manner by means of chromic acid or its salts, or with copper salts in presence of organic acids, e.g. formic or acetic acid. The shades produced, generally grey on cotton, are very fast to light.—F. W. A.

Calf's-skin in the hair: Dyeing of tanned — and of goods produced therefrom. R. Knote, Furth, Austria. Ger. Pat. 296,394, May 21, 1916.

AFTER degreasing with sodium carbonate solution, the skins are treated with potassium carbonate and caustic potash solution, the surface exposed to air, treated with alum or aluminium sulphate solution, and afterwards with highly concentrated hydrogen peroxide, dried, and then dyed with Indigo Extract or Indigo Carmine by brushing on or by immersion. For white-haired calf's-skin a bottoming of walnut or gallnut extract is used. In order to obtain the desired tone, the dyed skins are treated with salts such as copper sulphate, ferrous sulphate, or potassium bichromate.—F. W. A.

Azo dyestuffs on the fibre: Production of —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 296,559, Oct. 10, 1914.

FABRIC padded with 2,3-hydroxynaphthoyl-aminonaphtholsulphonic acids or their derivatives dissolved in cold, dilute sodium carbonate solution, is treated with unsulphonated diazo-compounds. Clear yellow, red, blue to black dyeings very fast to boiling are obtained.—F. W. A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphates of sodium: Acid and neutral —. P. Pascal. Comptes rend., 1917, 164, 628–630.

THE author has studied the system sodium sulphate-sulphuric acid-water, at temperatures between -45° and 210° C., defining the conditions of existence in contact with solution of the following solid phases:—Ice, Na_2SO_4 , $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$, $\text{Na}_2\text{SO}_4 \cdot \text{NaHSO}_4$, $\text{NaHSO}_4 \cdot \text{H}_2\text{O}$, NaHSO_4 , $\text{NaHSO}_4 \cdot \text{H}_2\text{SO}_4 \cdot 1.5\text{H}_2\text{O}$, and $\text{NaHSO}_4 \cdot \text{H}_2\text{SO}_4$. The conditions of existence of the hydrate, $\text{Na}_2\text{SO}_4 \cdot 7\text{H}_2\text{O}$, are less clearly defined, while some evidence was obtained of the existence of the compounds, $\text{Na}_2\text{SO}_4 \cdot 2\text{NaHSO}_4$ and $\text{H}_2\text{SO}_4 \cdot 2\text{NaHSO}_4$. From the data afforded by his diagram, the author proceeds to the discussion of the results of cooling nitre-cake, and of crystallising solutions of bisulphate in water. By pouring fused nitre-cake into water and allowing to cool so that crystals of NaHSO_4 , Na_2SO_4 separate, it would be possible to obtain a mother liquor richer in free acid and with a relatively low content of normal sulphate.
—W. H. P.

Potash from Nebraska lakes. R. P. Crawford. Eng. and Min. J., 1917, 103, 777—778.

THE extraction of potash and soda from the more saline of the sand-hill lakes of Nebraska is at present conducted by the Potash Products Co. at Hoffland (now shipping about 1500 tons per month of the crude salts), the Nebraska Potash Works Co. and the American Potash Co. at Antioch, and the Hord Alkali Products Co. and the Palmer Alkali Co. at Lakeside. The brine worked occurs beneath a thin layer of hardpan at the bottom of the lakes, the salinity of the upper water being usually too low for profitable extraction. By means of electrical pumps, provided with filters to exclude sand, the brine is pumped through long pipe-lines to the evaporating plant consisting of vacuum kettles, in which the solution is concentrated to a yellow liquid, and rotary dryers in which the latter is evaporated until crystallisation occurs. The mixed salts thus obtained are marketed in the crude state; they consist of sulphate, carbonate, bicarbonate, and chloride of sodium and carbonate and sulphate of potassium, the Potash Products Co.'s salts containing H_2O 2.14, K_2O 27.35, Na_2O 28.39, CO_2 22.14, SO_3 16.77, and Cl 2.02% according to one analysis.

—W. E. F. P.

Ferrous sulphide; Heat of formation of —. N. Parravano and P. de Cesaris. Gazz. Chim. Ital., 1917, 47, I., 144—149.

PURE iron was obtained by reducing ferric oxide (derived from pure ferric ammonium sulphate) by means of hydrogen at $700^\circ C$. It was mixed with sulphur, which had been purified by three crystallisations from carbon bisulphide, in equimolecular proportions, and the mixture was ignited in a calorimetric bomb by means of an electrically heated platinum wire. The average results of six determinations were 26.2 cal. per grm. of ferrous sulphide formed or 23,070 per grm.-mol.—C. A. M.

Hydrogels of silica; Behaviour of — at low temperatures. B. L. Vanzetti. Gazz. Chim. Ital., 1917, 47, I., 167—189. (See also this J., 1916, 837.)

EXPOSURE to low temperatures has practically no effect upon silicic acid coagulums and hydrogels. The final composition of the coagulums depends not only on the initial composition and age of the mixture, but also upon the degree of moisture in the air during the process of rapid drying. The final molecular ratio $[H_2O]:[SiO_2]$ is frequently less than unity when the hydrogel is dried in the air, especially in the case of coagulums rich in silica. The variations in this ratio are too great to support the view that hydrates of silica are present. The absorption theory of Van Bemmelen and the theory of the granular constitution of the coagulums (this J., 1911, 1056; 1912, 82) appear to give a satisfactory explanation of all the transformations which the colloidal systems of water-silica can undergo.—C. Hydrogen sulphide and hydrogen cyanide from crude gases; Recovery of —. J. Behrens, Bremen. Ger. Pat. 296,466, Feb. 22, 1916.

THE cooled crude gas is passed over cold charcoal, from which the absorbed hydrogen sulphide and hydrogen cyanide are afterwards liberated by heat, e.g., by means of a current of hot gas or superheated steam. The crude gas may be divided into two portions, of which one is passed over the cold charcoal, whilst the other serves as heating medium to liberate the absorbed gases from the charcoal; the first portion, after one passage over the cold charcoal, is returned to the main stream of crude gas, so that it may be brought into contact with the charcoal a second time. The hydrogen sulphide and hydrogen cyanide liberated from the charcoal are absorbed in water and subsequently recovered separately by fractional evaporation.—F. W. A.

Clay; Refractory properties of —. H. Le Chatelier and F. Bogitch. Comptes rend., 1917, 164, 761—767.

THE authors have heated cubes having sides of 1 cm., under pressure, in a Schloesing's gas-heated furnace. The samples were supported on a block of sintered magnesia with an intervening layer of chromic oxide. The pressure was applied by an iron rod with a 2-in. end-piece made of bauxite burned at $1600^\circ C$. The temperatures were measured by a thermo-couple in contact with the samples. The percentage composition of the clays used was as follows:—

	G.	L.	A.	C.	B.
Alumina	20.0	26.0	26.5	12.6	33.0
Iron oxide	3.4	1.9	3.9	2.4	1.5
Lime	0.8	0.2	2.0	0.0	0.3
Silica, etc. (by diff.)	75.8	71.9	67.6	85.0	65.2

Brick G, of medium quality, burned at $1200^\circ C$, had the following crushing strengths:— 190 kilos. per sq. cm. at $15^\circ C$; 185 kilos. at 600° ; 200 kilos. at 950° , and 180 kilos. at $1080^\circ C$. At temperatures below $1100^\circ C$, the bricks broke suddenly and completely, but at higher ones, they became more plastic and underwent severe deformation before breaking. Thus, at $1300^\circ C$, 65 kilos. per sq. cm. and at $1350^\circ C$, 20 kilos per sq. cm. effected in 20 secs. a deformation of more than 5% of the thickness of the original bricks. The strength of these bricks declined very rapidly at temperatures above $1200^\circ C$. When the tem-

perature of brick G was raised from 1200° to 1398° C. in 11 min., the brick being under a pressure of 10 kilos. per sq. cm., the deformation was 48%, while the brick heated to 1415° C. in 11 min. showed a deformation of 73%, with a pressure of only 1 kilo. per sq. cm. The intervals between the temperatures giving the same amount of deformation at different pressures were less than would be anticipated, and did not exceed 50° when the pressure was increased ten-fold. When brick L was heated under pressure there were intervals of nearly 50° between the temperatures at which the same amount of deformation was produced in bricks burnt at 1200° C. and at 1430° C. respectively.

Small bricks of washed kaolin, burnt at 1200° C., when heated under a pressure of 10 kilos. per sq. cm., showed a deformation of 5.7% at 1400° and 21.7% at 1500° C. Under similar conditions, clay B (which is used for steel crucibles) showed a deformation of 9% at 1460° C.

The quality of bricks may be judged by determining the temperature at which the deformation is 20% under a pressure of 10 kilos. per sq. cm. exercised during one minute.

For the materials tested by the authors this temperature lies between 1350° and 1500° C. The high pressure mentioned was chosen so as to limit the experimental errors, but on prolonged heating, bricks will suffer deformation under much smaller pressures; thus, with a pressure of only 1 kilo. per sq. cm., 20% deformation occurs at 1250°—1350° C. Freshly made bricks are composed of a mixture of kaolinite and quartz; after burning at 1300°—1500° C. for a sufficiently long time, they consist of a mixture of sillimanite, tridymite, and some unconverted material. Thus, brick A from a furnace at Assailly was in a state of equilibrium corresponding to 1000°—1500° C. On heating such a brick to 1600° C. and then cooling it rapidly, part of it may be seen to have been fused. Hence, bricks, like alloys and mixtures of salts, remain solid up to a certain eutectic temperature, at which one constituent fuses completely and the second partially. If the temperature is still further increased, the fusion progresses still further. In the case of silicious compounds, the phenomenon is complicated by the viscosity of the molten material which retards the establishment of an equilibrium; hence the difficulty of determining the reversible fusing and solidifying point of a silica-alumina eutectic mixture. The authors heated a cube of fused silica with 1 cm. sides under a constant pressure of 10 kilos. The mass began to yield at 1300° C. and 10 min. later, at 1400°, the deformation amounted to 40%. They conclude that below 1500° C. vitreous silica is not sufficiently fluid to permit rapid changes towards a state of equilibrium; hence our ignorance of the nature of the fusibility graph of mixtures of tridymite and sillimanite. On the other hand, bricks used in industrial furnaces have been burned at such a temperature and for so long a time that they have reached an equilibrium and are composed of sillimanite and tridymite.

It is suggested that when kaolinite is dehydrated, it is decomposed into amorphous silica and alumina. The silica softens as the temperature rises and combines with the various bases, including alumina. Ordinary glass is quite soft at 800° C. In the fusion of bricks, this gradual fusing of the silica is seen and not the reciprocal solution of the tridymite and sillimanite. On the other hand, any quartzose silica present in a clay does not become amorphous, but is converted into cristobalite or is dissolved in the glassy matrix. This incipient fusion of bricks at the expense of the amorphous silica is followed by crystallisation of the silica in the form of tridymite, and normal fusion can only occur at a still higher temperature. If a brick is heated sufficiently slowly for the various trans-

formations to be completed, it will pass through two zones of fusibility, separated by an interval of recrystallisation. A well-burned brick does not show the first zone.—A. B. S.

Glass-melting pot. E. A. Gillinder, Philadelphia, Pa. U.S. Pat. 1,223,959, Apr. 21, 1917. Date of appl., Sept. 17, 1915.

A GLASS-MELTING pot, closed at the top, except for a feed-inlet, has a discharge passage in the lower part of its side leading to a well which forms an extension of the pot. The floor of the pot is inclined towards the well.—A. B. S.

Clay: Process and apparatus for refining.—S. A. W. Okell, East Orange, N. J., Assignor to Industrial Chemical Co., New York, N.Y. U.S. Pat. 1,222,979, Apr. 17, 1917. Date of appl., July 6, 1916.

RAW clay is suspended in water to the extent of about 10% and fed continuously into the bottom of a drum wherein it is given a powerful centrifugal motion by means of paddles attached to a vertical shaft. The heavier particles of grit, etc., separate and are removed in suspension from the lower part of the drum. The purified clay is removed through a vertical tube, with a side outlet, attached to the top of the drum.—A. B. S.

Ceramic kiln. A. L. Stevens, Chicago, Ill. U.S. Pat. 1,223,440, Apr. 21, 1915. Date of appl., Sep. 10, 1912.

A REGENERATOR communicates with each unit of a continuous series of bag walls and flues extending the full length of each side of the kiln, and is also provided with an inlet for fresh air. Hot air or gas from the regenerators passes alternately through the flues on opposite sides of the kiln and is discharged through flues on the opposite side, into the regenerator communicating with the latter.—A. B. S.

Spraying ceramic and other articles: Method of affording protection to workmen during the operation of.—Sanitary tile-spraying chamber. H. D. Lillibridge, Zanesville, Ohio, Assignor to American Encaustic Tiling Co., Ltd., New York. U.S. Pats. (A) 1,223,809 and (B) 1,223,810, Apr. 21, 1917. Date of appl., July 28, 1913.

(A) THE spraying is conducted in a closed chamber and any surplus material is intercepted by an absorbent medium such as a curtain or film of flowing liquid towards which the spray is directed. The medium prevents the rebound of the sprayed matter. (B) The apparatus consists of a chamber fitted with a spray, with means for circulating air, with an absorbent curtain of flowing liquid to receive surplus matter, and with means for withdrawing air from near the top of this curtain so that the work may be done without danger of inhaling the sprayed material.—A. B. S.

Muffle kiln for enamels. E. Schröder, Berlin, Ger. Pat. 296,457, Oct. 31, 1915.

IN order to effect a more uniform distribution of the heat, a muffle kiln for enamels is provided with a deep, narrow circumferential flue extending beneath it. The sole of the kiln is built with two or more steps, and part of the kiln wall is constructed of a material (e.g., carborundum) of lower thermal conductivity than fireclay. By this means, the flames play on each support for only a short time and the heat is not so severe as usual. Even if a support is built of poor materials and cracks, it cannot choke the flue. Further advantages are that the flue dust does not attack the walls of the kiln so readily and the muffles last longer.

The sole of the muffle may be built of arch bricks and a better distribution of heat secured.

IX.—BUILDING MATERIALS.

Bricks and the like; The properties of — [Proposed standards.] H. Burchartz. Mitt. k. Materialprüf., 1916, 34, 79—152.

In order to arrive at some standard specification for the various types of brick, all the samples tested at the Materialprüfungsamt during the period 1907—1913 according to the standard methods have been grouped, and from the results there has been evolved a series of proposed standard values for each type which should be readily attainable under commercial conditions:—*Volume-weight* in grms. per c.c. (r): for clinker bricks, 1·85; hard-burnt ware, 1·75; building bricks, 1st quality, 1·60. *Specific gravity* (s): clinker, 2·6—2·7; hard-burnt, 2·6—2·7; building bricks, 1st quality, 2·6—2·75. *Specific gravity* decreases very slightly the harder the burning; for instance, average values for the three types were 2·650, 2·660, and 2·680 respectively. It will vary somewhat according to the material, but no brick with a specific gravity below 2·50 is fit for building purposes. *Impermeability* is calculated from the apparent volume-weight and the specific gravity by the formula $1 - \frac{r}{s}$; the proposed standards are

therefore based on the foregoing. *Absorption of water.* The absorptive capacity of bricks varies very largely even for the same sort and it is difficult to lay down any rigid standards; moreover, it has been proved that the capacity for absorption of water bears no direct relationship to the strength. It is only necessary to put forward standards in the case of clinker and hard-burnt bricks which are largely used for conduits and should possess a certain degree of water-tightness. For clinker is suggested an absorption of 5% by weight or 10% by vol., and for hard-burnt, 8% by weight or 16% by vol. *Crushing resistance.* Standards have already been adopted by the German building trade association which, according to the average tests of the Materialprüfungsamt, are by no means too high. These standards prescribe for the crushing resistance, in kilos. per sq. cm., 350 for clinkers, 250 for hard-burnt, 150 for building bricks 1st quality, and not less than 100 for 2nd quality building bricks for use in interiors. The author suggests that the standard for 1st quality building bricks might reasonably be raised to 180. The ratios of crushing strengths when saturated with water and after repeated freezing to the crushing strength of the dry brick are of considerable importance, and it is suggested that the average loss of strength in the saturated condition should not exceed 15% and the loss after freezing should not exceed 25%. Bricks must be free from lime in lump form and finely divided lime should not be present except in harmless quantities. Abrasion tests should be adopted for clinkers which will ensure that they present at least as good resistance to wear as other artificial paving materials.—J. F. B.

Specific heats of various building and insulating materials. M. Kinoshita. Gesundheits-Ing., 1916, 39, 497—503. Z. angew. Chem., 1917, 30, Ref., 65.

Mortar; Mixing — E. Becker, Washington, D.C. U.S. Pat. 1,223,239, Apr. 17, 1917. Date of appl., Feb. 24, 1912.

MORTAR consisting of lime or cement, water, and sand is preserved by adding during the mixing, lead acetate in the proportion of more than 0·5% of the lime or cement. Insoluble salts of lead are formed with substances which would otherwise attack the mortar.—W. F. F.

Artificial stone slab, shingle, and plate, and composition for making same. W. Singer, Passaic, N.J., Assignor to Asbestos Slate Roofing Manufacturing Co., Inc. U.S. Pat. 1,223,834, Apr. 24, 1917. Date of appl., Aug. 20, 1915.

A COMPOSITION for making artificial stone slabs, slungles, plates, and the like, consists of hydraulic cement, fine asbestos fibre, chemically active precipitated anhydrous silica, and about twice the weight of the dry mass of water. The surface of the slabs may be hydrated by steam, and the whole mass is strengthened and hardened by the formation of insoluble silicates on exposure to atmospheric moisture and carbon dioxide.—W. F. F.

Shaft-kilns; Preventing the admission of "false air" into — G. Polysius, Dessau, Ger. Pat. 296,155, Mar. 17, 1916.

THE magnesite, lime, cement-mix, or other material to be burned is charged into the kiln through a succession of auto-feeders arranged one above another, the supply to each being shut off before its exit is fully closed. When a rotary hopper is used, it is fitted with trippers which operate the exit slide of a primary supply hopper; it is automatically closed by springs. By these means, material cannot become jammed between the slide and its frame, thus preventing complete closure and admitting "false air."—A. B. S.

Waterproof cement; Production of —. H. Kunze, and "Anneliese" Portland-Cement- u. Wasserkalkwerke A.-G. Ennigerloh. Ger. Pat. 296,537. Apr. 30, 1914.

Hot cement clinker is mixed with a solid material such as paraffin, which melts and, having a low viscosity, fills up the pores. The grinding mills are fed with a mixture of porous and saturated clinker.

— A. B. S.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Cast iron; Metallurgy of —. A. Stadelcr. *Stahl u. Eisen*, 1916, 36, 935—936, 1031—1039. *Z. angew. Chem.*, 1917, 30, Ref., 13.

EXPERIMENTS are reported on the influence of carbon, silicon, manganese, and phosphorus on the properties of cast iron. The quantity and character of the graphite appear principally to determine the mechanical properties. With grey iron containing 1.5% Si, small quantities of manganese, up to 0.3%, increase the formation of graphite, but a further increase to 2.5% has no influence. Cast irons rich in phosphorus, contrary to existing ideas, may be improved by the presence of 1% of manganese. With a rise in the proportion of graphite, the strength of the iron in tension and bending falls off. This occurs also with increase in the percentage of carbon and silicon, both of which favour the formation of coarse graphite. With increase of phosphorus up to 0.3% and of manganese up to 1%, the strength in tension and bending increase. Phosphorus up to 0.3% and also high graphite content favour bending, while manganese and silicon have the opposite effect. The resistance in the impact test, above all properties, shows the greatest sensitiveness to phosphorus. It diminishes rapidly as the phosphorus content rises until this reaches 0.6%, above which the decrease is inconsiderable. This property brings out the superiority of irons low in phosphorus in a special degree. Silicon and manganese have a similar effect. Hardness falls with a rise in graphite content and is increased by a rise in manganese and phosphorus. As graphite is the constituent which has most bearing on the properties of the iron, it should receive most attention in an examination of the microstructure, especially in exceptional cases.—H. J. H.

Malleable cast iron; Influence of time of heating on quality of —. F. Wüst and E. Leuenberger. *Ferrum*, 1916, 13, 161—172. *Z. angew. Chem.*, 1917, 30, Ref., 41.

EXPERIMENTS on the influence of time of heating on the properties of malleable irons melted either in the cupola or in oil-fired furnaces are recorded. These two sorts of iron differ essentially in the sulphur content, which is much lower when the oil furnace has been used; oil fuel, unlike solid fuel, does not increase the sulphur content of the iron. The mechanical properties of the two sorts of iron are given, before and after the heating to render malleable, and the conclusions drawn are:—

(1) Material cast from an oil furnace, owing to low sulphur content, is much superior to that from a cupola in elongation, contraction, and tensile strength. (2) With increase in time of heating, the tensile strength decreases at first slowly and then rapidly, while elongation and contraction increase. (3) With increased time the toughness and resistance to shock are appreciably increased. (4) Hardness falls off with increased time of heating. (5) With heating the specific gravity

decreases but the time is without much influence. Increased silicon content lowers the specific gravity.—H. J. H.

Niegerland spiegeleisen blast furnace; Investigation of —. H. Thaler. *Berg. u. Hüttenm. Rundsch.*, 1916, 12, 61, 69. *Chem.-Zeit.*, 1917, 41, Rep., 16.

THE manganese content of the slag varies from 9 to 10%. The oxygen ratio of silica to lime is 1.7—2.0. If the silica content rises, more manganese goes into the slag. The quantity of slag influences the yield of manganese. The presence of alumina acts beneficially in reducing the content of silica. Manganese losses diminish with increasing manganese content of the iron. A slow passage through the furnace is desirable. For 20% spiegeleisen the manganese loss amounts to 7—8%.—H. J. H.

Steel; Exfoliation and carbon concentration in the case-hardening of —. E. P. Stenger. *Met. and Chem. Eng.*, 1917, 16, 425—433.

THE splitting or exfoliation of carburised zones of case-hardened steel when subjected to alternating shocks was found to be caused by the difference in the volume change of the core and carburised zone which takes place during the hardening, thus producing a stress between the carburised portion and the unaltered core. Discs of ordinary low-carbon steel, nickel-steel, and chrome-steel were prepared of 1½ in. diam. and from ½ in. to ⅝ in. thick, by cutting from a round bar, and case-hardened by placing in a steel container together with carbonaceous material and heating to various temperatures in a wire resistance furnace. In each experiment, the temperature was measured by a thermo-junction and in most cases was maintained constant until equilibrium was attained and the saturation concentration of carbon at the temperature employed was approached. After cementation, segregation of cementite (Fe_3C), or supersaturated zones, could be observed in some of the discs of all the types of steel used, and the phenomenon was not confined to either high or low temperatures or to those discs which were saturated with carbon. Segregation was found to be due to fluctuations of temperature during the heating and takes place to an abnormal degree in industrial cementation when the furnaces used are fired intermittently. The zones of cementite, which rarely exceed a thickness of 0.002 in. will, when subjected to shock, flake from the case-hardened material in the form of thin plates and give a roughened surface, which is a phenomenon distinct from exfoliation, in which the entire case splits off. After removal of the segregations of cementite by grinding a thin layer of metal from the surface of each specimen, drillings were taken from the disc and a determination made of the carbon by direct combustion, and temperature-concentration curves were drawn by plotting the carbon content against temperature. In each case the amount of carbon was less than and the form of the curve different from that given by the equilibrium relation of the iron-carbon system. These results and the observations made of segregation indicate that cementation does not proceed from the initial formation of cementite on the surface in accordance with the equation $3\text{Fe} + \text{C} = \text{Fe}_3\text{C}$, and subsequent diffusion to the core, but that carbon is transmitted by means of gases into the pores of the iron and an equilibrium established between carbon, carbon monoxide, carbon dioxide, and the solution of iron carbide in iron. Small variations in the impurities in the steels were found not to have a marked effect on the saturation point, but high percentages of nickel and chromium

used a considerable lowering of the saturation curves, due probably to the displacement of the transformation point of the γ -iron which is regarded as necessary to cementation. Determinations of the specific gravity of the carburised steels after heating to 850°C . and quenching in water, showed that while with ordinary steels diminution in density, denoting an expansion, produced by cementation, with nickel steel carburised and hardened metal has a greater density than that of the same material which is hardened but not carburised. Tension and not compression is therefore produced in the carburised zones of case-hardened nickel-steel. If the tension leads to rupture the resulting crack will be normal and not parallel to the surface as in the case of exfoliation. It was found by calculation that, in all cases, the stresses depend not only on the volume changes due to differences in the composition of the core and the case, but also on the relative thickness of core and case and on the coefficient of total linear expansion due to hardening. The stresses can be kept below the safe limit by arranging for a given diameter of material a suitable concentration of carbon and thickness of the carburised layer, and by regulating the subsequent heat treatment. The use of stress formulae in terms of the different determining factors showed that very excessive strains are produced by the high carbon carburised zones in both chrome-steels and low carbon steels.

—J. N. P.

Brass scrap of high copper content; Process for recasting.—Z. Ver. D. Ing., 1916, 60, 801. Z. angew. Chem., 1917, 30, Ref., 28.

For casting scrap of red brass, the necessity for adding considerable quantities of copper and zinc can be avoided by the addition of 0.3% of copper-manganese alloy and 1% of zinc, which oxidise the metal. The metal is heated to 1300°C . under a layer of charcoal and poured into a red hot crucible. The copper-manganese alloy is first stirred in, then the zinc previously heated to 200°C ., and the metal is ready to cast.—H. J. H.

Lead mining and smelting at Galtica, Ont. W. E. Newnam. Amer. Inst. Min. Eng. Eng. and Min. J., 1917, 103, 737—738.

At Galtica, S.-E. Ontario, coarse galena occurs with highly crystalline calcite in a fissure vein up to 10 ft. wide. A small concentrating plant was started in 1916, producing 50% of jig product and 50% of table concentrates, averaging lead 9, zinc 2%, and silver 1.14 oz. per ton. The output being too small for a blast-furnace plant and the distance to the nearest lead smelter too great, a smelter producing 15 tons of metal per day was erected. The concentrate is smelted on a coal-fired 8-ft. mechanical hearth with 2—3% of crushed limestone and 3% of coke breeze. The furnace gases pass through four goose-neck condensers, placed in parallel, into a balloon-shaped suspended flue 300 ft. long, at the end of which a "Sirocco" exhaust fan delivers the gas into 99 cotton bags (18 in. by 30 ft.). The dust is pugged with a little burnt lime and re-smelted. The labour cost (2 men per 8 hour-shift) is \$2.20 per ton of lead, the staff numbering 14 men. The lead pigs are melted, skimmed, and poured. The refined metal is 99.95% pure. The dross is returned to the hearth. 12% of the lead goes into the grey slag, which is at present periodically shipped to a distant smelter.—W. R. S.

Aluminium chips: Melting.—H. W. Gillett and G. M. James. Bull. 108, U.S. Bureau of Mines. 88 pages.

Recovery of scrap aluminium, consisting of borings, sheet clippings or punchings, and sweep-

ings, by melting is subject to considerable loss due to oxidation and failure of the metal globules to coalesce when coated with a film of oxide or dirt. Briquetting is expensive, and can only be practiced in large plants; it would but slightly decrease the melting loss and save time and fuel. Fairly high recoveries are obtained by melting in iron pots, at the lowest possible temperature, while stirring constantly to promote coalescence, but the cost of labour is high. The use of volatile fluxes (sal ammoniac, zinc chloride) while melting down gives a low yield, but they are useful towards the end of the fusion. Fusible fluxes (common salt, fluorspar), added in sufficient quantity, are of advantage, by dissolving oxide and dirt rather than preventing oxidation. A preliminary wash with dilute caustic soda, followed by table concentration and drying, would probably give a good yield of clean metal on a commercial scale. Most of the trouble in re-melting could, however, be prevented if the machine shops would keep the borings free from contamination. Some of the many laboratory experiments described gave recoveries as follows:—

	Total metal recovery.
Melting briquetted chips	76
Melting with continuous puddling	71—78
Melting with sal ammoniac	69.5
Adding scrap to "heel" of molten metal	66
Melting with 25% of flux (NaCl 85, CaF ₂ 15%) ..	78—80
Melting after washing with 0.5% caustic soda ...	75—85

—W. R. S.

Aluminium alloy; Acieral, an.—Eng. and Min. J., 1917, 103, 736.

AN American electric furnace plant with a daily capacity of 10 tons of acieral has been in operation for some weeks. The alloy (see Fr. Pat. 473,412 of 1914; this J., 1915, 558) is silver-white, has sp. gr. 2.82, and m. pt. 750°C . Its tensile strength in castings is given as 30,000, in rods and sheets as 28,000—61,000, and heat-treated as 70,000 lb. per sq. in. It resists the action of all acids except hydrochloric acid. It is stated that the alloy may be cast, forged, annealed, drawn, rolled, tempered, electroplated, and soldered and that it is being supplied to the French Government for the manufacture of helmets.—W. R. S.

Molybdenite; Concentrating Canadian.—H. H. Claudet. Canadian Min. Inst., Mar., 1917, Eng. and Min. J., 1917, 103, 786—788.

ALTHOUGH containing a high percentage of pyrites and pyrrhotite, together with some mica, the present Canadian molybdenite ores are sufficiently free from bismuth, nickel, or tungsten minerals to be concentrated readily to a product containing 40—50% MoS_2 which can be smelted in the electric furnace for the direct production of ferromolybdenum. The production of molybdenite in Canada has been developed mainly by the film-flotation method in the Wood machine or its modifications, but oil-flotation by the Elmore vacuum process, as used in Norway, has been also employed to some extent. Water concentration, although formerly used, is not efficient owing to the nature of the ore. In the film-flotation method the ore is "dried" sufficiently to oxidise slightly the iron sulphides without affecting the molybdenite, then crushed to 20—30 mesh size and treated with water. The dry molybdenite floats on the surface while the gangue and oxidised sulphides become wet and sink. The tailings are treated on a Wilfley table to recover the larger fragments of molybdenite which have sunk in the water through being rounded; the concentrates are also re-treated. In the Elmore vacuum process preferential flotation of the molybdenite in wet-crushed, unsized, 10—20 mesh ore is obtained by mixing the thickened pulp with a

very small quantity of coal oil or other light oil and subjecting the mixture to reduced pressure. Under suitable conditions high-grade concentrates and low-grade tailings are the only products obtained by this method which, although possessing marked advantages over the film-flotation process, requires a more bulky plant than the latter. In the film-flotation apparatus of the Canadian Government ore-testing plant at Ottawa, particulars of which are given, 2397.4 tons of Canadian ore containing 43.58 tons of molybdenum sulphide, MoS_2 , was treated, during 1916 and January, 1917, with a percentage recovery of 79.09% in the form of concentrates containing 79.95% MoS_2 . The amounts of concentrates and pure molybdenite produced in Australia, Norway, and Canada during 1916 were about 1590, 538, and 81 tons respectively. The Canadian production of pure molybdenite in 1915 (the first year of any commercial output) was 12.75 tons, and is now approaching 300 tons per annum.—W. E. F. P.

Flotation [of ores]: Percentage of oil in —.
H. A. Megraw. Eng. and Min. J., 1917, 103.
779—781.

IN December 1916 the United States Supreme Court decided in the case of Minerals Separation Ltd. *versus* J. M. Hyde that froth-flotation processes in which the proportion of oil employed is less than 1% of the dry weight of the ore (as in the Minerals Separation Ltd. patents) differ radically in theory and effect from those in which more than 1% of oil is used. Consequently, processes employing the smaller amount of oil are subject to the payment of patent royalties. From an investigation of the records of experimental and practical work at various plants, in which the proportion of oil used has been increased to above 1% since the above decision, it is concluded that although in most cases the extractions approximate to those previously obtained, in many the operating costs are higher than formerly. In general, the data on the use of the larger quantity of oil shows a constantly increasing percentage of extraction, a slowly but constantly improving grade of concentrates, and a very gradual reduction of the total costs. At the present time the amount of ore being treated by froth-flotation processes using more than 1% of oil is about 5000 tons per day.—W. E. F. P.

Heat of formation of ferrous sulphide. Parravano and De Cesaris. See VII.

PATENTS.

Magnetic separators. F. Krupp Akt.-Ges. Grusonwerk, Magdeburg-Buckau, Germany. Eng. Pat. 100,062, Jan. 11, 1916. (Appl. No. 481 of 1916.) Under Int. Conv., Feb. 6, 1915.

THE magnetic fields of the separator are divided into zones of increasing or decreasing magnetic strength, in which all the poles lie on one side of the feeding device. The poles are adjustable and are arranged one above the other, the material during its descent being separated into strongly and feebly magnetic fractions. The distance between two poles can be regulated in the direction in which the material moves, and vertically thereto. Wholly or partially magnetisable rings are mounted co-axially between the magnet system and the material to be treated; the magnet poles are so constructed that the lines of force enter the rings at the sides and the vertical pull on the rings is thus eliminated.—W. R. S.

Magnetic separators. A. Davies, London, and E. Allen and Co., Ltd., Sheffield. Eng. Pat. 105,354, Mar. 7, 1916. (Appl. No. 3376 of 1916.)

IN a separator of the type in which one or more magnetisable rings rotate relatively to a magnetic

field through which the material to be treated is passed, the rings are interrupted at one or more parts of their periphery by sectors of magnetisable material displaced radially relatively to the main magnetic rings, so as periodically to diversify the magnetic field and prevent bridging of the magnetic material between the poles and the attracting rings.—W. R. S.

Alloy containing magnesium; Production of an — serving for the deoxidation of cast iron or steel. Chem. Fabr. Griesheim-Elektron, Frankfort, Germany. Eng. Pat. 100,848, July 10, 1916. (Appl. No. 9714 of 1916.) Under Int. Conv. Apr. 28, 1915.

IN the process claimed in Eng. Pat. 24,007 of 1908 (this J., 1909, 480, 1143) the deoxidiser is prepared by adding magnesium or its alloys with aluminium or nickel to ferrosilicon (Si 50—80% while the latter is in a viscid or pasty condition).—W. R. S.

Zinc; Electrolytic deposition of — on metallic surfaces. P. Marino, London. Eng. Pat. 105,255, Mar. 31, 1916. (Appl. No. 4780 of 1916)

THE electrolyte consists of a concentrated aqueous solution of a zinc salt, to which 8 to 10% of glyceric sulphuric acid (prepared by adding sulphuric acid, sp. gr. 1.12, to one-sixth of its volume of glycerol), 8 to 10% of boric acid, and 5 to 10% of a halogen derivative of lactic acid (prepared by treating zinc chloride with a hot solution of an equimolecular proportion of lactic acid) have been added.—B. N.

Treating [electroplating] articles electrolytically. Apparatus and method of —. C. J. Lan and D. L. Honeyman, London. Eng. Pat. 105,582, Mar. 18, 1916. (Appl. No. 4035 of 1916)

THE articles are fed by electrical means into the vat at regular intervals on an endless conveyor and are maintained in close electrical contact with the cathode bars on the conveyor by magnetic action. When the articles reach the middle of the vat, they are transferred by a revolving drum to the second portion of the conveyor and thence from the vat. The drum is provided with magnetic means for holding the articles for sufficient length of time to turn them over in their passage over the drum.—B. N.

[Melting] furnaces and the like; Oil fired —. I. Hall, Birmingham. Eng. Pat. 105,431, May 5, 1916. (Appl. No. 6452 of 1916.)

IN an oil-fired melting furnace or the like, the combustion chamber is provided with a tangential inlet diverging towards the chamber and carrying adjustable cross-bars at its mouth to atomise the oil fuel. The burner nozzle is fixed concentrically with the inlet and is adjustable towards or away from it, so that the oil impinges on the cross-bars.—W. F. F.

Furnace; Smelting —. J. Kirby, Assignor to O. Kirby, Leechburg, Pa., J. B. Sommerville, Wheeling, W. Va., and S. M. Boyd, Pittsburgh, Pa. U.S. Pat. 1,222,636, Apr. 17, 1917. Date of appl., Dec. 15, 1916.

THE body portion of the furnace is provided with a pair of transverse bridge walls, between which a base plate is placed, thus forming a smelting chamber. Two flue chambers are arranged below and at opposite sides of the smelting chamber and each is provided with a set of longitudinal flues. A transverse partition wall is interposed between these flue chambers, the wall extending from the base plate of the smelting chamber to the bottom of the body portion, and forming a pair of transverse flues leading from the flue

chambers to a stack in the rear of the smelting chamber. The bridge walls, with the outer body portion, form two transverse flues leading to the melting chamber, and the bridge walls are provided with openings connecting these latter transverse flues with the longitudinal flues. A combustion chamber is arranged in front of the melting chamber, with means at the forward end of the partition wall for alternately opening and closing the other of the flue chambers to the combustion chamber, and a similar means provided for alternately closing and opening the stack to the open and closed flue chambers respectively.—B. N.

Furnace for the recovery of easily fusible metals (lead, tin, etc.) from scrap materials of all kinds; Continuous—C. Gauschemann, Frankfurt. Ger. Pat. 295,739, Sept. 10, 1915.

THE apparatus consists of a melting pan provided with a conduit for running off molten material, and built into a shaft, so that the products of combustion from a fire at the bottom of the shaft pass first under the pan and then over it. The material to be smelted is fed into the pan from a door above and the residues can be removed through a door in the side of the shaft just above the pan. This can be done continuously.—H. J. H.

Furnace; Electrically heated shaft—for recovering metals from low-grade ores and slags. Westdeutsche Thomasphosphat-Werke G.m.b.H., Berlin. Ger. Pat. 296,195, Aug. 6, 1915.

THE furnace contains a hearth in which the melting occurs, communicating with shafts at opposite sides through which the ore charge is applied. The electrodes hang vertically and bear of the charge on the hearth itself; air-gate doors for observation of and additions to the charge are provided. Heating is due to electric arcs set up between the electrodes, and with the addition of suitable reducing agents, slags and poor ores which cannot normally be profitably melted are completely freed from metal, e.g., high-grade ferromanganese can be recovered from slags containing 10–20% of manganese.—H. J. H.

Heating furnaces. C. Kugel, Brunswick. Ger. Pat. 296,102, Mar. 12, 1914.

THE temperature distribution in muffles for heating metal sheets and wires is often unsatisfactory, the temperature being excessive at the bottom. This is avoided by applying the heat to the side. The heating gases pass up vertically on both sides to meet over the middle of the roof of the muffle. Passing along horizontally to the end they are led downwards and into a horizontal flue running under the floor of the muffle and thence to the chimney.—H. J. H.

Alloy bearing. H. K. Sandell, Assignor to H. S. Mills, Chicago, Ill. U.S. Pat. 1,223,001, Apr. 17, 1917. Date of appl., June 19, 1916.

BEARING is formed from an alloy of 50% copper, 5% antimony, and 12.5% each of nickel and lead.—B. N.

Metal bodies; Process of producing—C. L. Gebauer, Cleveland, Ohio. U.S. Pat. 1,223,322, Apr. 17, 1917. Date of appl., Apr. 12, 1916.

METAL articles are moulded under great pressure from a mixture of finely disintegrated metallic constituents of varying melting points, and the mixture is subsequently treated at a welding temperature between the melting points of the constituents.—B. N.

Cowper stoves; Increasing the efficiency of—of blast furnaces. Wärme-Verwertungs-Ges. m.b.H., Siemensstadt. Ger. Pat. 295,831, Oct. 29, 1915.

WHERE recuperators are placed after the Cowper stove so as to heat up gas or air for use in furnaces by means of the waste heat from the blast-furnace gases, the resistance of the regenerative apparatus is always small and no considerable back pressure is thrown upon the Cowper stove. By increasing the resistance of the heat-exchange apparatus the back pressure is raised until equal to the strongest chimney draught. Thereby the possibility of the introduction of cold air by suction is excluded and the size of the apparatus can be diminished.—H. J. H.

Metals of different melting points; Separation of—H. Bendheim, Bensheim. Ger. Pat. 296,127, Apr. 25, 1915.

THE material from which the fusible metal is to be removed by melting is charged upon the perforated false bottom of a tray, supported on rails in a furnace chamber. The tray is heated by direct fire from below and is mechanically shaken backwards and forwards on the rails, which are so shaped as to impart to it a vertical motion also. The draining off of the fused metal is thereby facilitated.—H. J. H.

Furnaces [for heating metal billets]. A. Smallwood, London. Eng. Pat. 105,818, May 25, 1916. (Appl. No. 7445 of 1916.)

Hydrometallurgy [of ores]. E. R. Holden, Los Angeles, Cal. Reissue No. 14,298, May 8, 1917. of U.S. Pat. 1,175,867, Mar. 11, 1916. Date of appl., June 10, 1916.

SEE this J., 1916, 546.

Electric [smelting] furnace; Multiple-hearth—A. Helfenstein, Vienna, Assignor to Union Carbide Co. U.S. Pat. 1,223,278, Apr. 17, 1917. Date of appl., June 5, 1914.

SEE Fr. Pat. 473,416 of 1914; this J., 1915, 498.

Smelting-furnace. E. Ruck, Swansea. U.S. Pat. 1,223,738, Apr. 24, 1917. Date of appl., May 6, 1916.

SEE Eng. Pat. 8265 of 1915; this J., 1916, 1066.

Aluminium [foil]; Method for producing bands of—E. R. Lauber and R. V. Neher, Emmishofen, Switzerland. U.S. Pat. 1,225,044, May 8, 1917. Date of appl., Feb. 12, 1915.

SEE Eng. Pat. 20,455 of 1911, and Addition, dated Dec. 27, 1911, to Fr. Pat. 431,400 of 1911; this J., 1912, 192, 647.

[Electrical] commutator brush. Metal composition. U.S. Pats. 1,222,999 and 1,223,092. See XI.

XI.—ELECTRO-CHEMISTRY.

Electrolytes; Concentration of—in the vicinity of electrodes. S. Procopiu, Comptes rend., 1917, 164, 725–727.

IT is generally admitted that round an electrode there is a double (Helmholtz-Lippmann) layer of the electrolyte and that the remainder of the solution has a constant and definite concentration. Evidence is now submitted that there is another layer between the double layer and the remaining mass of the liquid, and the thickness of this layer is discussed.—W. P. S.

PATENTS.

Oxygen and hydrogen; Electrolytic production of —, G. F. Jaubert, Paris. Eng. Pat. 102,974, Dec. 28, 1916. Under Int. Conv., Dec. 29, 1915. (Appl. No. 18,553 of 1916.)

THE electrodes are covered by bells brought near to each other to diminish the resistance, and the active surface of each electrode projecting below the lower level of the bell is inversely proportional to the volume of gas liberated at each electrode, whilst the volume of each bell is directly proportional to the volume of gas liberated. The bells are provided with cocks, or outlet collectors for the gases, and with insulated sleeves for the cables connected to the electrodes.—B. N.

[Electrolytic] gas-generator. L. P. Sábille, Providence, R.I. U.S. Pat. 1,222,809, Apr. 17, 1917. Date of appl., June 16, 1916.

OXYGEN and hydrogen are generated electrolytically and collected in separate reservoirs. The pressure in each reservoir operates a valve which controls the flow of gas to the other reservoir. A device actuated by a float is provided for automatically shutting off the supply of gas to one reservoir when the pressure in the other exceeds that in the first by more than a predetermined amount.—W. F. F.

Electrolysing apparatus. R. J. J. Mueller, Assignor to Universal Oxygen Co., Sheboygan, Wis. U.S. Pat. 1,221,206, Apr. 3, 1917. Date of appl., Aug. 16, 1915.

A METAL tank is provided at the top with a flange projecting outwards, and with longitudinal partitions forming with the sides of the tank the electrodes of one polarity. An arched metal cover for the tank is provided with a corresponding flange, and the outer margin of a metal diaphragm support is fitted between the two flanges, but separated from them by insulating packing gaskets drawn tightly together by insulated bolts. The diaphragm support, thus separating the gas spaces above and below it, is formed integrally with depending gas conduits, through which pass metal plate electrodes, depending from the cover, alternating with the sides and partitions of the tank. Tubular diaphragms, surrounding the electrodes depending from the cover, are clamped in grooves in the lower ends of the gas conduits by rods and co-operating yokes; the diaphragms consist of material pervious to liquid, but when wetted are impervious to gas.—B. N.

Electric arcs; Process and apparatus for effecting chemical reactions by means of —, A. V. Lipinski, Zürich, Switzerland. Eng. Pat. 105,135, Apr. 28, 1916. (Appl. No. 6121 of 1916.)

ELECTRIC arcs are produced within a casing between practically equidistant electrodes, which are arranged in one or several parallel planes, and are connected to the various phases of a polyphase current, the arcs being spread magnetically into a disc-like or conical form; the electrodes may be annular and concentric or in the form of parallel bars. The gases are preheated within the outer casing, and are then forced through several openings against one or both sides of the flame. Cold reaction gases, or chilling substances in the form of powder, are blown through openings against one or both sides of the flame, so as to form a chilling zone on the outside of the reaction zone away from the flame, the chilling gases partly carrying the reaction gases forward, and partly exerting a suction effect upon them, whilst there is also a sharp fall in temperature between the two zones.—B. N.

Chemical gas-reactions by the aid of a diffuse electric discharge; Process for carrying out —, H. Andriessens, Munich. Ger. Pat. 296,395, Sept. 21, 1913.

THE reacting gases are led into an alternating current are struck between two parallel electrodes. Midway between the electrodes, with its axis at right angles to the plane of the electrodes is a magnetic field produced by an alternating current synchronous with that of the arc current.—B. V. S.

Galvanic cell. M. L. Kaplan, Brooklyn, N.Y., Assignor to Beacon Miniature Electric Co., Inc., New York. U.S. Pats. (A) 1,221,061 and (B) 1,221,062, Apr. 3, 1917. Dates of appl., (A) June 1 and (B) Nov. 20, 1914.

(A) HYDRATED manganese peroxide for use in Leclanché cells is produced by oxidising a mixture of two equivalents of manganous hydroxide and one equivalent of a manganous salt, with a hot solution containing two equivalents of potassium permanganate. (B) A depolarising agent for dry batteries of the Leclanché type is composed of a mixture of 10 parts of finely-divided graphite and 15 parts of an ignited, anhydrous, artificial higher oxide of manganese. The latter is free from water-soluble substances capable of causing local action, and has less combined oxygen than is shown by the formula, MnO_2 .—B. N.

Battery-depolarisers; Method of making —, M. E. Holmes, Lakewood, Assignor to National Carbon Co., Cleveland, Ohio. U.S. Pat. 1,221,991, Apr. 10, 1917. Date of appl., Aug. 25, 1913.

MANGANESE peroxide is deposited on powdered graphite from a solution of potassium permanganate and a manganese salt; steam is admitted before and during the precipitation, and the product is dehydrated by calcination.—J. H. L.

[Electrical] commutator-brush. Metal composition. H. K. Sandell, Assignor to H. S. Mills, Chicago, Ill. U.S. Pats. (A) 1,222,999 and (B) 1,223,002, Apr. 17, 1917. Dates of appl., (A) Mar. 20, (B) Sept. 12, 1916.

(A) A COMMUTATOR brush is cast from an alloy of about 50% copper, about 33% antimony, and about 17% of nickel and lead, with more than 5% of nickel. (B) A cast metal contact point, for making and breaking electrical circuits, is formed from a composition comprising substantially pure nickel containing upwards of 3% of uncombined graphitic carbon.—B. N.

Electrode [for electric furnaces] and coating therefor. J. C. King, Montreal, Canada. U.S. Pat. 1,223,986, Apr. 24, 1917. Date of appl., July 31, 1916.

THE coating comprises a mixture of 25 to 75% of graphite, and 75 to 25% of fireclay by weight, the mixture having approximately the same expansion and contraction as the material of the electrode.—B. N.

Electrolysis; Process for treating organic compounds by —, A. Piguet, Assignor to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,225,052, May 8, 1917. Date of appl., Dec. 31, 1915.

SEE Eng. Pat. 15,750 of 1915; this J., 1916, 384.

Process for purifying and improving cellulose preparations. Ger. Pat. 296,053. See V.

XII.—FATS; OILS; WAXES.

Fish-liver oils; Natural occurrence of high percentages of hydrocarbons in certain —, A. C. Chapman. Analyst, 1917, 42, 161—168.

THE presence of high proportions of hydrocarbons in shark-liver oils (this J., 1917, 392) involves a revision of the accepted constants for those oils. For example, the sp. gr. of Arctic and Japa-

shark oils at 15°/15° C. is given in text books as ranging from 0.9105 to 0.9285, whilst that of shark liver oils composed largely of the hydrocarbon ranged from 0.86 to 0.88, and it is probable that genuine oils may show intermediate values. Iodine values recorded for shark oils range from 98.9 to 162, whereas the hydrocarbon-containing oils show iodine values of about 360. Ordinary shark-liver oil, again, yields 20 to 25% of a bromine compound insoluble in ether, as compared with upwards of 76% obtainable from hydrocarbon-containing oils. In view of these facts shark-oil will in future have to be bought and sold on the results of analysis. Shark oil containing spinacene may be distinguished from fish-liver oils adulterated with added hydrocarbons by the high iodine value of the unsaponifiable matter and the high yield of bromides insoluble in ether. Since spinacene does not give the ordinary colour reactions of liver oils, shark-liver oil which contains it gives these colour reactions much more faintly than ordinary liver oils. Spinacene gave an efflux velocity of 78 sec. for 50 c.c. in Redwood's viscometer at 21° C., as compared with an average of 370 sec. for rape oil. As this hydrocarbon oxidises very readily, the use of oil containing it might be dangerous for such purposes as the oiling of wool (see Fairley and Burrell, this J., 1917, 113).—C. A. M.

Whale oil; Chemical composition of hardened —. B. Svendsen. Tidskrift Kem. Farm. og Terapi. 1916, [20], 285—292. Z. angew. Chem., 1917, 30, Ref., 95.

A SAMPLE of hardened whale oil had acid value 1.5, saponification value 195.7, iodine value 59.8, refractometer reading at 40° C., 50; it yielded no insoluble bromide. The fatty acids consisted of 10.8% of myristic acid, 17.9% of palmitic acid, 10.6% of Bull's C_{16} -acid (this J., 1906, 1158), 10.8% of stearic acid, 27.7% of oleic acid, 3.4% of arachidic acid, 8% of a solid acid, $C_{22}H_{40}O_2$, 2.5% of behenic acid, and 8.8% of a solid acid, $C_{22}H_{40}O_2$.

Eruic, brassidic, and isoerucic acids; Isomerism of —. V. L. Mascarelli. Gazz. Chim. Ital., 1917, 47, I., 160—167. (See this J., 1916, 262.)

RESULTS obtained by the cryoscopic and eutectic methods confirm the conclusions previously drawn with regard to the relationship of these acids. Between erucic and brassidic acids there is a relationship of true isomerism comparable with that existing between oleic and elaidic acids. The results also agree with those previously obtained which indicate that erucic acid has a *cis*- and isoerucic acid a *trans*- configuration. The relationship between brassidic and isoerucic acids does not appear to be one of true isomerism, but is more probably a case of polymorphism. —C. A. M.

PATENTS

Catalytically-useful substances [for hydrogenating oils]; Method of packing —. N. Sulzberger. New York. U.S. Pat. 1,223,123, Apr. 17, 1917. Date of appl., Sept. 5, 1916.

A PRECIPITATED catalyst obtained by treating a soluble nickel compound with sodium silicate, is preserved and rendered suitable for shipment by mixing it with hardened or hydrogenated cottonseed oil which is solid at ordinary temperatures. The solid mass may be cut into pieces containing known amounts of catalytic material. The catalytic product is suitable for hydrogenating further quantities of cottonseed oil.—W. F. F.

Detergents; Process of preparing —. A. Imhausen, Witten. Ger. Pat. 296,922, Dec. 11, 1915.

A DETERGENT is made from a mixture of soap,

petroleum spirit (benzine), and a compound which yields oxygen (sodium perborate), with the addition of alkali carbonate and an equivalent quantity of an acid, or of ammonium chloride, to protect the benzine vapours from oxidation and avoid the risk of explosion when the preparation is mixed with hot water.—C. A. M.

Catalytic device [for hydrogenating fats or oils]. J. Dewar, London, and A. Liebmann, Weybridge, Assignors to The Procter and Gamble Co., Cincinnati, Ohio. U.S. Pat. 1,222,608, Apr. 17, 1917. Date of appl., June 16, 1915.

SEE Eng. Pat. 15,668 of 1914; this J., 1915, 1102.

Catalysing agent for the reduction of fats and unsaturated fatty acids; Process of making a —. C. Paal, Erlangen, Germany, Assignor to The Hydrogenation Co., Cincinnati, Ohio. U.S. Pat. 1,222,660, Apr. 17, 1917. Date of appl., Mar. 18, 1911.

SEE Fr. Pat. 425,729 of 1910; this J., 1911, 1022.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Oil varnishes; Determination of volatile "thinners" in —. A. de Waele and F. Smith. Analyst, 1917, 42, 170—173.

VOLATILE solvents in oil varnishes may be rapidly and accurately determined by the following method:—From 3 to 4 grms. of the varnish is boiled with 60 to 70 c.c. of water in a carbon-dioxide flask over a free flame until no odour of the solvent is perceptible in the escaping steam (about 5 min.). To facilitate the removal of the solvent it is advisable to have a piece of weighed broken glass in the flask, which is kept in constant rotary motion during the boiling. After removal of the bulk of the water by decantation, a few c.c. of strong alcohol or methylated spirit is added, and the flask is immersed up to the neck in boiling water. This treatment is repeated with acetone until the residue appears quite clear, which indicates the removal of all water. The acetone vapour is then expelled by blowing, and the flask is cooled and weighed. The results thus obtained are usually about 1.5% lower than those given by McIlhenny's method (this J., 1895, 78), but it is pointed out that in the latter method an average allowance of 2 c.c. per 100 grms. of varnish is made irrespective of the nature of the distillate, and that it is probable that the allowance for the solubility of petroleum spirit in water should not be so high as this.—C. A. M.

Resin in rosin size; Determination of —. E. Heuser. Papier-Zeit., 1916, 41, 1503—1504. Z. angew. Chem., 1917, 30, Ref., 40.

A VOLUMETRIC method may be used instead of the more tedious gravimetric method:—25 c.c. of the size solution is treated in a separating funnel with dilute sulphuric acid and extracted with ether. The ethereal solution is washed with water until neutral, evaporated slightly, and made up with alcohol to 100 c.c. An aliquot portion of this solution is titrated with $N/10$ sodium hydroxide; the values calculated from the result coincide within 0.5% with those obtained gravimetrically. With sizes made from rosin of unknown origin, an average acid value of about 12 should be used in the calculation.—J. F. B.

PATENTS.

Paint or enamel material; Process of making —. L. Ornstein, Brooklyn, N.Y. U.S. Pat. 1,222,980, Apr. 17, 1917. Date of appl., May 1, 1916.

A MIXTURE of a phenol or cresol solution an

alkali, formaldehyde, and hydrochloric acid is allowed to settle in order to produce an oil-like precipitate. A second oil-like precipitate is produced by heating a mixture of a phenol solution, an alkali, and formaldehyde to the boiling point and adding a further quantity of formaldehyde. These two precipitates are then combined, with or without the addition of an acid salt.—A. B. S.

Titanic oxide pigment; Composite — and method of producing the same. L. E. Barton, Niagara Falls, N.Y., Assignor to The Titanium Alloy Manufacturing Co., New York. Reissue No. 14,289, Apr. 24, 1917, of U.S. Pat. 1,155,462, Oct. 5, 1915. Date of appl. Aug. 3, 1916.

SEE this J., 1915, 1104. The product, which may contain a small proportion of iron oxide, is a soft fine powder, of white colour faintly tinged with cream, and sp. gr. 2.95–3.10.

Titanic oxide pigments; Manufacture of composite —. H. Wade, London. From The Titanium Alloy Manufacturing Co., New York. Eng. Pat. 105,616, May 10, 1916. (Appl. No. 6701 of 1916.)

Process of preparing monoazo dyestuffs suitable for the manufacture of pigments. Ger. Pat. 296,931. See IV.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Plantation rubber; Investigations of the quality of — conducted under the Ceylon rubber research scheme. Bull. Imp. Inst., 1916, 14, 495–566.

THE investigations deal with the effect upon the mechanical properties of the vulcanised rubber of (1) different methods of coagulation; (2) the addition of substances to the latex to retard coagulation; (3) the form of the rubber; (4) the method of drying; (5) "over-working" freshly coagulated rubber in the washing machine; (6) various methods of smoking; (7) drying sheet rubber under tension; (8) rolling up wet and dry sheet rubber, with and without tension; (9) conversion of wet and dry crêpe into block; (10) separating the rubber from the latex in successive portions. The latex was obtained from two sets of trees, 7 and 16–20 years old respectively, on the Gikiyanakande estate Kalutara. Full details of the methods of preparing and of testing samples are given; control specimens were prepared in each section of the work. Under (1), spontaneous coagulation, and coagulation by acid and by heat were studied; under (2) the effect of ammonia, sodium sulphite, and formaldehyde; under (3) pressed and machine sheet, thin and thick crêpe and block; under (4) drying at different temperatures in the air, and in a vacuum dryer; under (6) were included the Wickham and Byrne processes. From the results obtained the following conclusions were drawn:—Spontaneous coagulation usually yields good, quick-curing rubber, but the method is scarcely

suitable for practical use. Vulcanised tree scrap has a low tensile strength. Acetic acid is a quite satisfactory coagulant, and is less likely to affect the rubber adversely than *e.g.*, sulphuric acid. Unsmoked sheet vulcanises fairly rapidly (rubber 90, sulphur 10%, 70 minutes at 50 lb. pressure (117.6 C.) in a mould) and gives good tensile results (2300–2400 lb. per sq. in.). Crêpe vulcanises much more slowly (105–130 minutes) than the corresponding sheet, and has very often inferior mechanical properties. Over-working of freshly coagulated rubber, in preparing crêpe, has little effect on mechanical properties of the vulcanised product or upon rate of cure (compared with lightly-worked crêpe). Thick crêpe built up from thin differs little from the latter in cure or strength, but when made direct from the coagulum cures quicker than the corresponding thin crêpe. Different methods of drying have very little effect. Smoking of sheet rubber lengthens the time of cure and sometimes affects mechanical properties adversely. Addition of alkaline cresote before coagulation does not affect the properties of dry sheet rubber. The Wickham and Byrne processes do not give superior mechanical properties in the vulcanised product. Pressing dry rubber into block, or rolling with or without tension has very little effect. Products obtained by fractional coagulation do not differ appreciably. Rubber allowed to remain wet after coagulation of creosoted latex, cures quickly and has good mechanical properties. Such rubber loses some protein on washing. Rate of cure appears to be related to the moist condition of the rubber and sometimes varies inversely with the amount of protein present, but a sample obtained by evaporation of latex *in vacuo*—containing therefore much protein—also cured very quickly. It would appear that a quick-curing rubber with good mechanical properties could be obtained by pressing wet creosoted sheet into blocks of suitable size. Bulking the product obtained over long periods seems at present to be the only method of ensuring approximate uniformity in rate of cure.—E. W. L.

Rubber; Sugar as coagulant for —. O. de Vries. Central Rubber Station, Buitenzorg. India-Rubber J., 1917, 53, 653.

AS a result of a number of comparative experiments on the coagulation of latex by acetic acid and by sugar, it was found that the differences between the rubbers produced were very slight. Tensile strength, "slope," and viscosity were nearly always the same, while in the rate of cure a small difference was generally observed, sometimes favouring acetic acid and sometimes sugar. In three series of experiments, the uniformity from day to day with sugar-coagulation equalled that with the acetic acid process. Preliminary observations indicate that sugar-coagulated rubber possesses good keeping qualities.

Raw rubber; Tackiness in —. K. Gorter. Gummi-Zeit., 1916, 30, 351. Chem.-Zeit., 1917, 41, Rep., 36.

SAMPLES of raw rubber contained in sealed tubes were unaffected by exposure to light when the tubes were filled with hydrogen or carbon dioxide, but became tacky when oxygen was present. Oxidation was slow during the first 6 days, then increased in speed, reaching a maximum in 30 days. Enzyme action is excluded, since samples sterilised by heat behaved in the same way. Aldehydes were present in the tacky rubber.—E. W. L.

PATENT.

Cloth for filler-presses. U.S. Pat. 1,222,100. See I.

XV.—LEATHER; BONE; HORN; GLUE.

Green walnut shells; Tannin content of —. J. Paessler. *Ledertechn. Runds.*, 1916, 8, 189. *Z. angew. Chem.*, 1917, 30, Ref., 48.

GREEN walnut shells contain 22.2% of a tannin which, though sensitive, is apparently usable. In addition the relation between this and the non-tans is satisfactory. The collection of these walnut shells for leather manufacture is recommended.—H. J. H.

Humic acid and tannins. W. Moeller. *Collegium*, 1916, 330–333, 356–359. *Z. angew. Chem.*, 1916, 29, Ref., 520.

EXTRACTS made from decomposing oakwood give the Procter-Hirst reaction for sulphite-cellulose with an intensity varying with the degree of decomposition, and evidently contain compounds similar to those present in sulphite-cellulose. Extracts of other decomposed vegetable materials also give the reaction, which apparently depends on the presence of the humic acid always formed by the decomposition of wood, etc. Hide tanned with humic acid showed the characteristic defects of a sulphite-cellulose tannage.—F. C. T.

Humic acid and tannic acid. W. Moeller. *Collegium*, 1916, 385–393. *Z. angew. Chem.*, 1917, 30, Ref., 48. (See preceding abstract.)

THE whole of the tannin can be precipitated from solutions by humic acid with the addition of hydrochloric acid. As the quantity of humic acid necessary varies with the kind of tannin, the author holds that the "humic acid value" should be useful in analytical work. With tannin solutions containing sulphite-cellulose, a separation is possible by the use of humic acid.—H. J. H.

Tanning substances; Fischer's synthesis of depsides and —. J. A. Wilkinson. *South Afr. J. Sci.*, 13, No. 4. *Chem. News*, 1917, 115, 208–209, 217–218.

THIS paper summarises Fischer's work on the synthesis of depsides and the constitution of gallo-tannic acid. (See this J., 1913, 500; 1912, 503 and 1043.)—F. C. T.

PATENTS.

Leather; [Tanning] process for manufacturing —. F. W. Weber. *Perth Amboy, N.J.*, Assignor to the Roessler and Hasslach Chemical Co., New York. U.S. Pat. 1,221,929. Apr. 10, 1917. Date of appl., Sept. 11, 1915.

THE hides are prepared in any suitable manner and then soaked in a solution of a zinc salt and a tanning liquor, the latter consisting of a solution of chromium sulphate, having as a maximum two mols. of base to three of acid or as a minimum four of base to five of acid. The hides are then treated with a solution of a "diphosphate," and sufficient peroxide to neutralise the diphosphate, rinsed, and treated with fat, to act on the oxygen retained in the pores.—B. N.

Tanning hides and skins; Process for —. L. Schupp. *Neckargemünd.* Ger. Pat. 296,071. June 10, 1914.

THE hides and tan liquor are contained in a revolving drum in which a vacuum is maintained. The bulk of liquor diminishes by evaporation, but the reduced pressure makes it possible to draw fresh liquor into the drum through a channel in the axle without interruption of the process. The evaporation has a cooling effect and prevents the heating up of the charge. The tanning process is accelerated and has a beneficial effect on the leather produced.—H. J. H.

Stabilising of bile and other tryptic enzymes [e.g., artificial bates]; Process of —. O. Riehensahn, Wohlauf, Germany. Ger. Pat. 296,361. May 26, 1916.

BILE or other like enzyme preparation is treated with aluminium silicate, when it may be preserved for months free from smell.—F. W. A.

Electro-tanning; Method and apparatus for —. L. A. Groth. London. U.S. Pat. 1,222,861. Apr. 17, 1917. Date of appl., Oct. 5, 1914.

SEE Eng. Pat. 19,239 of 1912; this J., 1913, 952.

Dyeing of tanned cat's-skin in the hair, and of goods produced therefrom. Ger. Pat. 296,394. See VI.

XVI.—SOILS; FERTILISERS.

Soil; Biological changes in — during storage. F. E. Allison. *Soil Sci.*, 1917, 3, 37–62.

TO ascertain how long a fresh soil sample would be kept without alteration of its biological properties, four different soils (Penn shaly loam, Penn gravelly loam, Sassafras sandy loam, and Alloway clay) were investigated. The samples were taken in winter, when the ground was lightly frozen, and it was found that the bacterial numbers underwent a marked initial decline in the first two hours, and then began to rise. After the first day there was another decrease, followed by a steady increase between the fourth and seventeenth days. Hence, in winter, change of temperature is the factor determining the bacterial numbers in a soil on removal from the field to the laboratory. Ammonification of the nitrogen in peptone and in dried blood tended to vary directly with the numbers of bacteria whether in solution culture or in the soil itself. The effect of storage on azoifying and nitrifying organisms was very small. Similar experiments made on air-dried soil samples showed, generally, a marked decrease in bacterial numbers and activities during the drying. The decrease was particularly great for the clay and sandy loam soils, but was absent entirely from the shaly loam. The decrease in the ammonification of peptone was great for all soils, but with dried blood ammonification was as rapid in air-dried as in moist samples. The experiments were repeated on samples of shaly loam and sandy loam taken in mid-summer, and similar results were obtained, except that the biological changes were much less abrupt, the decrease in bacterial numbers and of ammonifying power continuing slowly for at least two months. During the winter months, plates should be poured for the bacterial counts and ammonification tests should be started immediately the soil is brought into the warm laboratory. In summer, it is advisable to start the counts without much delay, but the ammonification experiments need not be begun for about 10 days.—E. G. T.

Soil bacteria; Effect of some acids and alkalis on — in the soil solution. O. M. Gruzit. *Soil Sci.*, 1917, 3, 289–295.

SOIL solutions were extracted from a sandy and a rich sandy loam soil and after treatment to render them acid, alkaline, or neutral, were placed in pure sterile sand, bacterial counts being made at intervals on sodium asparaginate agar. With N/1200 hydrochloric or sulphuric acid about 99% of the bacteria were destroyed; with N 2164 acid the number remained constant; and with N/2840 acid the growth was inhibited to the extent of 13%, as compared with the growth in presence of N/112 alkali, almost exactly corresponding to the toxic action of this strength of acid to Indian corn (maize) seedlings. Alkali solutions became toxic at a concentration of N/1000; on standing they gradually became neutral and

then acid. Neutral media supported bacterial life only feebly and for a short time, and as they became acid the bacterial numbers diminished rapidly.—E. H. T.

Soil: Organic matter of the ——. III. Production of humus from manures. R. A. Gortner. *Soil Sci.*, 1917, 3, 1—8. (See this J., 1917, 226, 227.)

POWDERED silk waste, powdered wool, flour, and alfalfa (lucerne) meal, were added to moist subsoil from the farm of the Minnesota Agric. Exp. Station, the mixtures moistened with infusion of soil bacteria, and left for one year in bottles in a greenhouse, the moisture content being kept constant. Determinations of the organic carbon, nitrogen, and humus showed that the incubation had resulted in a loss of carbon, varying from 18.4 to 55%, a loss of nitrogen (50–26.5%) which was not proportional to the loss of carbon, and a loss of ammonia-soluble humus, the amount of which appeared to be directly proportional to the loss of nitrogen. When the humus extractions were made without previous leaching with 1% hydrochloric acid, there was no appreciable change in three cases, and in the fourth there was a loss of 60%. Hence the belief in the specific humification of organic material added to a soil appears to be without foundation. (See also Fraps and Hammer, *Texas Agric. Exp. Stat., Bull. No. 129*, 1910.) —E. H. T.

Soil: Organic matter of the ——. IV. Some data on humus-phosphoric acid. R. A. Gortner and W. M. Shaw. *Soil Sci.*, 1917, 3, 99—111. (See preceding abstract.)

DETERMINATIONS of the phosphoric acid contents of the ash derived from the humus which had been extracted with 1% ammonia solution (as NH_4OH) without preliminary leaching, and of that extracted by leaching with 1% hydrochloric acid, showed that in three of the eight soil types more phosphorus was dissolved by the former process than by the latter, and only in one case did the acid extract more phosphoric acid than the alkali. No relation could be traced between the amounts of phosphoric acid extracted directly by ammonia and that extracted by the same solvent after leaching with hydrochloric acid, nor between the humus-phosphoric acid contents and the known fertility of the soils. Although no analytical method of differentiating organic phosphoric acid and that adsorbed by soil colloids has been devised, yet it is probable that the phosphoric acid in humus is mostly of inorganic nature. The fact that the ash content of ammonia extracts of the same soil varied between 6.7 and 32.6% shows that much adsorbed mineral matter must have been present. Similarly, determinations of humus potash are vitiated by the presence of adsorbed potassium compounds, and probably potash occurs in soils only in inorganic combination.—E. H. T.

Lime-requirement methods; Relation between indications of several — and the soil's content of bases. C. J. Schollenberger. *Soil Sci.*, 1917, 3, 279—288.

THE utility of many methods of determining the lime-requirement of soils is restricted because the indications afforded by them do not agree sufficiently accurately with the requirements of field-practice. Nevertheless the data supplied by such determinations, when properly interpreted, throw light upon the changes taking place in the basic materials of a soil. Experimenting upon a Miami clay loam and upon a Clyde clay soil, both acid-extracted and washed, the vacuum method (heating the soil with finely-divided calcium carbonate under diminished pressure and determining the liberated carbon dioxide) was found to be the most nearly quantitative, as well as the most

generally applicable. The results obtained by the Hutchinson-MacLennan method (this J., 1914, 932) gave consistent results for the two soils, and although they ran parallel to those from the vacuum method, they were consistently lower; the tests with unextracted soils resulted similarly. Outdoor pot experiments on a variety of soils containing growing soya beans, wheat, and clover, showed that the addition of quantities of precipitated calcium carbonate, indicated as necessary by the vacuum method, rarely led to results which were not satisfactory. A few experimental data indicated the existence of a relation between the percentage of the total lime-requirement satisfied and the reaction to litmus, carbonates being absent.—E. H. T.

Nitrous nitrogen in irrigated soils. J. E. Greaves, R. Stewart, and C. T. Hirst. *Soil Sci.*, 1917, 3, 119—151.

THE results of over eight hundred determinations of nitrous nitrogen in a calcareous soil during four seasons, showed that the amount was very small, but evenly distributed throughout the soil. The total quantity varied from a mere trace to 17 lb. per acre, and variations in the amount of irrigation water and in the application of manure had no appreciable influence. There was no observable relationship between the nitrous and nitric nitrogen contents, the ratio varying from 1:3.03 to 1:80. A slight seasonal variation was discovered; with alfalfa (lucerne) and oat crops the nitrous nitrogen was highest in the spring and fell towards autumn, with potatoes and maize it was lowest in the spring and highest in the autumn. The maximum amount in fallow soil was found in mid-summer, and in alfalfa soil during the spring, whilst soil under oats contained the least during mid-summer. —E. H. T.

Nitrogenous fertilisers; Ammonifiability versus nitrifiability as a test for the relative availability of —. C. B. Lipman and P. S. Burgess. *Soil Sci.*, 1917, 3, 63—75. (See also this J., 1917, 229.)

AMMONIFICATION and nitrification tests were performed on dried blood, high-grade tankage, steamed bone-meal, cottonseed meal, and fish guano, in presence of 22 different soils, mostly of the arid type. The ammonification experiments were carried out with 50 grms. of soil and 1 gm. of fertiliser contained in tumblers, the whole being incubated for 7 days at 28°–30° C., and the ammonia determined by the magnesia-distillation method. The nitrification data were obtained, after incubating 100 grms. of soil and 1 gm. of fertiliser for four weeks, by the phenoldisulphonic acid colorimetric method. The results obtained were very discordant, in fact the order of availability was often exactly reversed according to the method employed. Since nitric nitrogen is regarded as the most important form of the element for plant nutrition, the nitrification tests are recommended as the safest criterion of availability of nitrogenous fertilisers, at least for arid soils.—E. H. T.

Phosphorus; Effect of — on alfalfa (lucerne) and alfalfa bacteria. H. W. Truesdell. *Soil Sci.*, 1917, 3, 77—98.

THAT alfalfa and some other legumes respond readily to phosphorus treatment is a well-established fact, and the considerations that bacteria such as *Azotobacter chroococcum* contain a relatively higher percentage of the element than many of the higher plants, that phosphorus acts as a stimulant to various groups of bacteria, and that its application results in the increased development of the root-nodules of many leguminous plants, leave no doubt that its fertilising action on alfalfa is a consequence of bacterial action. The effect of the addition of the diphosphates of potassium, sodium,

and calcium to sterilised soils inoculated with a pure culture of the alfalfa organism, *B. radicola*, was greatly to increase the number of organisms, the increase varying with the nature and the solubility of the salt. Alfalfa seed was grown in the greenhouse in pots, and the soil treated with calcium phosphate (CaHPO_4) with and without the addition of urea, the conditions being aseptic throughout except for the addition of alfalfa bacteria at the time of planting. An early increase in the growth was observed, and this was ascribed to direct plant nutrition, to stimulation of the plant cells, and to the quickening of bacterial processes in the soil. After the seedling state was passed, the nodule formation, the dry weight of the roots, and the total nitrogen content were all increased; and when the plants were cut for the third time, it was discovered that the phosphorus treatment was responsible for a part of the nitrogen increase; hence the treatment had stimulated the bacterial activity and caused a greater fixation of nitrogen.—E. H. T.

Seeds; Some effects of salt-treated soils on absorption by—W. F. Gericke. Soil Sci., 1913, 3, 271—278.

LABORATORY experiments were undertaken to find out if the addition of certain toxic salts to a light sandy soil had any effect upon the absorption of water by seeds planted in it, the absorption being measured by weighing. Applications of copper sulphate at the rate of 125—500 parts of anhydrous salt per million of soil produced an increased absorption with bean and barley seeds, but the results obtained with maize were indefinite; with 150 parts per million the rate of absorption was retarded in all three cases. Similar experiments with sodium carbonate showed that the smaller applications favoured absorption, and with sodium chloride, small or large applications decreased the absorption of water by all the seeds used.—E. H. T.

PATENTS.

Calcium cyanamide; Process for granulating—G. W. Sinclair, Petersham, Surrey, and Nitrogen Products and Carbide Co., Ltd., London. Eng. Pat. 105,578, Mar. 16, 1916. (Appl. No. 3924 of 1916.)

CALCIUM cyanamide in powder form is treated with 10—20% of water, the heat of reaction being maintained above 60° C. but below 100° C. A second quantity of 12% of water is then added, the temperature being kept between 20° C. and 45° C., and the mass is compressed under rollers into granular form. A diluting material, such as fine calcium cyanamide dust from a previous operation, may be added between the two additions of water. To prevent, as far as possible, separation of dust, the drying of the material may be conducted in an atmosphere of aqueous vapour, such as that given off from the material itself.—J. H. J.

Manurial value of gas liquor; Process for increasing the—A. Schubert, Pasing, Germany. Eng. Pat. 105,729, Dec. 11, 1916. (Appl. No. 17,818 of 1916.)

XVII.—SUGARS; STARCHES; GUMS.

Trimethylglucose from cellulose. W. S. Denham and H. Woodhouse. Chem. Soc. Trans., 1917, 111, 244—249.

THE authors present arguments to show that it is not likely that the crystalline trimethylglucose obtained by them from cellulose (this J., 1914, 1084) is a derivative of γ -glucose (see this J., 1914, 770 and 1915, 627), and that it probably has a

butylene oxide structure. Condensation of the trimethylglucose with hydrogen cyanide, followed by hydrolysis, yields an acid which behaves on titration as if partly lactonised, but containing only two methoxy groups. Of the possible formulae the one which best represents this behaviour of the trimethylglucose is

Sugar liquor; Processes of refining—J. A. McCaskell, Salt Lake City, Utah. U.S. Pats. (A) 1,221,553 and (B) 1,221,554, Apr. 3, 1917. Date of appl., Aug. 17, 1915. Renewed Feb. 5, 1917.

(A). For the filtration and decolorisation of sugar-liquors or other liquids containing suspended matters, a filtering material of greater specific gravity than the suspended matter is mixed with the liquid, and the whole filtered so as to form a cake, which may afterwards be disintegrated in presence of a liquid and freed from lighter impurities by subsidence, or which may be re-vivified *in situ* and used repeatedly before being broken up. (B) Sugar liquors are mixed with bone charcoal and filtered, and the cake, washed free from sugar, is broken up, freed from lighter foreign matters, and used again for further quantities of liquors. The filtered liquors are decolorised by mixing with another charge of charcoal and filtering; the cake is washed *in situ*, revived, and used in the treatment of further quantities of filtered liquors.—J. H. L.

Starch; Process of obtaining—H. C. Holden, Pittsburgh, Pa., Assignor to Washburn Crosby Co., Minneapolis, Minn. U.S. Pat. 1,221,990, Apr. 10, 1917. Date of appl., July 3, 1916.

IMPURITIES such as gluten and fibrous materials are removed from starch liquor by entanglement in a voluminous froth produced by injection of air, and carried over into a separate receptacle.—J. H. L.

Starch; Apparatus for freeing lump— from adhering dust or powder. A. W. H. Lenders, Cedar Rapids, Iowa. U.S. Pat. 1,223,406, Apr. 24, 1917. Date of appl., June 6, 1914.

LUMP starch is fed into a hopper from which it falls through a short tube with perforated sides, across which currents of air are directed from a central pipe. A suction hood surrounds the perforated pipe for the purpose of carrying away the dust removed from the starch.—J. H. J.

Starch; Process of making—and products thereof. C. C. Moore, Washington, D.C., Assignor to F. C. Stevens, Attica, N.Y. U.S. Pat. 1,221,951, May 8, 1917. Date of appl., Dec. 16, 1911.

XVIII.—FERMENTATION INDUSTRIES.

Barley: Behaviour of the mineral substances of — during germination. W. Windisch and W. Dietrich. *Jahresb. Versuchs- und Lehranst. für Brau.* Woch. Brau., 1916, **33**, 353—354.

THE authors studied the distribution of lime, magnesia, and phosphoric and sulphuric acids in the barley corn during malting. The proportions of these constituents which can be extracted by water at 0° C. increase in the course of germination but diminish again during the kilning process. Lime, magnesia, and phosphoric acid pass into the growing rootlet in such quantities as to maintain there practically the same concentration as in the rest of the corn. Sulphur passes into the rootlet in relatively larger amounts, so that the sulphur-content of the endosperm falls below that of the growing parts, and this in spite of the fact that throughout germination only about 9% of the total sulphur of the corn is present as soluble sulphate. The authors conclude that the remainder of the sulphur is present as a constituent of proteins and that the mechanism of the transference of sulphur to the rootlet consists in transformation of protein sulphur into soluble sulphate in the endosperm, diffusion of the soluble sulphate into the embryo, and reconversion there into protein sulphur.—J. H. L.

Yeast: Observations on —. T. Bokorny. *Pflüger's Archiv*, 1916, **164**, 203—273. *Woch. Brau.*, 1916, **33**, 231—232. (See also this J., 1916, 612, 900.)

YEAST weakened by several hours' treatment with 0.1% formaldehyde solution, phenol, mercuric chloride solution, or chloroform water, was found to ferment sucrose or maltose solutions more rapidly than dextrose solutions of the same concentration. It is suggested that when sucrose or maltose is hydrolysed by yeast enzymes, the hexoses formed are in the nascent state more reactive than in their ordinary condition. Yeast decomposes amygdalin (although hydrocyanic acid is strongly toxic), but not salicin, arbutin, or coniferin. It assimilates nitrogen more readily from peptone than from asparagine, aspartic acid, leucine, tyrosine, glycine, urea, ammonia, or somatose (flesh albumose), the last-named being unassimilable. Storage of pressed yeast at -15° C. for 24 hours, was found to have no effect on its reproductive and fermentative powers, and drying at the ordinary temperature destroyed only the maltase amongst the yeast enzymes. Three weeks' storage of yeast in 50% sugar solution destroyed the zymase but not the invertase. The growth of yeast was found to be inhibited in presence of solutions containing 0.01% of hydrofluoric acid or copper sulphate, 0.1% of caffeine, formaldehyde, or hydrochloric acid, 0.5% of phosphoric acid, or 5% of ethyl alcohol.—J. H. L.

Cider yeasts. E. Kayser. *Comptes rend.*, 1917, **164**, 739—741.

OWING to the great demand for alcohol, attempts have been made to produce it from a mixture of beetroot and apple juice, but the product was found to contain large quantities of esters and volatile acids. It is shown that this is due to the presence of cider yeasts the activity of which preponderates over that of other yeasts, particularly in cases where sulphuric acid has been employed in obtaining the beetroot juice by diffusion. Ordinary yeasts will scarcely tolerate an acidity of 0.09% of sulphuric acid, whilst cider yeasts are still active in a solution containing 0.2% of sulphuric acid. In fermenting such mixtures, acidity should be kept as low as possible and the temperature maintained below 10° C., so as to minimise the formation of esters and volatile acids by the cider yeasts.—W. P. S.

Alcohol: Determination of —. A. Ponyo. *Communications, U.S. Master Brewers' Assoc.*, 1917. *Western Brewer*, 1917, **48**, 84—85.

IN the determination of alcohol in hopped beverages the results are liable to be slightly high (e.g., by 0.02—0.01%), owing to traces of hop constituents carried over during distillation which reduce slightly the specific gravity of the distillates. Theyenet (*Western Brewer*, 1917, **48**, 61) has stated that these hop constituents are acid in character and that the error mentioned may be entirely avoided if the liquid to be distilled is first rendered slightly alkaline. The author, however, failed to detect any indication of acidity in distillates from hopped liquids, and found that the error in question was not obviated by addition of calcium carbonate before distillation, as recommended, in the methods of the U.S. Association of Official Agricultural Chemists, for beverages of excessive acidity. The error is usually very small, but might be greater in cases where part of the hops is added only shortly before the conclusion of wort-boiling.—J. H. L.

Brewers' grains: Composition of —, and the dust from them. H. F. E. Hulton and J. L. Baker. *J. Inst. Brew.*, 1917, **23**, 254—255.

THE dust produced during the drying of mash-tun grains was analysed and found to be considerably richer in protein, and of greater feeding value, weight for weight, than the grains as a whole. The dust should therefore be as uniformly blended with the grains as possible, to raise their feeding value. It constitutes a dangerous source of wort infection, so should not be allowed to blow about in the vicinity of a brewery.—J. H. L.

Regular and irregular antiseptics. Richet and others. See XIXb.

PATENTS.

Musts, wines, brandies, alcohols, syrups, honey substitutes, and jellies: Process for preparing —. E. Disdier, Malaga, Spain. *Eng. Pat.* 105,282, June 9, 1916. (*Appl. No.* 8202 of 1916.)

THE residue obtained in pressing grapes, consisting of pulp and skins with about 50—60% of must, is freed from stalks, dried, and then freed from stones or seeds. The product, which may be kept indefinitely without spoiling, is used in conjunction with sugar solutions, for the preparation of musts, syrups, fermented beverages, etc.—J. H. L.

Beverage: Process for making a non-alcoholic —. A. L. Straus, Baltimore, Md. *U.S. Pat.* 1,223,121, Apr. 17, 1917. *Date of appl.*, Feb. 23, 1917.

FERMENTED malt liquor is boiled to remove alcohol, and hot water is added equal to that evaporated. During the boiling, salt, hops, gum arabic, and sugar are added, with more hops at the close. After boiling is completed, the temperature is rapidly reduced to 4° C. and 0.5—1 oz. of "liquid quassia" added per barrel of liquor, together with finings and a chill-proof preparation. The beverage is stored for 2—5 days, and during this period four tablets of potassium metasilphite are added to each barrel. After storage, the beverage is filtered and carbonated.—J. H. J.

Apparatus for dephlegmation. *U.S. Pat.* 1,222,801. See I.

XIXa.—FOODS.

Bread making with various flours. Balland. *Comptes rend.*, 1917, **164**, 712—714.

BAKING experiments showed that quite satisfactory bread can be made from wheat flour mixed with from 10 to 15% of its weight of barley, rye, maize,

rice, or tapioca flours, but the best results are obtained with a mixture of wheat and barley flours. Slightly roasted earthenut meal, after the excess of oil has been expressed, may be added to wheat flour to the extent of 10%, but the resulting loaf has a dark colour.—W. P. S.

Condensed milk. H. de Rothschild and C. Porcher. *Ann. Falsif.*, 1917, 10, 111—129.

EXAMINATION of samples of many brands of condensed milk which have appeared recently on the French market showed that the weight of the contents of the tins in some cases varied by as much as 50 grms.; differences were found in the composition of the milks, the chief variations being as follows:—Unsweetened whole milk, total solids, 23.6 to 32.7%. Sweetened whole milk, total (milk) solids, 32.7 to 43.1%, sugar, 25.4 to 43.42%. Sweetened skimmed milk, total (milk) solids, 25.1 to 32.6%, sugar, 32.9 to 49.8%. As regards the composition of the original milk, it was found that, in one case, the milk could only have contained 2.7% of fat, although the condensed milk was sold as being made from whole milk. It is suggested that all receptacles containing condensed milk should bear a statement as to the weight of their contents or, better, the volume of normal milk which the condensed milk will yield when suitably diluted; the degree of concentration and the quantity of added substances should also be indicated on the label. Antiseptics or preservatives should not be present.—W. P. S.

Eggs; Deterioration of—Lindet and Husson. *Ann. Falsif.*, 1917, 10, 106—111.

THE quantity of ammonia in eggs increases on keeping; in the case of fresh eggs, the white contains 0.006% and the yolk 0.016% of ammonia. After six weeks, the white contains 0.015 to 0.022% and the yolk 0.030%. Many different kinds of bacteria are found in eggs, together with some moulds; the latter have but a feeble peptonising action, the greater changes being effected by the bacteria. Hard-boiled eggs become "bad" much more rapidly when kept than do raw eggs under the same conditions.—W. P. S.

Corn [maize] as a source of protein and ash for growing animals. A. G. Hogan. *J. Biol. Chem.*, 1917, 29, 485—493.

CALCIUM is the principal mineral substance which is lacking in the ash of maize, but there appears to be no deficiency in phosphate constituents. The proteins of maize are deficient in tryptophane and, to a less extent, in lysine.—W. P. S.

Vitamines; Chemical nature of—III. *Structure of the curative modifications of the hydroxypyridines.* R. R. Williams. *J. Biol. Chem.*, 1917, 29, 495—520. (See this J., 1916, 912, 1081, 1130.)

THE two crystalline forms of α -hydroxypyridine are isomeric and can be converted into one another, the stability of each form being determined by temperature, solvent, etc. Only the form crystallising in needles is curative for polyneuritis; the corresponding crystal form of γ -hydroxypyridine and the anhydrous forms of methylpyridone, trigonelline, and betaine have similar curative properties, but the three last-named substances do not appear to have any protective action. It is concluded that the curative form of α -hydroxypyridine is a *pseudo*-betaine and that more or less conformity in structure or energy conditions to the type of a betaine is an essential characteristic of antineuritic vitamins. There is a theoretical possibility of the existence of such a structure in most of the simpler nitrogenous constituents of animal tissues, and especially in the nucleic bases. Nicotinic

acid may exist in a betaine form and the curative properties of Funk's vitamine may have been due in part to this isomeric form of nicotinic acid or to a polymeride or simple derivative of it.—W. P. S.

Flavouring extracts; Canadian standards of quality for—.

AN Order-in-Council, dated 31st March, 1917, specifies the new standards of quality which have been established for flavouring extracts, in substitution of those established by Order-in-Council of the 17th October, 1912. The new standards are as follows:—

1. A flavouring extract intended for the purpose of flavouring food, is a solution of correct strength, as hereinafter defined, of sapid and odorous principles derived from an aromatic plant or parts of a plant, with or without its natural colouring matters; and conforms in name to the plant used in its preparation.

2. The usual solvents employed in the preparation of flavouring extracts are ethyl alcohol, water, and glycerin. In the event of any other solvents than ethyl alcohol, water, and glycerin being used, such solvents shall be harmless to health, and their names shall be plainly stated on the label.

3. Solutions of natural or synthetic preparations such as vanillin, coumarin, benzaldehyde, methyl salicylate or other sapid and odorous compounds, more or less resembling substances found in plants, or absolutely identical with these, if harmless to health, may be sold for flavouring purposes, if properly labelled so as to make it quite clear that they are not extracts as above defined; and preferably by the use of the word "Artificial" or "Imitation." The word "Artificial," or "Imitation," or other equivalent word, shall appear on the label in type as large and conspicuous as that used in any other word on the label.

4. If an extract be fortified or strengthened by having such natural or synthetic preparations as are referred to in the immediately preceding section added to it, the fact of such addition shall be clearly stated on the label, or the word "compound" or "mixture" shall be used to describe it. The word "compound" or "mixture" shall appear on the label in type as large and conspicuous as that used in any other word on the label.

5. Lemon extract is the flavouring extract prepared from the lemon peel, or from oil of lemon, and contains, along with more or less of the terpenes of lemon oil, not less than 0.2% of citral derived from oil of lemon.

6. Terpene lemon extract is the flavouring extract prepared as above described, and contains not less than 5% of oil of lemon, and not less than 0.2% of citral, derived from oil of lemon.

7. Vanilla extract is the flavouring extract prepared from vanilla bean with or without sugar or glycerin, and contains in 100 c.c. the soluble matters from not less than 5 grams of the vanilla bean (the dried, cured fruit of *Vanilla planifolia*).

8. Vanilla extract shall contain no colouring matter other than that supplied by the vanilla bean itself.

9. Artificial and compound extracts of vanilla may contain added colour of harmless character, provided that declaration of such added colour be made by the use of the word "coloured" on the label, in type as large and conspicuous as that used in any other word on the label.

Composition of brewers' grains, and the dust from them. Hulton and Baker. *See* XVIII.

Determination of theobromine. Debourdeaux. *See* XX.

PATENTS.

Food products: Art of estimating solid content of liquid — J. J. Mojonniier, Oak Park, Ill., Assignor to Mojonniier Bros. Co., Portland, Me. U.S. Pat. 1,221,357, Apr. 3, 1917. Date of appl., Nov. 23, 1914. Renewed Jan. 31, 1917.

THE method consists in boiling a weighed quantity of the liquid for a few minutes at 180° C. and then evaporating it to dryness at 100° C. The residue is placed in a vacuum cooling and drying chamber, and finally is weighed.—J. H. J.

Wheat and other grains: Process of cleaning — A. C. Von Hagen, Kansas City, Mo. U.S. Pat. 1,221,636, Apr. 3, 1917. Date of appl., Mar. 3, 1916.

THE wheat or other grain is treated with powdered lime, and afterwards a small quantity of water, insufficient to dissolve the lime, is added. The wheat is then treated to remove the alkali and the material adhering to it.—J. H. J.

Bread: Manufacture of — H. A. Kohman, T. M. Godfrey, and L. H. Ashe, Pittsburgh, Pa., Assignors to Ward Baking Co., New York. U.S. Pat. 1,222,301, Apr. 10, 1917. Date of appl., Aug. 16, 1916.

A CASEIN material, such as cheese, to serve as a yeast food, is incorporated with the flour, yeast, and other ingredients of the dough.—J. H. J.

Cereals and cereal products: Method of treating — E. E. Werner, Indianapolis, Ind. U.S. Pat. 1,222,830, Apr. 17, 1917. Date of appl., May 13, 1913.

THE cereals are steeped before grinding in a liquid containing ammonium persulphate or a mixture of ammonium persulphate and phosphoric acid.—J. H. J.

Sea mammals: Method of making the meat of — fit for food. G. A. Holzapfel, Leipzig, Germany. U.S. Pat. 1,223,790, Apr. 24, 1917. Date of appl., Jan. 31, 1916. Renewed Mar. 15, 1917.

THE flesh of sea mammals is treated alternately with cold and hot water, and is then placed in a pickle of common salt, sugar, and a pungent alcoholic liquor, a savoury vegetable sometimes being added. The meat is subsequently pressed to remove excess of the pickle and extractive matters of offensive taste.—J. H. J.

Dried milk: Preparation of — Hamburger und Co., Vienna, Ger. Pat. 295,801, Oct. 5, 1913.

THE milk is passed through a narrow channel between parallel plates into a revolving drum heated externally. The channel is kept cold at the junction with the drum to prevent conduction of heat to the milk and consequent separation of solid constituents prior to its entry into the drum. By careful drying, a product is obtained with satisfactory solubility and keeping qualities.—H. J. H.

Process for preparing musts, wines, brandies, alcohols, syrups, honey substitutes, and jellies. Eng. Pat. 105,282. See XVIII.

XIXB.—WATER PURIFICATION; SANITATION.

Antiseptics: Regular and irregular — C. Richet, H. Cardot, and P. Le Rolland. Comptes rend., 1917, 164, 669–673.

THE amount of acidity produced in a culture medium by the growth of one of the lactic acid bacilli is very regular, provided all precautions are taken to have identical conditions in all the tests. If the arithmetical mean of the variations from

the mean of each test in a series be divided by the mean acidity of the whole series, a number is obtained which may be called the relative mean variation of the series. In the presence, however, of small quantities of antiseptics there are considerable differences in the numbers obtained. Thus, in a normal medium the relative mean variation is 0.089, in the same with thallium nitrate added 0.195, with mercuric chloride 0.162, with sodium fluoride 0.066, with magnesium chloride 0.063. The relative mean variation was always greater when the acidity of the culture was low, and it decreased with increasing acidity until the numbers were practically identical with all the antiseptics. The amount of antiseptic necessary to bring about a diminution of growth of 50% was difficult to determine accurately, but the differences between individual antiseptics was very marked. Sodium fluoride, magnesium chloride, and phenol gave fairly regular results; whereas mercuric chloride and sodium arsenate gave very irregular results.—J. H. J.

Antiseptics: Effect of glycerin on — H. P. Goodrich. Brit. Med. J., 1907, 617. Pharm. J., 1917, 98, 453.

RECENT experiments show that glycerin impairs the antiseptic power of thymol, phenol, boric acid, and mercuric chloride in aqueous solution. Many antiseptics, inorganic as well as organic, are much more soluble in glycerin than in water. For example, the approximate solubilities per cent. at ordinary temperatures of the following substances in water and glycerin respectively are: Thymol, 0.06, 0.526; phenol, 7.7, 350.0; mercuric chloride, 5.26, 61.5; boric acid, 4.0, 25.0. In a mixture of equal volumes of water and glycerin about five times as much thymol will dissolve as in plain water, but the resulting solution has no better antiseptic power than the aqueous solution containing only a fraction of the amount of thymol. The same applies to boric acid; a saturated solution in water will kill all the organisms on a thin film of *Staphylococcus pyogenes aureus* in just over an hour, whereas a saturated solution in water and glycerin containing more than four times as much boric acid requires about six hours. It has long been assumed that solutions in glycerin were more antiseptic than the weaker aqueous solution, but it is a fact that even water compares well in disinfecting power with 50% glycerin. Pure glycerin easily kills protozoa, but it is by virtue of its osmotic action. Dilute solutions are not even preservative. A 3.3% solution of phenol in water destroyed all the individuals in a standard culture of *S. pyogenes aureus* contained on a thin film on a cover-glass in less than a quarter of a minute; the same strength solution in water and glycerin required more than a minute. The comparative figures for mercuric chloride (0.005% solution) are $\frac{1}{4}$ and $\frac{1}{2}$ minute; for boric acid (saturated aqueous solution, i.e., 4%), 65 minutes; half saturated solution, 12 $\frac{1}{2}$ minutes; 2 per cent. solution in water and glycerin, more than 480 minutes; thymol (saturated solution), $\frac{1}{4}$ minute; half-saturated solution (0.03%), 12 $\frac{1}{2}$ minutes; same strength in glycerin and water, more than 300 minutes.

Drinking water: Disinfection of — H. D. Dakin and E. K. Dunham. Brit. Med. J., 1917, 682.

THE authors state that *p*-sulphodichloramino-benzoic acid is the most suitable substance, both chemically and bacteriologically, for disinfecting drinking water. The compound, $\text{Cl}_2\text{N}.\text{SO}_2.\text{C}_6\text{H}_4.\text{COOH}$, for which the name "halazone" is suggested, is obtained from *p*-toluenesulphonic amide, prepared by the action of ammonia on the acid chloride. The amide is oxidised to *p*-toluene-

sulphaminobenzoic acid, which on suitable treatment with chlorine is converted into the dichloro-anilino compound. The disinfectant compound may be made into tablets weighing about 0.1 gm., containing 4% of the substance, together with 4% of sodium carbonate, the remainder being sodium chloride. One tablet is usually sufficient to sterilise one litre of water, though more may be required where the contamination is excessive.

Experiments with paper tubes. Rudeloff. See V.

PATENTS.

Adding chemical reagent to water or other liquid; Apparatus for —. W. Paterson, London. Eng. Pat. 105,086, Mar. 22, 1916. (Appl. No. 4281 of 1916.)

A SHORT, somewhat tapering pipe is inserted in a vertical position in an enlarged portion of a pressure main. In the pipe is mounted a shaft carrying a weighted disc, and the lower portion of the shaft ends in a tapered extremity which passes through a slot in the bottom of the main, and acts as a by-pass. The weighted disc rises and falls proportionally with the rate of flow in the main, and by the same action the amount of water passing through the by-pass is similarly regulated. The water which is by-passed travels by a pipe into a closed reagent tank and passes on with a proportionate amount of the reagent into the main beyond the enlarged portion.—J. H. J.

Liquids; Electrochemical treatment of —. C. P. Landreth, Philadelphia, Pa. U.S. Pat. 1,222,637, Apr. 17, 1917. Date of appl., Aug. 6, 1915.

AN electric current is passed through the liquid or water containing in solution materials producing temporary hardness, and a soluble hydroxide or carbonate is introduced in excess of the amount required to react with the dissolved material, so that free alkali is present in the resulting effluent.—B. N.

Sewage; Tanks for the purification of —. T. Caink, Worcester. Eng. Pat. 105,654, May 20, 1916. (Appl. No. 7206 of 1916.)

THE apparatus is designed to be used in the purification of sewage by the activated sludge process and consists of a tank divided into several bays in series and covered with an air-tight roof. It is filled to the roof with sewage. Air is admitted along the bottom of one side of each bay, and imparts to the sewage a vertical circulatory motion, which is aided by suitable guiding baffles arranged so as to prevent deposition of solids on the floor of the bay. In another form, the tank is divided into a number of parallel bays and air is supplied along the side of the first bay only, parallel to the direction of the flow of sewage. The dividing walls between the bays have openings at the top and bottom to permit of the passage of air to and fro at right angles to the flow of the sewage. This imparts a spiral motion to the sewage in the tank.—J. H. J.

Sewage; Process for disposal of — by micro-organisms. O. F. Starr, Utica, N.Y., Assignor to E. A. Robinson, Mount Vernon, N.Y. U.S. Pat. 1,223,001, Apr. 17, 1917. Date of appl., Apr. 10, 1914. Renewed Feb. 12, 1917.

A POOL of sewage, having a non-disturbing inflow and outflow, is secluded from light, air, and agitation, until a mass of micro-organisms has been developed of a character and quantity sufficient to liquefy the solid constituents of the flowing sewage. The pool is disposed in such a manner as to provide a restricted surface area materially smaller than the cross-sectional area at the bottom of the pool, thus concentrating the action of the micro-organisms in the upper portion of the

pool, whilst at the same time gases accumulate under the surface of the pool, producing a pressure greater than the atmospheric pressure.—B. N.

Sewage; Tank for the treatment of —. H. Y. Scarborough, Minneapolis, Minn. U.S. Pat. 1,223,127, Apr. 24, 1917. Date of appl., Aug. 2, 1915. Renewed Sept. 27, 1916.

SEWAGE from a closet bowl enters the first chamber of a tank where the solids are disintegrated by bacterial action, and overflows into a second chamber from which it passes under a baffle-wall into a sterilising chamber. Before the sewage passes under the baffle, it is confined temporarily while a sterilising agent is added to it. The sterilising chamber has a siphon discharge, and the rise and fall of the liquid controls the addition of the sterilising agent.—J. H. J.

Air; Process and apparatus for purifying and re-oxygenating —. J. F. Place, Glen Ridge, N.J., U.S.A. Eng. Pat. 105,105, Mar. 29, 1916. (Appl. No. 4632 of 1916.)

THE apparatus consists of a cylindrical vessel open at top and bottom and packed with a series of wire baskets holding caustic potash or slaked lime. An electric motor and fan, for drawing air upwards through the cylinder, are placed in the opening at the top. Just below the fan is the mouth of a pipe conveying a supply of oxygen from a cylinder of the compressed gas and from a vessel containing liquid oxygen which passes through an evaporating coil before entering the supply pipe, or from one of these sources. The air from the inhabited space to be treated is drawn through the treatment vessel where its carbon dioxide and moisture are removed, and as it leaves at the top it has its volume of oxygen made up again.—J. H. J.

Insecticides or plant washes. G. J. Lemmens, Wateringbury, and P. J. Fryer, Tonbridge, Kent. Eng. Pat. 105,478, July 13, 1916. (Appl. No. 9863 of 1916.)

ARSENICAL compounds are made into a thick cream by the addition of water and a substance such as glue, starch, gluten, soaps, resin soaps, gum arabic, or nitrogenous materials. The presence of these substances causes the arsenical compound to be held in suspension when the mixture is diluted for use.—W. P. S.

Insecticides, sheep dips, animal washes, and the like. G. J. Lemmens, Wateringbury, and P. J. Fryer, Tonbridge, Kent. Eng. Pat. 105,525, Dec. 4, 1916. (Appl. No. 17,381 of 1916.)

THE seeds, leaves, and other portions of the plants known as tephrosia, particularly *Tephrosia vogelii*, are extracted with benzene, the extract is evaporated, and the residue is diluted with water (1.5 to 12 oz. per 100 galls.) to form an insecticide or sheep dip. Other ingredients may be added.—W. P. S.

Purifying liquids; Process for —. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Frankfurt, Germany. Eng. Pat. 100,638, May 12, 1916. (Appl. No. 6828 of 1916.) Under Int. Conv., June 10, 1915.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Theobromine; Determination of—, L. Débourdeaux, J. Pharm. Chim., 1917, 15, 306–311.

MAUPY'S method (this J., 1897, 611) is founded on sound and accurate principles, but owing to the fact that the theobromine precipitated by ether is contaminated by 6–12% of impurities, it cannot be recommended, as it stands, for the accurate determination of theobromine in cacao. The author has adopted this method in conjunction with a process of purification. 100 grms. of cacao is triturated with 10 c.c. of water and the moist material is introduced into a flask of 1 litre capacity with 60 grms. of solid phenol and 310 grms. of chloroform. The mixture is boiled under a reflux condenser for two hours, cooled, poured on a filter, and the residue sucked dry and washed with chloroform. The residue is then put back into the flask with 300 grms. of chloroform and 50 grms. of the above chloroform-phenol mixture and again boiled for an hour. The filtration is repeated and the residue boiled a third time with 300 grms. of pure chloroform. After standing, preferably for twelve hours, the united chloroform extract is filtered into a large conical flask and the filter washed with chloroform. The chloroform is distilled off, preferably on an electric hot-plate, and 900 grms. of ether is added to the residual phenol solution, the mixture being allowed to stand all night. The theobromine is precipitated, while the caffeine, fat, and most of the colouring matter remain in solution. The ether is decanted off, the precipitate collected on a filter, the flask and filter are washed with ether, the theobromine and filter are put back in the flask with 20 grms. of sulphuric acid and 180 of water; the liquid is boiled and filtered hot into another flask containing 250 c.c. of ammonia solution of sp. gr. 0.924. The first flask and the filter are washed with a boiling solution of 7.5 grms. of sulphuric acid and 112.5 of water and then with 150 c.c. of boiling water containing 30 drops of sulphuric acid. The ammoniacal solution is treated with 3 grms. of silver nitrate, and evaporated on the water bath until all the ammonia has been driven off. It is made up again to about 500 c.c., allowed to stand for a night, and the precipitate of the silver compound of theobromine is collected on a filter, washed with 250 c.c. of water, placed in a conical flask with 50 c.c. of water, and allowed to stand several hours in an atmosphere of hydrogen sulphide; 600 grms. of amyl alcohol is then added and the mixture slowly distilled with a Vigreux tube until about 200 c.c. of aqueous amyl alcohol has come over and the boiling point is 127–128° C. The solution remaining in the flask is filtered hot into a beaker standing in a water-bath and the flask and filter are washed twice with 100 grms. of boiling amyl alcohol. The filtrate is kept in a cool place for 12–36 hours until the theobromine has crystallised out; the alkaloid is collected on a tared filter and the filtrate is weighed in order to make a correction on the assumption that 1000 grms. of amyl alcohol at 15° C. dissolves 0.2 gm. of theobromine. The theobromine is washed with

ether, dried at 100° C., and weighed. The method is very accurate and gives results in close accordance with factory yields.—J. P. B.

Phenolic bases; Researches on—, J. von Braun and E. Danziger, Ber., 1917, 50, 286–289.

β -ACETAMINO- β -METHYLHYDRINDENE on nitrating with concentrated nitric acid is converted into *p*-nitro- β -acetamino- β -methylhydrindene, m. pt. 144° C. This on reduction with tin and hydrochloric acid is converted into the corresponding amino-compound, m. pt. 153–154° C., which on treatment with sodium nitrite in hot mineral acid solution is converted into *p*-hydroxy- β -acetamino- β -methylhydrindene, m. pt. 112° C. On hydrolysis with 20% hydrochloric acid at 120° C., the acetyl group is removed and *p*-hydroxy-amino- β -methyl- β -hydrindene, m. pt. 154° C., is obtained. *p*-Hydroxy-amino- β -methyl- β -hydrindene is not more active physiologically than amino- β -methyl- β -hydrindene and hence affords an exception to the rule that the introduction of a *para*-phenolic group results in increased physiological activity.—T. C.

Allylbetaine and allylhomocholine; Preparation and physiological properties of—, J. von Braun and E. Müller, Ber., 1917, 50, 290–293.

THE methyl ester of dimethylaminoacetic acid, obtained by the dry distillation of betaine, reacts with allyl iodide in ethereal solution forming a quaternary iodide, m. pt. 83° C., and the latter, on treatment with colloidal silver, yields allylbetaine, m. pt. 66° C., which forms a crystalline platinum salt, m. pt. 174–175° C., and a crystalline gold salt, m. pt. 116° C. γ -Hydroxypropyldimethylamine combines rapidly with allyl iodide in ethereal solution yielding the quaternary iodide, m. pt. 57–58° C. The corresponding chloride, allylhomocholine, forms a thick oil giving an oily gold salt and a crystalline platinum salt, m. pt. 182° C. As in the case of *N*-allylmorcodeine and codeine, allylbetaine and allylhomocholine have the opposite physiological effect to betaine and homocholine respectively. *N*-Allylpyrrolidine, *N*-allylthalline, 1-allyltheobromine, allylstrychnine, and diallyl sulphate do not show this reversal of physiological action.—T. C.

Acetylsalicylic acid; Some salts of—, M. Bouvet, Bull. Sci. Pharm., 1917, 24, 86. Pharm. J., 1917, 98, 419.

Sodium acetylsalicylate, or "hydropyrine," may be obtained by a modification of Richter's process (Ger. Pat. 218,467; this J., 1910, 452). A solution or suspension of acetylsalicylic acid in methyl alcohol, containing a little water, is treated with the theoretical equivalent of sodium carbonate. An excess of ether is then added, which precipitates the sodium salt. This is collected, drained, and dried at 40° C. The white salt thus obtained melts at 218° C. with decomposition. It is very hygroscopic and unstable, and rapidly hydrolysed on contact with water into sodium salicylate and acetic acid. *Lithium acetylsalicylate*, known as "hydropyrine L.," "grifa," or "apryone," has been recommended as a substitute for the more unstable sodium salt. It is, however, hygroscopic, and is difficult to prepare, generally containing not less than 5 per cent. of impurities. It forms prisms containing 0.5 mol. of water. It is hydrolysed on contact with water, but somewhat less rapidly than the sodium salt. *Calcium acetylsalicylate* is a much more stable salt than the two described above. It is not hygroscopic; is very soluble, giving clear 1:20 solutions with water, and these solutions are only slightly acid. It is the best salt for pharmaceutical use for the preparation of cachets or tablets. For this purpose it has been introduced into

commerce under the names "soluble aspirine," "kalmopyrine," and "solupyrine." It is best prepared by Mathé's process: Pure lime is slaked with water, suspended in alcohol, and treated with the theoretical amount of acetylsalicylic acid in gradually increasing concentration in alcoholic solution. The pinkish mass obtained is pressed, washed with ether, and dried at 40° to 50°C. Thus obtained it contains 2 mols. of water, of crystallisation, is readily soluble in water, less soluble in alcohol, and insoluble in ether. It may also be obtained in needles, containing 3 mols. of water. It has a slightly chalky taste. According to Gerngross (Fr. Pat. 464,081; this J., 1914, 439), the use of organic solvents for the preparation of this and similar salts of acetylsalicylic acid is unnecessary; better results are obtained with aqueous solutions. *Magnesium acetylsalicylate* is easily obtained by agitating together calcined magnesias, 4 grms.; acetylsalicylic acid, 36 grms.; and water, 189 grms.; then adding methyl alcohol, and precipitating the salt with ether. *Magnesium acetylsalicylate* is soluble in water and in methyl alcohol, less soluble in ethyl alcohol. It crystallises from aqueous solutions in hexagonal tables containing 3 or 4 mols. of water. Among the other little known acetylsalicylates the following are mentioned:—*Potassium*, forming tables, m.p.t. 65°C.; *zinc*, rhombic tables sparingly soluble in water and in alcohol; *copper*, prisms, insoluble in water and in alcohol; *silver*, needles, insoluble in water; and *mercury*, crystallising from aqueous solutions with 1 mol. of water, m.p.t. 136°C. with decomposition; from chloroform it crystallises in anhydrous prisms, m.p.t. 142°C. with decomposition. It is claimed for the calcium salt that it does not cause pharyngeal or gastric pain like the free acid, and that it occasions less renal irritation, while it has all the therapeutic properties of acetylsalicylic acid.

Ethylene; Action of bromine water on —. J. Read and M. M. Williams. Chem. Soc. Trans., 1917, 111, 210—244.

The action of bromine water on ethylene at 0°C. yields ethylenebromohydrin as well as ethylene dibromide. In one experiment where ethylene was passed into 500 c.c. of water, to which successive quantities of 7.2 grms. of bromine were added amounting to 200 grms. in all, the yields were 88 grms. of dibromide and 85 grms. of bromohydrin. The yield of bromohydrin is diminished by rise in temperature, and by an increase in the concentration of the bromine water. Attempts to increase it by adding calcium carbonate or sodium bicarbonate to the water were not successful, owing to the greater amount of decomposition of hypobromous acid into hydrobromic acid and water. Ethylene bromohydrin appears to form a crystalline addition compound with calcium chloride, but the ease with which it is decomposed by moist air makes a determination of its composition very difficult.—W. H. P.

Sozoiodol-mercury compounds. E. Rupp and A. Herrmann. Arch. Pharm., 1917, 254, 488—500. Z. angew. Chem., 1917, 30, Ref., 69.

The solubility of sozoiodol-mercury in sodium chloride solution is due to formation of mercuric chloride; the existence of the acid salt or simple sulphonate is considered to be improbable. In the interaction of sozoiodol-sodium with mercuric acetate or nitrate, the precipitate formed is at first dark red and then orange-coloured; the red intermediate product has been isolated. In the first stage of the reaction, combination takes place at the free hydroxyl group, whilst afterwards the sodium combined with the sulphy-group is displaced by mercury. It is considered to be

highly probable that sozoiodol-mercury has a binuclear structure, but for practical purposes the mononuclear formula may be retained. The chromophor in sozoiodol-mercury is the O.OH group. Sozoiodol when heated with hydrochloric acid in a sealed tube yields 2,4,6-tri-iodophenol, phenol, and iodine. By the action of chlorine water-dimercuphenol-*p*-sulphonic acid is converted into 2,6-dichloroquinone, whilst iodine solution converts it into sozoiodol.

Mercurised derivatives of p-phenolsulphonic acid. E. Rupp and A. Herrmann. Arch. Pharm., 1917, 254, 500—509. Z. angew. Chem., 1917, 30, Ref., 69.

HYDRARGYROL is described as mercuric *p*-phenol-sulphonate, but a product prepared according to the process described originally had properties different from those of hydrargyrol, hence the latter must have another constitution; possibly it is a derivative of phenol-*o*-sulphonic acid. The chief product formed by mercurising phenol-*p*-sulphonic acid is dimercuroxyphenol-*p*-sulphonic acid, whether 1 or 2 mols. of mercuric oxide is used. When 1 mol. is used, a small quantity of a colourless, crystalline monomeric phenol-*p*-sulphonate is formed. With 3 mols. of mercuric oxide, the mercuric salt of the dimercuro-derivative is formed.

Camphor oil from the Federated Malay States and Mauritius. Bull. Imp. Inst., 1916, 14, 577—585.

FURTHER samples of camphor oil from the Federated Malay States and Mauritius (see this J., 1913, 505; 1916, 274) have been examined at the Imperial Institute. The former are found to differ in the same way as previous samples from ordinary commercial camphor oil in that the camphor has not been separated from them, and that they contain no safrole. Their commercial value, is, however, about the same, the absence of safrole being compensated by the camphor present. The Mauritius samples, which were obtained from leaf, twig, root, and wood respectively, were abnormal in character and did not resemble commercial camphor oil; no solid camphor was obtained from them, and subsequent distillation trials in Mauritius showed that the trees, which are genuine *Cinnamomum camphora*, Nees, do not yield solid camphor on distillation.

—E. W. L.

Cnidium officinale; Essential oil of —. Sakei. Mitt. Med. Ges., Tokyo, 1916, 6, 358. Perf. Ess. Oil Rec., 1917, 8, 174.

Cnidium officinale is an umbelliferous plant the root of which is used medicinally in China and Korea. The active principle is an essential oil of which the specimen of drug examined yielded 0.82%. It is a yellow laevo-rotatory liquid, having a bitter taste; its sp. gr. is 1.030 to 1.040. It contains an unsaturated acid, $C_{12}H_{19}O_3$; an alcohol, $C_{16}H_{25}O_3$; and another constituent possibly a lactone, $C_{12}H_{18}O_2$.

Bay oil; Montserrat —. H. A. Tempany. Perf. and Ess. Oil Rec., 1917, 8, 160.

SAMPLES of bay oil from Montserrat distilled in 1916 had sp. gr. varying from 0.926 to 0.910 at 30°—31° C. (corresponding to 0.938 to 0.952 at 15° C.), and phenol content varying between 46% and 54%. The author sees no correlation between phenol content and date of distillation, nor between phenol content and yield of oil.

Terpenes; Autoxidation of — in the light. II. E. Sernagiotto. Gazz. Chim. Ital., 1917, 47, I., 150—153.

PULEGONE was exposed for 1 month to the light in flasks containing oxygen and some water, and

the liquid portion then distilled in a current of steam. The distillate contained acetone, formic acid, and traces of higher fatty acids. The liquid residue in the flask when made alkaline with sodium carbonate and extracted with ether yielded the crystalline lactone of a ketonic acid, $C_{10}H_{14}O_5$, which melted at $183.5^\circ C.$ and formed an oxime melting at $116^\circ C.$ When oxidised with chromic acid, it yielded a crystalline acid, β -methylglutaric acid (m. pt. $86.7^\circ C.$), together with some acetone. The alkaline residue from the ether extraction was a viscous brown oil, from which was separated an acid melting at $84^\circ C.$ and having the composition of β -methyladipic acid, $C_7H_{12}O_4$, and an acid, $C_{10}H_{18}O_5$, of unknown constitution.—C. A. M.

Carrone; Products of the isomerisation of — in the light. E. Sernagiotto. Gazz. Chim. Ital., 1917, 47, I., 153—159.

The solid isomeride of carvone (carvone-camphor) which Ciamician and Silber (this J., 1908, 711) obtained by exposing a dilute alcoholic solution of carvone to the light for several months, melts at $100^\circ C.$ and boils at $206.5^\circ C.$ When oxidised with alkaline potassium permanganate solution it yields a dibasic acid, $C_{10}H_{14}O_4$, soluble in petroleum spirit and melting at $171^\circ C.$, and a monobasic ketonic acid (m. pt. $196^\circ C.$), $C_9H_{12}O_3$, which is insoluble in petroleum spirit. On treating carvone-camphor in alcoholic solution for some days with sulphuric acid, and distilling the mixture in a current of steam a liquid isomeric derivative, isocarvone-camphor, $C_{10}H_{14}O$, is obtained. This distils at 222° — $221^\circ C.$, and forms an oxime melting at $167^\circ C.$ and a semicarbazone melting at $209^\circ C.$ By reducing carvone-camphor by means of sodium in alcoholic solution, it yields the corresponding alcohol, carvone-borneol, $C_{10}H_{16}O$, which melts at $135^\circ C.$ and yields a semicarbazone melting at $239^\circ C.$ —C. A. M.

Chemical nature of vitamins. Structure of the curative modifications of the hydroxypyridines. Williams. See XIXA.

Sodium perchlorate as a general microchemical reagent. Demigès. See XXIII.

PATENTS.

Acetic anhydride; Manufacture of —. H. Dreyfus, Basle, Switzerland. Eng. Pat. 100,350, May 8, 1916. (Appl. No. 6583 of 1916.) Under Int. Conv., April 19, 1915.

IN the manufacture of acetic anhydride by treating sodium acetate with sulphur chlorides, the evolution of sulphur dioxide and the formation of chlorinated by-products may be avoided by: (a) using the reagents in the proportion of 6 atoms of chlorine to 8 acetyl groups; (b) employing a diluent such as acetic anhydride; (c) maintaining a temperature below 10° — $15^\circ C.$, and preferably below $0^\circ C.$, until all the sulphur chloride has been added. Sulphur may be removed from the product by heating it with compounds of metals which form sulphides in the presence of acetic acid, e.g., oxides or acetates of lead or copper, or it may be oxidised to sulphuric acid by permanganates, nitric acid, or nitrates. *Example:*—A mixture of 720 kilos. of dry pulverised sodium acetate and 600 kilos. of acetic anhydride is cooled below $0^\circ C.$, and 306 kilos. of sulphur dichloride is gradually introduced, the temperature being maintained at about $0^\circ C.$, and the mixture being continually stirred. When all the sulphur dichloride has been added, stirring is continued for some time, and the acetic anhydride is then

distilled off, preferably *in vacuo*. The product is heated with a small quantity of copper oxide until free from sulphur.—F. Sp.

Nucleic acid or nucleates; Manufacture of —. W. B. Bottomley, London. Eng. Pat. 105,166, June 21, 1916. (Appl. No. 8914 of 1916.)

AN alkaline extract of peat, such as is obtained in the preparation of humic acid, contains also nucleic acid, which is, however, too soluble to be precipitated with the humic acid on acidification. After separation of the humic acid, or without this separation if the mixture of acids is required, the nucleic acid may be separated by concentrating the liquid to about one-twentieth of its volume and then acidifying with hydrochloric acid and sodium acetate. If the peat is extracted with a solution of an alkali bicarbonate the humic acid is not extracted. Heating the mixed peat and alkali solution to about $100^\circ C.$ by passing in live steam at 60 lb. pressure increases the yield of nucleic acid.—B. V. S.

Sodium phenate [pheno.cide]; Manufacture of —. W. Everitt and Co., Ltd., and W. Everitt, Southall, Middlesex. Eng. Pat. 105,611, Apr. 19, 1916. (Appl. No. 5739 of 1916.)

IN the manufacture of sodium phenoxide by heating together equivalent quantities of phenol and caustic soda, with about 5% of sodium sulphite, to 250° — $280^\circ C.$, the reaction is carried out in a grinding ball-mill (see Eng. Pat. 105,614, page 584), preferably provided with one hollow trunnion to allow of the escape of steam or the introduction of a thermometer, and when the evolution of steam has ceased, the product is cooled *in vacuo*, to prevent absorption of water.—F. Sp.

Sodium salicylate; Manufacture of crude —. W. Everitt and Co., Ltd., and W. Everitt, Southall, Middlesex. Eng. Pat. 105,612, Apr. 19, 1916. (Appl. No. 5740 of 1916.)

IN the manufacture of crude sodium salicylate from sodium phenoxide and carbon dioxide, a charge of sodium phenoxide is placed in a rotating autoclave, and carbon dioxide is introduced, preferably through a hollow trunnion, avoiding undue heating. When absorption has nearly ceased, the pressure of the carbon dioxide is increased to 100 lb. per sq. in. or more, for some hours. The gas supply is then interrupted, and the autoclave is heated to 120° — $140^\circ C.$ until conversion is complete.—F. Sp.

Salicylic acid; Manufacture of —. W. Everitt and Co., Ltd., W. Everitt, and C. G. Jackson, Southall, Middlesex. Eng. Pat. 105,613, Apr. 19, 1916. (Appl. No. 5741 of 1916.)

PURE white salicylic acid is produced by passing a faintly acid hot solution of crude sodium salicylate through masses of intermingled zinc and decolorising charcoal. *Example:*—Crude sodium salicylate is dissolved in nine times its weight of water and the solution is made faintly acid with sulphuric acid. It is first pumped through a column over granulated zinc, and then heated to 80° — $100^\circ C.$ and passed through a tower containing the mixed charcoal and zinc, e.g., 95% of charcoal and 5% of zinc. The tower may consist of flanged sections bolted together, containing masses of zinc and charcoal separated by partitions of moleskin fabric. The liquor passing from the tower yields pure white salicylic acid on acidification.—F. Sp.

Arylalkylhydantoins: *Manufacture of* ——. O. Inray, London. From Farbw. vorm. Meister, Lucius, u. Brünig, Höchst, Germany. Eng. Pat. 105,719, Oct. 25, 1916. (Appl. No. 15,203 of 1916.)

ARYLALKYLHYDANTOINS of the general formula,

are produced in the same way as other hydantoins or cyclic ureides, starting from arylalkylamino-acetic acids, or causing the latter to be produced during the process. They are therapeutically valuable on account of their hypnotic action. Eight methods of preparation are described. *Examples*:—(1) 20 parts of α -phenyl- α -aminobutyric ester is neutralised with dilute hydrochloric acid, and a concentrated solution of 8 parts of potassium cyanate is added. After standing for a short time, the solution is boiled. Phenylethylhydantoin separates, and is recrystallised from dilute alcohol. It melts at 198° C., is readily soluble in acetone, alcohol, and glacial acetic acid, but insoluble in water and benzene. It forms soluble alkali and alkaline-earth salts. (2) A solution of 2.3 grms. of sodium in 30 grms. of ethyl alcohol is added to 15.6 grms. of phenylcyanacetamide dissolved in 250 c.c. of alcohol. 11 grms. of ethyl bromide is added, and the mixture is boiled for 2—3 hours. On evaporating the alcohol and adding water, phenylethylcyanacetamide (m.pt. 120° C.) is precipitated. 19 grms. of phenylethylcyanacetamide is introduced with constant stirring into a hypobromite solution made from 16 grms. of bromine, 38 grms. of 35% caustic soda lye, and 400 c.c. of water. When the amide has dissolved, the mixture is heated to 40° C., and then cooled. 10 c.c. of a 38% solution of sodium bisulphite is added, and the phenylethylhydantoin is precipitated by acidifying with hydrochloric acid. Phenylmethylhydantoin melts at 193° C., piperonylmethylhydantoin at 192°—193° C., and *p*-chlorophenylethylhydantoin at 212° C. —F. Sp.

Cephaeline amyl ethers and salts thereof: *Preparation of* ——. J. W. Meader, Indianapolis, U.S.A. Eng. Pat. 105,722, July 18, 1916. (Appl. No. 16,037 of 1916.) Addition to Eng. Pat. 103,881, Feb. 21, 1916 (this J., 1917, 402).

CEPHELINE amyl ethers other than the iso-amyl ethers which form the subject of the principal patent, are produced by treating cephaeline with an alkali metal and an amyl halide. The process is the same as described in the principal patent, and the product has similar properties.—F. Sp.

Kelones: *Manufacture of* ——. G. Schicht Act.-Ges., and A. Grün, Aussig, Ger. Pat. 296,677, May 5, 1915. Under Int. Conv., May 27, 1914. Addition to Ger. Pat. 295,657 (this J., 1917, 569).

MONOCARBOXYLIC acids of b. pt. above 300° C. are heated in the liquid state in iron vessels without the addition of catalysts. *Example*: By heating technically pure stearic acid of m. pt. 68° C. for three hours to 295° C., a quantitative yield of technically pure stearone free from acid and of m. pt. 84.6° C. is obtained. It is not necessary to provide for the continuous removal of the carbon dioxide and water, as might be expected; it is preferable to carry out the operation in an autoclave.—F. W. A.

Lipoid-like nitrogen-containing compound from blood: *Preparation of a* ——. Soc. Chem. Ind. in Basle, Switzerland. Ger. Pat. 296,678, Mar. 16, 1916. Addition to Ger. Pat. 295,840 (see Eng. Pat. 11,215 of 1915; this J., 1916, 72).

INSTEAD of extracting the blood with strong

alcohol, as in the chief patent, benzene or toluene or similar solvent, in which the extract is more soluble, is used. The greater part of the solvent is distilled off from the resulting solution and the residue mixed with water and again extracted with chloroform, carbon tetrachloride, benzene, or toluene.—B. V. S.

Calcium acetylsalicylate: *Manufacture of* ——. A. Busch, Brunswick, and R. Lauch, Assignors to J. A. Wülfing, Berlin, Germany. U.S. Pat. 1,225,407, May 8, 1917. Date of appl. June 9, 1915.

SEE Eng. Pat. 100,343 of 1916; this J., 1916, 914

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Colour photography and kinematography. C. F. Jones, San Francisco, Cal., U.S.A. Eng. Pat. 105,350, Apr. 7, 1916. (Appl. No. 5130 of 1916.)

Two negatives are taken, No. 1 through a red screen and No. 2 through a green screen. A positive from No. 1 is made on paper or a transparent support and toned blue. This is then re-sensitised with a solution of bichromate containing a yellow dye, dried, exposed under a positive from No. 2 on a transparent support, and developed, etc., as usual. The super-position of the yellow dye on the blue-toned print gives the desired green print. This is finally stained with a solution of a red dye, the absorption of which varies inversely with the hardening due to the exposure behind positive No. 2.—B. V. S.

Selenium toning bath for photographic silver prints. Chem. Fabr. auf Actien, vorm. E. Schering, Ger. Pat. 296,009, Jan. 24, 1914. Addition to Ger. Pat. 280,679.

By the addition of more sodium sulphite, up to 30 grms. per litre, to the toning bath mentioned in the chief patent (sodium thiosulphate 100 grms., sodium selenosulphate 1.5 grms., sodium sulphite 13 grms., water 1 litre), a combined fixing and toning bath is obtained producing no yellowing of the whites.—B. V. S.

Paper for photographic uses: *Coating material for* ——. G. W. Leighton and C. S. Babcock, Chicago, Ill. U.S. Pat. 1,225,146, May 8, 1917. Date of appl. May 10, 1909.

SEE Fr. Pat. 418,906 of 1910; this J., 1911, 1109.

XXII.—EXPLOSIVES; MATCHES.

Propagation of flame in mixtures of acetone and air. Wheeler and Whitaker. See II A.

PATENTS.

Explosive material: *Compressors for bundled* ——. Sabulite (Great Britain), Ltd., and W. H. McCandlish, London, and A. B. Robson, Ware, Herts. Eng. Pat. 105,794, Apr. 26, 1916. (Appl. No. 5980 of 1916.)

Means applicable for use in drying materials in vacuo. Eng. Pat. 105,617. See I.

XXIII.—ANALYSIS.

Ammonia: *Micro-titration of* ——. G. D. Barnett, J. Biol. Chem., 1917, 29, 459—162.

TEN c.c. of the solution to be tested is placed in a

test-tube (22 by 380 mm.), 10 c.c. of saturated potassium carbonate solution, free from ammonia, is added, and, after the test-tube has been connected with a larger one (30 by 110 mm.) containing a measured volume (less than 0.5 c.c.) of *N* 100 hydrochloric acid and 15 c.c. of distilled water, a current of air is drawn through the apparatus for 20 mins. at the rate of 5 litres per min. The excess of acid in the absorption test-tube is then titrated with *N* 200 alkali solution added from a 1 c.c. micro-burette; methyl-red is used as the indicator. The tube connecting the two test-tubes may contain a plug of cotton-wool to prevent any alkaline spray from passing over into the second test-tube. —W. P. S.

Mercury salts; Detection of traces of — for toxicological purposes. K. C. Browning. Chem. Soc. Trans., 1917, 114, 236–240.

THE method recommended consists of electrolysis of the solution to be examined, with subsequent spectroscopic examination of the cathode. Of the various metals available for the cathode, gold foil is most sensitive, silver gauze being next best. These metals as obtained "pure" from Kahlbaum always give a strong mercury spectrum unless previously purified by heating to about 900 °C. for some time. No advantage was observed in using electrodes larger than 1.5 cm. by 0.65 cm. Conditions of electrolysis depend on the amount of solution available. If only about 10 c.c. can be obtained, 10 to 15 minutes at 0.2 ampère, without stirring, is sufficient. With larger quantities (200 c.c.) 2 ampères may be used, with rapid stirring, but care must be taken to avoid loss of mercury by heating of the solution, which takes place if electrolysis is prolonged. The cathode is washed with water and placed in one limb of a Dupré tube. This limb is heated to 200–250 °C. in an oil bath. The tube is exhausted by a Gaede oil pump, washed out with hydrogen, and again exhausted. The discharge is passed from a moderately strong coil (15 cm. spark) and the spectrum examined by a direct vision spectroscope. With only 10 c.c. of solution, one part of mercuric chloride in one hundred million parts of solution can be detected in this way. Solutions of this concentration lose mercury on evaporation and cannot be satisfactorily concentrated. If kept in glass or quartz vessels they lose mercury by adsorption on the walls of the vessel, from which it can be recovered by washing a few times with concentrated nitric acid. —W. H. P.

Sodium perchlorate as a general microchemical reagent. G. Denigès. Bull. Trav. Soc. Pharm. Bordeaux, 1917, 5. J. Pharm. Chim., 1917, 15, 322–323.

SODIUM perchlorate has been recommended as a microchemical reagent for cocaine; it is now found that the same salt gives sparingly soluble compounds with many other substances, most of which can be identified by their characteristic crystalline forms. Many of the alkaloids, notably those of the strychnine and morphine series, can be identified microchemically by their perchlorates; also certain metals, such as potassium, rubidium, and caesium, give sparingly soluble perchlorates, whereas lithium, ammonium, and thallium do not. Precipitates are obtained with soluble salts of tropacocaine, berberine, narceine, cotarnine, and papaverine (non-crystalline at first). A concentration of 5–10% is advisable in these cases. Salts of morphine give a precipitate at 1% concentration. Brucine and especially strychnine solutions give crystalline precipitates at very low concentrations (0.2–0.1%) when the sides of the vessel are rubbed with a

glass rod. Veratrine and narcotine in dilute acetic acid solution give non-crystalline precipitates having the appearance of fat-globules. —J. F. B.

Estimation of toluene and benzene in coal-tar oils. Harker. See III.

Fastness of dyestuffs. Standards and processes established by the "Echtheitskommission." Heermann. See IV.

Determination of volatile "thinners" in oil varnishes. De Waele and Smith. See XIII.

Determination of resin in rosin size. Heuser. See XIII.

Humic acid and tannic acid. Moeller. See XV.

Relation between the indications of several lime-requirement methods and the soil's content of bases. Schollenberger. See XVI.

Ammonifiability versus nitrifiability as a test for the relative availability of nitrogenous fertilisers Lipman and Burgess. See XVI.

Determination of alcohol. Fonyo. See XVIII.

Determination of theobromine. Débourdeaux. See XX.

PATENTS.

Carbonic-acid indicator. A. Frisak, Woodbury, N.J. U.S. Pat. 1,223,953, Apr. 24, 1917. Date of appl., Jan. 6, 1917.

A VESSEL containing caustic soda is closed at the top by a stopper, through which an inlet tube for the gases extends and terminates in a horizontal curved portion just below the stopper. The outlet tube extends into the vessel nearly to the surface of the caustic soda solution and both tubes are provided with stopcocks. One limb of an inverted U-tube communicates with the vessel and the other end dips into a vessel of mercury provided with a vented stopper. A scale is provided adjacent to the latter limb of the U-tube, which enables the diminution in pressure in the vessel due to absorption of carbon dioxide to be determined. —W. F. F.

"Noble" gases [argon, etc.] and nitrogen; Apparatus for determination of — by a gas-analysis method. R. Brandt, Ludwigshafen. Ger. Pat. 296,115, May 16, 1915.

A MIXTURE of argon, etc., with nitrogen, hydrogen, carbon oxides, methane, and such gases is treated, in a tube connected with a manometer and a two-way tap, with metallic calcium in the form of large crystals, or with alloys of calcium with magnesium and aluminium, and with calcium nitride. The former absorbs all nitrogen and the latter absorbs hydrogen, methane, etc., at temperatures between 200° and 650° C. —B. V. S.

Testing materials by impact: Apparatus for —. W. and T. Avery, Ltd., A. W. Brown, and E. A. Allent, Birmingham. Eng. Pat. 105,669, June 16, 1916. (Appl. No. 8487 of 1916.)

Art of estimating solid content of liquid food products. U.S. Pat. 1,221,357. See XIXa.

Depreciation = 25.9% on cost.

To the Members of the Society of Chemical Industry.

We have audited the above Balance Sheet, dated 31st December, 1916, and have verified the investments and the Bank overdraft. In our opinion the Balance Sheet shows correctly the position of the Society at 31st December, 1916.

28, Regent's Hall Street, London, E.C.1

(Signed) FRANK B. CO.

Official Notices.

ANNUAL GENERAL MEETING, 1917.

In accordance with the provisions of By-law 64, notice is hereby given that the Annual General Meeting will be held in The University Buildings, Edmund Street, Birmingham, at 10.30 a.m. on Wednesday, July 18th, 1917. A programme of the proceedings was inserted in the June 15th issue.

In accordance with the provisions of By-law 24, those members whose names are printed in *italics* in the List of Council in the April 30th issue of the Journal will retire from their respective offices at the forthcoming Annual Meeting.

Prof. Henry Louis has been nominated to the office of President under By-law 20; Dr. Charles Carpenter has been nominated Vice-President under By-law 20; Mr. John Gray, Mr. A. R. Ling, Prof. R. F. Ruttan, and Mr. J. T. Wood have been nominated Vice-Presidents under By-law 24.

Mr. A. G. Bloxam, Mr. W. J. Rees, Mr. Edwin Thompson, and Prof. James Walker have been nominated to fill the four vacancies among Ordinary Members of Council, under By-law 25. No ballot will be required.

J. P. LONGSTAFF,
Secretary.

REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY.

The first volume of these reports is now ready. As the issue is strictly limited, those who desire to obtain copies are advised to apply for them without delay. The price is 3s. to members and 5/6 to non-members, including postage.

DYES DEPARTMENT OF THE BOARD OF TRADE.

In order to promote the further development of the dye-making industry in the United Kingdom, the President of the Board of Trade has decided to establish a special temporary Department of the Board of Trade to deal with matters relating to the encouragement, organisation, and, so far as necessary, the regulation of that industry. The Department will be under the direction of Sir Evan Jones, Bart., M.I.C.E., who will have the official title of Commissioner for Dyes. The Commissioner will act in close consultation with the various dye-making and dye-using interests concerned. Any communications on the subject should be addressed to:—Commissioner for Dyes, Board of Trade, 7, Whitehall Gardens, London, S.W.1.

CHEMICAL TRADE CONFERENCES.

The Director of the War Trade Department has agreed to arrange for regular conferences to be held at stated intervals at the Department's offices to discuss matters of interest to the chemical trade in much the same way as questions connected with the wool trade have been discussed at conferences for some time past. Lord Emmott has suggested that the best procedure is for the Chamber of Commerce interested to submit to the Department at the beginning of each month a summary of the subjects which are important enough to bring up at a conference, specifying the particular chemical, drug, or dye which they desire to discuss. If the list of subjects is of sufficient magnitude and importance to make a conference of undoubted

interest to all parties, the conference would be convened; if not, the matter would be dealt with by direct correspondence with the Chambers concerned.

FRANCE: PROHIBITED EXPORTS.

A French Presidential Decree, dated the 29th May, prohibits the exportation and re-exportation from France, as from 1st June, of acetic anhydride, animal black, insulating materials other than rubber (the exportation of rubber was already prohibited), metallic formates, oxalates, sulphites and hyposulphites, ores of strontium and of lithium, preparations derived from sabadilla seeds, quillaia bark (*Quillaia saponaria*), soda lime, sulphate of baryta (barytine) and of magnesia, uranium, zirconium and zircon, quillaia bark may however be exported and re-exported from France, without special authorisation, when consigned to the United Kingdom, the British Dominions, Colonies, and Protectorates, and certain other countries.

SULPHATE OF AMMONIA PRICES.

The Food Production Department of the Board of Agriculture draws attention to the advantages to be obtained from ordering sulphate of ammonia at once. Prices have been arranged with the manufacturers for the season ending 31st May, 1918, in such a way as to give an advantage of £1 per ton to those who purchase before the end of September.

(1) The terms and conditions which will be applicable to the sale of sulphate of ammonia, 24½% basis, in makers single bags, net cash delivered to consumer's station in any part of the United Kingdom, in quantities of not less than two tons, are:—

For orders placed with makers for delivery during the following periods:—

(a) 1st June, 1917—30th September, 1917, £15 7s. 6d. per ton. For this first period orders for 60 tons and upwards are to be placed by the 20th June for delivery in Great Britain, and by the 10th July for delivery in Ireland. Delivery in Great Britain must be in four equal monthly quantities, and in Ireland in three equal monthly quantities. Smaller quantities must be ordered before the 15th September.

(b) 1st October, 1917—31st December, 1917, £15 15s. per ton. For this period orders for 60 tons and upwards must be placed by the 10th September for delivery in three equal monthly quantities either for Great Britain or Ireland. Smaller quantities must be ordered by the 10th of each month for delivery during that month.

(c) 1st January, 1918—31st May, 1918, £16 7s. 6d. per ton. For this period all orders, large and small, must be given by the 10th of each month for delivery during that month.

The foregoing prices are subject to a discount for cash of 10s. per ton to manure mixers, agricultural merchants and dealers and co-operative societies.

(2) Quantities of less than 2 tons will be supplied at the above rates, provided they form part of a bulked order of not less than 2 tons, so as to facilitate railway transport and avoid the wasteful use of trucks.

(3) Where the purchaser takes delivery at the maker's works for conveyance otherwise than by rail the price will be 10s. per ton less. For sulphate of ammonia of a higher or lower quality a difference of 3s. 3d. per ton is to be allowed in respect of each quarter per cent. above or below 24½%.

Fractional differences of less than a quarter per cent. will not be taken into account. Where makers require purchasers to provide their own bags the actual cost of bags at the time of delivery shall be allowed.

(1) The net cash retail prices of sulphate of ammonia to consumers, in quantities under two tons, for delivery in Great Britain by dealers or store or by makers or works, shall not exceed the following:—

	Quantities of 28 lb. and less than 1 cwt.	1 cwt. and less than 2 cwt.	2 cwt. and less than 1 ton.	1 ton and less than 2 tons.
	per cwt.	per cwt.	per cwt.	per ton.
1st June, 1917, to 31st Dec., 1917	20s.	18s.	17s.	£16 10s.
1st Jan., 1918, to 31st May, 1918	21s.	19s.	18s.	£17 5s.

No additional charge to be made for excess over 24½% basis in respect of these small quantities.

Dealers and farmers, if unable to obtain supplies from local works, should apply to the Sulphate of Ammonia Distribution Committee, Food Production Department, 72, Victoria Street, London, S.W.1.

Glasgow Section.

Meeting held at Glasgow on Tuesday, 27th February, 1917.

MR. JAMES MACLEOD IN THE CHAIR.

LOW TEMPERATURE CARBONISING AND SOME PRODUCTS.

BY ROBERT MACLAURIN.

My early oil work experience at Stanrigg convinced me that non-coking coals could be successfully carbonised without any external heating, and if a method could be devised of preventing the condensing oils from trickling down into the hot producer zones, coking coals, I considered might also be dealt with. This hoped was largely based on Percy's statement that coals when slowly heated lost their power of coking. After many elaborate schemes had been drawn out, the present simple method gradually evolved (see Collar C, Fig. 1). The scheme was put before Bailie W. B. Smith, convener of the Smokeless Fuel Committee of the Glasgow Corporation, and Mr. Lackie, head of the Electricity Department. After consideration by the Gas and Electricity Committees it was agreed to undertake an experiment jointly. I must here record my indebtedness to Bailie Smith, to the members of both committees, to the Corporation of Glasgow, and to the heads of the Electricity Department, and the Staff at Port Dundas, for their help and courtesy.

The plant as erected with the compartments A and B (Fig. 1) was intended to be used for two purposes. One of these was for the production of smokeless fuel and illuminating gas, and the other for the production of power-gas—both with oil and ammonia as by-products.

Power gas.

For the production of power gas, air and steam were blown into compartment A, by passage E, indicated by dotted lines, and the gas passed up through the fuel, carbonising it and distilling off the oils. The heavier oils condensed, and ran

down to the collar where they were trapped and overflowed along the pipe, G, to the seal tank, S. Here the heavier oils were left, and the gases ascended through the first scrubber, where they met a very fine spray of water, containing about 1% of free sulphuric acid; from this they entered the second scrubber, in which they were intended to be treated with a shower of heavy oil, to abstract the lighter oils, though this was never put into use. From this scrubber they were drawn by a Sirocco fan, and passed to burners, where they were burnt under a water-tube boiler. The quantity and quality of power gas made depended entirely upon the fuel used and the quantity of steam passed. Addition of fresh fuel was not traceable by any change of quality in the gas. This was anticipated, for the fresh fuel is supplied on to the top of fuel, the temperature of which is probably not above 100° C. A fairly uniform power gas is therefore easily maintained, and as there is no destruction of the oils, the gas is perfectly free from stringy masses of tar. The length of producer enables the carbon in the fuel to be burned practically completely. With the coals tried, clinkering difficulties hardly appeared, although the steam used was occasionally very low. When working steadily we aimed at a saturation at 70° C.

The following is a typical analysis of the power gas made: CO₂ 12.9%, O₂ 0.9, C₂H₄ 0.2, CO 5.6, CH₄ 10.0, H₂ 8.9, N₂ 61.5%. Calculated heating value = 134 B.T.H.U. per cub. ft.

Smokeless fuel.

The manufacture of smokeless fuel, contrary to expectation, worked smoothly. The fuel came down regularly and was thoroughly carbonised. No matter the size of the coal used, it was always uniformly coked from outside to centre.

Working for smokeless fuel I anticipated getting from 10 to 12 cwt. per ton of coal, about 10,000 cubic feet of gas of about 550 B.T.H.U., from 15 to 25 gallons of oil, and a yield of ammonia at least equal to gas-works practice. The estimate for the coke was made on the assumption that about 2 cwt. of the coal would require to be burned to ash to carbonise one ton of coal. To prevent this ash being mixed with the smokeless fuel, the furnace was made with two compartments. The coal was to be carbonised in compartment A, and the hot power gas was to be made in compartment B, Fig. 1.

In the first trials cannel coals were used and gave no trouble, but the quantity of ash in the fuel was too high for domestic use. A coking coal was next tried, and was used at first just as delivered, i.e., large and small mixed. The downward progress of the fuel was carefully watched—by its effect on the pressure gauges—and before any serious trouble arose we recognised that the quantity of fine coal was too great, and thereafter the fine was riddled out. Later we found that riddling was only necessary when a large quantity of dross was present. Good screened coal presented no trouble. Only twice in the course of a year's experimenting after this had we any occasion to poke down the fuel—and in both cases the necessity arose from starting with a half empty producer, and filling up the empty internal hopper too rapidly.

The first coke, from Cadder coking coal, unriddled, showed evidence of the fine dust binding the coal into large masses; this we only once experienced. When excessive dross was riddled out, the coke retained in the main the shape and size of the coal going in. It is, however, very much harder than the original coal, and some of it is very hard indeed.

Dr. Marie Stopes has examined under the microscope samples of the coke obtained at different levels of the furnace, and has been able

Maclaurin producer.
FIG. 1.

to trace the organic structure of the original coal, down into the regions where a medium temperature must have existed, then follows a very sharp change in which the original structure disappears. Unfortunately the temperature for each sample examined was not known, but I hope to be able to determine this exactly at a later date. Evidently, the coal under the slow heating to which it is subjected does not intumesce, and by the time it reaches the hotter regions, where a definite structural change takes place, it has lost the power of doing so.

Three coals have been coked in the producer so far; these are Tannochside cannel, Cadder coking coal, and Greenhill coking coal. The analysis of the coals and the dried coke is shown in the accompanying table and for comparison there is shown alongside an analysis of gas work coke obtained at the high temperature of

	Water. %	Volatile matter. %	Carbon. %	Ash. %
Cannel coal	10.70	30.72	46.51	12.17
Residue from same	—	—	—	18
Cadder coking coal	10.40	32.97	50.44	16.19
Dried smokeless fuel from same	—	4.77	86.71	8.52
Greenhill coal	12.69	33.09	50.63	3.85
Dried smokeless fuel from same	—	3.9	—	—
Coke from horizontal re- torts	—	4.30	86.40	9.30

a horizontal retort. I would specially draw attention to the small quantity of volatile matter left in this coke. In one test it is actually less than in the gas works coke. I had always assumed that a low-temperature coke contained a considerable percentage of volatile matter, but in the present instances this is far from being the case. The low percentage of volatile matter might lead one to expect that the coke was as difficult to kindle as the ordinary gas works coke, but trial shows it to be quite easily kindled, certainly quite as readily as coal. Mr. Peter Fyfe, Secretary of the Coal Smoke Abatement Society, had a sample tested against ordinary coal and found that the coke fire kindled more quickly, and attained full redness in 45 minutes, while the coal fire took 1½ hrs. to attain to an equal redness.

The coal fire had to be re-charged in two hours, while the coke fire did not require to be replenished before 4 hours had elapsed. The temperature in the room with the coke fire was higher by two degrees than the temperature of the room with the coal fire.

Heat necessary for carbonising.

To ascertain how much hot gas would be required to carbonise satisfactorily one ton of coal, 13 tons of coal was treated, yielding an average of 13,725 cub. ft. of gas per ton; all the coke coming out during the run, which was of 22 hours' duration, seemed satisfactorily carbonised. Assuming 5000 cub. ft. of rich gas (700 to 800 B.Th.U.) to be given off from each ton of coal in compartment A, this meant a make of about 9000 cub. ft. of producer gas in compartment B, and as this gas, presumably, had a value of about 130 B.Th.U., the calorific value of the mixed gas should have been 351 B.Th.U. The average value found by calorimeter was 180 B.Th.U., and by gas analysis on one sample 206 B.Th.U. The small quantity of hot gas necessary to carbonise the fuel was very gratifying, but the low calorific value was both disappointing and inexplicable. According to published figures, by the late Prof. Lewes, with distillation at 400° C. one ton of coal would yield the products shown in column 1. Column 2 shows what were obtained at Port Dundas. Column 3 shows gas works results with high temperature carbonisation.

	Carbonising at 400° C.	Port Dundas method.	Gas works practice.
	Cub. ft.	Cub. ft.	Cub. ft.
C ₂ H ₂ , etc.	315	53	317

CO+CO ₂	620	2973	1200
N ₂	50	6294	100

In this trial therefore we obtained one-sixth of the olefines obtained by low temperature and high temperature distillation, and less than half the volume of methane. Unfortunately at this stage accurate measurements of the oil were impossible, owing to the difficulty of separating oil from water, but the percentage of light oil was ascertainable.

The following were the figures, supplied me through the kindness of the Gas Department, for the portion of the oil condensing in the first scrubber: Sp. gr. of water-free oil, 1.037. Distilling at 170° C. 0.34%, sp. gr. 0.968; 170° to 270° C. = 21.26%, sp. gr. 0.970; 270° to 425° C. 15.11%, 0.995; residue (solid), 62.30%, sp. gr. 1.085; loss, 0.69%.

The crude naphtha from low temperature tars is given by Lewis T. Wright as equal to 9% on the tar, or 9 lb. per ton of coal. With a high temperature it falls to 3.45% or about 3½ lb. per ton. In the Port Dundas results it falls to about ½ lb. per ton of coal.

In a second test run the gas was no better. The quantity of oil obtained, however, amounted to about 16 gallons per ton of dry coal. This time the distillate up to 170° C. gave 2.6% of naphtha of sp. gr. 0.965.

A third test was made in March of last year, using water gas, made by decomposing steam in compartment B, for effecting the carbonisation of the fuel. Naturally, this gave a better gas, owing to the comparative freedom from nitrogen, but the percentage of olefines varied from 0.2 to 1.1% and the methane from 7% to 13%, and the gas was therefore in this respect little better than formerly.

To ascertain whether light oils, if produced, could pass the scrubbers, gasoline of sp. gr. 0.650 was added both before and after the first scrubber at the rate of ½ gall. per 1000 cub. ft. The improvement in the gas at the gasometer was not apparent, and analysis showed the olefines and the methane to be practically unchanged. In the first test the olefines amounted to 0.2%, in the second to 1.1%—practically the same as the preceding two tests when no gasoline was used. The completeness with which the scrubbers were removing the gasoline might have misled, but fortunately the next test saved an erroneous impression. The scrubbers are centrifugal brush scrubbers, designed for cheapness. Each scrubber is 10 ft. × 4 ft. In order to keep conditions as uniform as possible, during the additions of the gasoline, the fuel was not disturbed in either A or B compartment, but as soon as the tests were over, ash was removed in compartment B, and an immediate improvement in the composition of

temperature method; though I firmly believe that illuminating gas will yet be made in a plant such as I have described. This, however, will be done by a semi-high temperature method.

At the completion of the third trial, in an endeavour to account for the absence of the light hydrocarbons, the oils were examined more thoroughly. The oil was so hopelessly mixed up with the ammonia liquor that it seemed impossible to get it into a marketable state. Even a sample which to all appearance was water-free, showed about 20% of water on distillation.

In the examination of these oils the Corporation allowed me to have the assistance of Mr. Harris, head of the Chemical Department, when required. Mr. Harris appointed Mr. Cockburn to assist in the investigation, and I have here to thank both gentlemen for their assistance and suggestions. The Gas Department also carried through analyses and distillations for me, and to them I am also indebted. The fickle character of the oil under distillation appears to be wholly responsible for the fact that a distillation carried out by the Chemical Department had no resemblance to a distillation of the same oil by the Gas Department. For instance, when Mr. Cockburn distilled a certain portion of the oil in a glass retort he got a series of fractions of steadily increasing viscosity. When the Gas Department distilled a larger quantity in a copper still, perfectly liquid oils came over to the end.

Oil.

The oils obtained from cannel coals were distinctly lighter than water, brownish green in colour, buttery in consistency. The setting point was about 30° C., they were apparently paraffinoid in character, and resembled the crude oil obtained from shale rather than that from coal tars. The oils from coking coals were decidedly heavier than water, darker in colour, about the consistency of butter; having a setting point about 20° C. and in general less paraffinoid in character than the oils from cannel. Both oils retain a considerable percentage of water with great tenacity. Typical distillation tests of some of the crude oils obtained are given below with water deducted.

Oil from cannel. Sp. gr. about 0.950.		Oil from coking coal distilled from copper retort.		Coking coal. Oil distilled from iron retort. Sp. gr. 1.048.	
	%		Sp. gr.		%
Oil of 0.819 sp. gr.	13.0	Oil to 170° C.	0.965	Oil to 170° C.	6.95
Oil of 0.850 sp. gr.	13.0	170° to 270° C.	0.968	170° to 230° C.	13.06
Oil of 0.910 sp. gr.	32.75	270° to 425° C.	0.992	230° upwards	46.64

(without freezing)					
Hard pitch	6.75				
Loss on washing, etc.	27.25				
	100.00		100		100.00

the gas followed. The olefines rose to 1.4%, the methane to 15.7%, and the calorific value to 377 B.Th.U. This improvement in the gas followed the bringing down of new fuel in B compartment, and the rise in the olefines was undoubtedly due to the hydrocarbons driven off from this fuel being partly decomposed, as they passed up through the hot fuel in compartment A, into ethylene and other light hydrocarbons. The scrubber allowed these light gaseous hydrocarbons to pass, while it prevented the passage of the heavier hydrocarbons of the gasoline.

These results, together with later results and numerous unrecorded results, convinced me that it was hopeless to look for rich gas by a true low

The high percentage of water made these oils troublesome to distil. The large percentage of pitch from the coking coals at the low prices prevailing, the want of knowledge of the nature and use of the distillates, made distillation unpromising. The prospect of using the oil direct for creosoting seemed more hopeful. On testing for phenolic substances, by extracting with caustic soda, 40 to 50% of the oil passed into apparent solution. With the high prices prevailing for carbolic and cresylic acids, it seemed unreasonable to offer this oil even at 3d. per gallon, the price of creosote oil, and I extracted a portion of the oil with caustic soda, separated the supposed phenols with sulphuric acid, and sent a sample of this

to the makers of Iysol, but they reported that it was useless to them.

Low temperature carbonisation has been repeatedly credited with a heavy yield of cresylic acid, and I considered that in this material there was probably a group of phenols of high boiling point. Phenol itself was not present in any quantity, since only very occasionally could its presence be traced by its action on the skin. The boiling point might have been a true indication as to whether the crude oils contained much cresol, but I found that decomposition apparently set in at about 200° C., so I assumed that we had to deal with phenolic bodies in combination with organic bases.

Crude oil and resinous portion.

Distillation appearing unsatisfactory, direct uses were sought for the crude oil. The fact that it dried on wood, leaving a glossy surface, when well rubbed in, suggested its use as a furniture polish or as a protective covering for wood. Wood rubbed with crude oil will afterwards take both paint and varnish. This, I am told, is not the case with coal tar oils, unless specially prepared.

The separated cresylic portion (see diagram), when heated at slightly over 200° C. for a short time, gives off phenolic vapours. Fully two-thirds will not come over at this temperature, but remains behind as a resinous pitch.

At this stage it was found that when the oil was agitated with paraffin in a separator, the mixed liquids divided into three layers, the top being a semi-liquid oil, the middle one water, and the lowest layer a heavy black resinous tar. If weak acid is added to the top oil, and it is again agitated, a second separation takes place, almost exactly similar to the first, only the bottom layer is redder in colour. This I have termed red resin. If the top oil of this second treatment be now treated with caustic soda, a portion passes into solution, and this can be separated with acid. For want of a better name I have termed it the cresylic portion. The neutral oil that remains after washing with water, I term Port Dundas lubricating oil. The diagram, Fig. 2, will help to visualise the separation, and the approximate quantities.

FIG. 2.

The resins, when thinned with turpentine, give satisfactory yellow varnish stains; with methylated spirit brown stains, and with benzol, black varnishes.

Distillation of the separated portions of the oil seemed to promise to give useful information, so we had the resin distilled. The result of dis-

tillation in a glass retort obtained by Mr. Harris's Department, is given below:—

C. D. Resin.

	%	
Water	3.3	
Oil to 150° C.	0.9	Dark brown fluid.
150°—185° C.	1.1	Yellow fluid.
185°—195° C.	1.3	
195°—215° C.	18.2	Golden brown } More viscid than above
215°—240° C.	2.6	Golden brown } Viscid.
240°—270° C.	3.5	Brown. } Very viscid.
270°—300° C.	7.5	Brown. } Thick jelly.
300°—320° C.	7.1	Dark brown. } Solid jelly.
320°—350° C.	7.1	Dark brown. } Solid jelly.
350°—355° C.	8.8	Almost black solid jelly.
	61.4	
Residue	38.6	
	100.0	

The temperature remained fairly constant at 200° C., and decomposition apparently set in at 355° C. The residue was a blackish, very friable pitch. Guaiacol and creosol were found to be absent, as was also abietic acid.

With the object of getting larger quantities of each fraction for refractionation, Mr. Macdonald, at Tradeston Gas Works, distilled a larger quantity in a copper still. The results of this are noted below.

C. D. Resin.

	%	Sp. gr.
Water	5.9	—
Oil up to 170° C. ..	3.35	0.907
170°—200° C.	1.55	0.962
200°—215° C.	4.65	0.974
215°—240° C.	5.80	0.980
240°—270° C.	6.00	0.982
270°—300° C.	8.30	0.986
300°—325° C.	3.60	0.991
325°—350° C.	0.20	
350°—370° C.	0.50	
	39.85	
Pitch	60.15	Sp. gr. 1.14; very hard and brittle.
	100.00	

All products were quite fluid, but dark in colour, and had an odour like that of solvent naphtha.

The difference in these results made it appear that distillation would be useless unless under reduced pressure or in a current of steam.

Lubricating oil.

A distillation of the lubricating portion of the oil, made by Mr. Cockburn, is given below. Up to 170° C. water=3.4%; oil=2.6%; 170° to 200° C.=1.0%; 200° to 270° C.=16.2%; 270° to 360° C.=34.0%; 360° to 370° C.=9.2%; 370° to 375° C.=4.4%; 275° to 310° C.=5.6%. The small percentage distilling over below 170° C. and the smell indicated the absence of benzene, toluene, etc., and of all the lighter paraffins, olefines, and naphthenes. The respective members of the three groups boiling about 200° C. are dodecane, $C_{12}H_{26}$; dodecene, $C_{12}H_{24}$; and dodecanaphthene, $C_{12}H_{18}$. Towards the end of the distillation crystals formed in the distillate, particularly between 290° and 360° C. These were apparently higher paraffins, but might be olefines or naphthenes. The drop in temperature, at 375° C. is particularly noteworthy. Mr. Cockburn remarks that "at this point (*i.e.*, 375° C.) the character of the distillate changed—a reddish oil coming over. The temperature fell steadily till it registered only 310° C. All the time, however, the reddish oil continued coming over, and a strong smell of ammonia was noticed (and detected by litmus). This reddish distillate measured 5.6%. Granular crystals separated on cooling—mostly naphthalene (judging by the picrate test). Decomposition of nitrogen compounds explains the presence of the ammonia."

This oil impressed me from the beginning as having remarkable lubricating qualities, and

although Lunge states that oils from blast-furnace tars made only inferior lubricants. I had the Port Dundas oil tested by the kindness of Dr. Gray in the Thurston friction machine. The first tests were very encouraging, and later tests have confirmed the remarkable lubricating power of these oils. I selected the best oils given by Hurst, for durability, and compared them with the Port Dundas oil, run under similar conditions. The results are shown on the following diagrams.

Fig. 3 gives the results with castor oil, sperm oil, and a heavy Port Dundas lubricating oil. With the castor oil the friction was so great that

FIG. 3.

the test was not proceeded with. The Port Dundas oil ran for 60 minutes the first day, and 25 minutes the second day. The pure sperm ran for 15 minutes the first day, and 50 minutes the second day. It is remarkable that the Port Dundas oil has always run at a lower temperature the second day, while most of the other oils tried have been slightly higher.

Fig. 4 shows a Scotch mineral oil of sp. gr. 0.890 run against a light Port Dundas oil for friction and durability only. This oil was the distillate between 290° and 340° C. of the lubricating portion of the oil. On filtering out the crystals, which were large, flat, waxy crystals, like paraffin, the durability of this oil decreased. The crystals smeared on the bearing improved the results again.

All the tests were run at 48 lb. pressure to the square inch on the bearing, and at 2000 r.p.m. Neither of these two oils indicated any tendency to gum.

The remarkable feature in the Port Dundas oil is the high durability shown, combined with the fact that its viscosity is very low; also the complete absence of any tendency to gum in a coal tar oil, which had not been distilled, and from which resinous substances had only been extracted by treatment with soda.

Dye products.

About this time it was found that water which had been standing over the resin, became strongly coloured red on addition of caustic soda. It was therefore of interest to examine the effect of alkalis on the resin; 3½ gallons was agitated with dilute sodium carbonate solution, the red liquor poured off, and the process repeated until 8 gallons of strong red liquor had been obtained. This occupied a week. The liquor after this became browner and muddier, and the extraction was stopped. Evidently if water extracted this colouring matter from the oil, the ammonia liquor which had been so thoroughly mixed with the oil should contain the same material. On adding caustic soda to the slightly acid ammoniacal liquor from the tanks, a bright blue colour was produced at once; a little more soda turned this red. The purple ammoniacal liquor was found to dye wool neutral grey shades. The red liquor does not dye unmordanted wool, but the colour is fixed

satisfactorily on a chrome mordant. When the purple colour was oxidised with bleaching powder, a dull yellow was obtained, which also dyed unmordanted wool.

The Port Dundas ammoniacal liquor is apparently free from both ferrocyanides and thiocyanates. The purple grey colouring matter can be obtained in a solid form by evaporation of the neutral liquor. The quantity present is quite considerable, and without any purification whatsoever, the ammoniacal liquor produces pleasing purple grey shades, which are at least faster to light than those obtained with the ordinary aniline dyes.

With the object of separating basic substances from the resin remaining after the soda treatment, it was treated repeatedly with dilute sulphuric acid, air being blown through the solution meanwhile. The solutions were coloured yellow, and on cooling deposited a golden-yellow resin very soluble in caustic soda and in alcohol, but insoluble in dilute acids. At the end of the third day's treatment the quantity of resin remaining amounted to about 4% of the oil originally used. It was still black, and on further treatment dissolved in the same manner as before.

The dilute yellow solutions thus obtained were found to dye wool, at the boil, without mordant, in shades fairly fast to washing. When the solutions were evaporated a dirty, unpossessing powder was obtained. This had very little dyeing power. When the resin itself was treated with nitric acid of a certain concentration a decided action ensued, and a yellow liquid was obtained, together with a light, spongy char. The yellow liquid was neutralised with lime, filtered, and evaporated to dryness. Attempts to purify this further resulted in the colour steadily disappearing. A rough calculation indicated that one ton of coal would have yielded sufficient resin to give by sulphuric acid treatment sufficient colour to dye 800 lb. of wool, but the yellow liquor obtained from the nitric acid solution would only dye a minute fraction of this. For some time I could not account for the disappearance of the yellow dye, until I found that the "char" from the nitric acid treatment, on addition of caustic soda solution, immediately gave rise to a solution so strongly coloured as to indicate that this char is practically solid yellow dye. On heating, this char softens like a resin. I am unable to give any enlighten-

FIG. 4.

ment as to the chemical nature of this product. It does not appear to contain nitrogen. By treating with sodium nitrite, chocolate and neutral browns are obtained, and these seem fairly fast to washing and to light.

All the shades produced by these products are much faster than picric acid and Methyl Violet dyeings; the least fast faded to about the same extent as Patent Blue, which is one of the faster of the triphenylmethane dyes. The dark grey blues on chrome mordanted wool, and some of the neutral browns have only been slightly affected.

The weak acid solution from a cannel coal,

contains a pale primrose colouring matter. The "cresylic portion" from a cannel contains no cresylic acid, but gives a red brown precipitate which by treatment with weak nitric acid gives two portions, a resinous scale and an iron-red precipitate. Both portions give with caustic soda raw sienna colouring matters, of considerable purity. These soda-soluble substances would suggest a phenolic or naphtholic origin, but the black resin, after boiling with caustic soda until the soda takes up no further colour and then treating with weak nitric acid, gives an almost similar colouring matter, in great quantity. I calculate now that one ton of coal will yield sufficient colour to dye 1500 lb. of wool.

I must mention, however, that the action of soda on the tars has been most erratic. A percentage equal to the black resins is extracted from the crude oil by caustic soda, while the black resin, precipitated by acid, is only very partially soluble in soda. The portion of this resin distilling over between 170° and 240° C. when treated with weak nitric acid also gives a yellow resinous colouring matter in large quantity.

I have already remarked that the crude oil dries quickly in air, and much more rapidly by the addition of a drier, such as manganese dioxide, in this respect behaving somewhat like a boiled oil. After agitating the oil in a closed separator with caustic soda, I have frequently noticed the inrush of air, on removing the stopper.

Before leaving the subject of dyes I must express my indebtedness to Mr. Steven and Dr. Gray for their help in the matter.

Ammonia.

The titration of the ammonia liquor does not require the addition of an indicator. In practice the change from a yellow colour to a purple colour indicated the time for the addition of more acid. The liquor was generally kept slightly acid (about 0.5% free sulphuric acid). If the rate at which the coal was being gasified was known, the time taken to neutralise a carboy of acid of known strength gave a measure of the free ammonia being produced, and this could be told directly by the appearance of the purple colour. My anticipation of 45 lb. per ton was based largely on the results obtained by Beilby in 1883, who found that when coal was exposed for several hours to a gas containing hydrogen at a moderate red heat, from 60 to 70% of the nitrogen of the fuel was obtained as ammonia. To keep down the temperature, both Beilby and Mond adopted the expedient of increasing the quantity of steam. Now steam is costly, and it has to be condensed out, and this involves large plant; I therefore decided to obtain the time of contact with the fuel, at an ammonia-yielding temperature, by ensuring that the fuel would not reach the combustion zone until it had been exposed for many hours to the hot gases at temperatures varying from 450° to 750° C. This only necessitated providing a large storage chamber surrounded by thick non-conducting walls. In Fig. 1 the zone, N, is the ammonia-producing zone, and as the coal takes approximately 20 hours to be heated from 15° C. to 1000° C. it will take about one hour for every 50° increase, and therefore an increase of 300° will occupy about 6 hours. By the time it reaches 750° C. I consider it has been sufficiently stripped of its nitrogen to make any further loss negligible.

The ammonia results are, unfortunately, for a variety of reasons, perhaps the least accurate; this side of the problem has not yet received the amount of attention which its importance merits.

My first experiments were with a cannel coal from Ayrshire. This gave approximately 40 lb. of sulphate of ammonia per ton. The next coal tested was also a cannel, this time from Lanark-

shire, and this, by determining the time to neutralise a carboy of acid, showed 63 lb. to the ton. The next tests were on Cadder coking coal, while running for smokeless fuel. As the oil and liquor could not be separated, no actual estimate was taken, but tests of the ammonia in the gas gave very low results. The coke in this case had very often a highly-glazed surface skin and probably did not allow of free access of the combustion gases to its centre.

The results with Greenhill coal, working for power gas, were better, one result showing 36 lb., and the one following 19 lb. as measured by the acid neutralised. In steady running these yields are likely to be exceeded, as on beginning the experimental test showing 36 lb., the fuel in the producer, at the start, had been much more completely denuded of its nitrogen than the fuel remaining in the producer at the end of the test. The cooling and scrubbing plant consisted of the two scrubbers already referred to, and as acid only passed through the first scrubber any ammonia passing to the second scrubber was entirely omitted. The amount of ammonia escaping would not be very great, our experience being that so long as the rate of gas passage did not exceed 50,000 cub. ft. per hour, little ammonia was carried forward.

Regarding the commercial side of the process, it is impossible to speak definitely until the market value of the oil products has been ascertained, but 2d. per gallon for the crude oil should make it worth considering in most situations.

The capital cost before the war of a plant capable of handling 20 tons of coal per day amounted to about £1000, exclusive of coal crushers, elevators, and driving engine.

The yields of all the products have been equal to my anticipations for the coals concerned, except illuminating gas, which has been a complete disappointment, though the enhanced value of the oils may be found to more than counterbalance this.

Approximate yields for the kinds of coal handled are given below.

Working for smokeless fuel. Gas, 10,000 cub. ft. per ton. 330 B.Th.U. Oil, 16 galls. (7%). Liquor, 12%. Smokeless fuel (5% volatile), 65%.

Coking coal. Gas, 141,000 cub. ft. per ton. 112 B.Th.U. Oil, 16 galls.; sulphate of ammonia, 45 lb. Energy loss, 6,250,000 B.Th.U. per ton.

Cannel coal. Gas, 80,000 cub. ft., 114 B.Th.U. Oil, 32 galls. Sulphate of ammonia, 36 lb. Energy loss, 4,750,000 B.Th.U. per ton.

The energy losses will probably be reduced as experience grows. The low capital cost of the plant is largely due to the gases leaving the producer comparatively cool, hence reducing the condensing power to a minimum.

The small amount of steam necessary makes a great saving in working costs and condensing plant.

The most interesting results from the chemical side are:—

- (1) The small quantity of hot gas required to carbonise a ton of coal.
- (2) The small percentage of light olefines present in the gas.
- (3) The relative absence of light portions—benzene homologues, carbolic and cresylic acids—in the crude oil.
- (4) The presence of resinous substances in the oil.
- (5) The lubricating quality of the non-resinous oil.
- (6) The drying properties of the crude oil.
- (7) The presence of dyes in the ammonia liquor and the oil.

Further investigation of these various products is likely to prove fruitful commercially, and highly interesting.

In conclusion, the author desires to express his thanks to those who have assisted him, especially to the Corporation of Glasgow, and to Mr. Hardie, upon whom a great deal of the work has devolved.

MR. A. R. LING IN THE CHAIR.

THE RATE OF REVERSION OF MIXTURES OF SUPERPHOSPHATE WITH BASIC SLAG AND ROCK PHOSPHATES.

BY G. SCOTT ROBERTSON, M.Sc.

During the past winter considerable difficulty has been experienced by British farmers in obtaining superphosphate. Up to the present the shortage in the supply of this important fertiliser has been due chiefly to the unlimited demand made by the Ministry of Munitions for sulphuric acid. It was highly desirable, therefore, to ascertain the best method of eking out the limited supply of superphosphate. With this object in view, and at the suggestion of the Board of Agriculture, the experiments recorded in this paper were undertaken. Just as the investigation was completed the Board was informed that the available supply of sulphuric acid was in excess of the supply of rock phosphate. Although, therefore, the investigation loses its immediate importance, yet certain of the results are capable of practical application. Furthermore, it is possible that the British farmer may experience similar difficulties during the coming winter.

If suitable mixtures of superphosphate with insoluble phosphates can be obtained, the superphosphate will be distributed over a much larger area, and the aggregate return will be much greater, than if the superphosphate were applied to a limited area at the usual rate of 2-6 cwt. per acre.

Basic slag of low and high citric solubility, and rock phosphates are the two chief sources of insoluble phosphate, and of each the available supply is far beyond our present requirements.

It is, therefore, a matter of importance to determine the extent of the changes which take place when the above-mentioned insoluble phosphates are mixed with superphosphate.

Basic slag and superphosphate mixture.

This mixture consisted of $\frac{1}{2}$ cwt. 26% water-soluble superphosphate and $\frac{1}{2}$ cwt. 26% citric-soluble basic slag (Albert's). The slag and superphosphate were thoroughly mixed together, passed through a riddle, sampled, and the water-soluble and citric-soluble phosphate determined at once. During mixing the mixture became exceedingly hot, and by the time it was ready for putting into the bag it was as hot as the hand could comfortably bear. The bag was removed from the mixing shed and stored in the laboratory. There was a marked tendency on the part of the mixture to form small but rather hard lumps.

The analysis of the slag and superphosphate used is given in Table I. By calculating from these analyses, the mixture at the moment of mixing had the following composition:—

Water-soluble phosphate ($\text{Ca}_3\text{P}_2\text{O}_8$)	12.99
Citric-soluble " "	26.38
Total phosphate ($\text{Ca}_3\text{P}_2\text{O}_8$)	28.18
Citric solubility of the phosphate	93.6

The mixture was sampled several times in the course of four months. On each occasion it was spread on the laboratory floor and turned over

at least three times before the sample was withdrawn. The sample was quickly and gently ground by means of a mortar and pestle and the water-soluble and citric-soluble phosphate determined immediately. The results are given in Table II.

Reversion of the water-soluble phosphate to the water-insoluble form takes place at a very rapid rate. About 80% of the water-soluble phosphate in the mixture reverts to the water-insoluble form

TABLE I.

	Gafsa rock phosphate. Basic slag.	Super-phosphate
	%	%
Water-soluble phosphoric acid (P_2O_5)	—	11.90
Water-soluble phosphate ($\text{Ca}_3\text{P}_2\text{O}_8$)	—	25.98
Citric-soluble phosphoric acid (P_2O_5)	9.78	12.53
Citric-soluble phosphate ($\text{Ca}_3\text{P}_2\text{O}_8$)	21.35	27.35
Citric soluble lime	17.44	14.28
Total lime, CaO	42.50	29.20
*Carbon dioxide (CO_2)	5.34	—
Free caustic lime (CaO) by sugar solution	—	1.60
Silica (sand)	8.21	15.90
Total phosphoric acid	25.10	13.28
Total phosphate ($\text{Ca}_3\text{P}_2\text{O}_8$)	54.79	28.99
• Equivalent as calcium carbonate	12.14	0.21
Lime as uncombined calcium carbonate	0.72	—
Citric solubility of the phosphate	39.0	91.3

within 24 hours; 60% of the water-soluble phosphate reverts before portions can be withdrawn for analysis, that is to say within half an hour. It seems clear also that reversion practically ceases before the mixture is four days old.

The basic slag used in the mixture contained 47.75% of calcium oxide (lime), 23.89% of available lime,* including 1.69% of free or caustic lime, and 0.12% of lime (CaO) as calcium carbonate. The amount of available lime present in the mixture is more than five times the amount required to revert the whole of the water-soluble phosphoric acid to the water-insoluble form. It is clear, therefore, that the extent of the reversion of the water-soluble phosphate in any such mixture is directly proportional to the amount of caustic lime and calcium carbonate which the mixture contains.

The amount of caustic lime and calcium carbonate in basic slag is much less than is generally assumed, but in the slags which the writer has examined it is seldom much less than 2% of lime (CaO).

The percentage of citric-soluble phosphate in the mixture is very close to the calculated amount. Just after mixing there seems to be a slight decrease in citric solubility, followed by a gradual recovery on keeping, but the differences are so small as to be negligible and are certainly without any practical significance.

On the whole it cannot be said that a superphosphate and basic slag mixture has anything particular in its favour. If the basis of the mixture is one half 26% superphosphate and one half basic slag, it is clear that if the slag contains 2% of caustic lime practically all the water-soluble phosphate in the mixture will revert in a few hours. The mechanical condition is not improved by

* The term "available lime" means the excess of citric-soluble lime over that required to combine with the citric-soluble phosphoric acid to form tricalcium phosphate, $\text{Ca}_3\text{P}_2\text{O}_8$. In basic slag the greater part of the so-called "available lime" is, together with silica, combined with the calcium phosphate, and only a small amount, often not more than 2%, is in the form of caustic lime or calcium carbonate.

phosphate, but it should be borne in mind when comparing these results that the residual value of the Tunisian rock phosphate will be felt to a far greater extent on the succeeding crops than the superphosphate.

The experiments conducted by Professor Gilchrist at Cockle Park also demonstrate in a striking manner the efficiency of a mixture of superphosphate and rock phosphate for a three years' ley.*

In the Journal of the Irish Department of Agriculture, referred to above, the opinion is expressed that on no account should the 2 to 1 mixture be purchased without a guarantee that the mineral phosphate contained therein is of "North African origin," and the results which follow lead to the assumption that Tunisian phosphate is the most suitable for mixing with superphosphate.

This opinion is certainly open to criticism. The comparative absence of uncombined calcium carbonate, and the availability of the phosphoric acid, in the rock phosphate are far more important points in deciding the suitability for mixing with superphosphate than the question of origin. North African phosphates are not always free from excessive amounts of uncombined calcium carbonate; indeed Tunisian phosphate is very liable to contain large quantities of uncombined calcium carbonate—varying in the author's experience from 2 to 12% of calcium oxide. The larger the amount of uncombined calcium carbonate present, the greater will be the reversion of water-soluble phosphate to the insoluble form when mixed with superphosphate.

Gafsa rock phosphate (a North African phosphate) is probably the most suitable for mixing purposes, as it very rarely contains more than 0.75% of calcium oxide in the form of free carbonate. This phosphate has the additional but doubtful advantage of being more soluble in 2% citric acid than any of the other rock phosphates. Egyptian phosphate is probably the next best for mixing purposes, and then come Florida pebble phosphate, and Makatea Island phosphate, followed by Tunisian and Algerian phosphates.

If Gafsa phosphate containing at least 26% of phosphoric acid is used for mixing with superphosphate, the reversion of water-soluble phosphate will be small. But if low grade varieties of rock phosphates, containing 25% and under of phosphoric acid, are used, the reversion of the water-soluble phosphate to the water-insoluble form in the superphosphate mixture will be considerable.

Superphosphate and rock phosphate produce a very nice mixture, particularly if the superphosphate is in a friable condition.

Mixtures of rock phosphate and superphosphate might be rendered even more efficient if the rock phosphate was ground a great deal finer than it is. As a rule rock phosphate for the making of superphosphate is not ground quite so finely as basic slag. From 70 to 80% only passes a sieve with 10,000 holes to the square inch, whereas basic slag has a corresponding fineness of from 80 to 90%. It is perfectly feasible to have the rock phosphates ground so that upwards of 80% will pass a sieve with 40,000 holes to the square inch, and there is every reason to suppose that by so doing the efficiency of the mixture with superphosphate would be greatly improved.

The author wishes to acknowledge his indebtedness to Mr. J. G. Stewart, M.A., of the Board of Agriculture and Fisheries, and to Mr. R. M. Wilson, B.Sc., Principal of the East Anglian Institute of Agriculture, at whose suggestion this investigation was undertaken.

MR. J. H. HOSEASON IN THE CHAIR.

THE EXAMINATION OF ACETIC ANHYDRIDE.

BY L. G. RADCLIFFE, M.Sc. TECH., AND
S. MEDOFSKI, B.Sc. TECH.

Acetic anhydride is, unfortunately, of rather variable composition owing to the lack of care given to its purification. Its technical value depends very largely on the percentage of real anhydride which it contains or, in other words, on its freedom from acetic acid. The examination of acetic anhydride must include the detection of impurities resulting from the process used in its manufacture. In the Feb. 28th, 1916, issue of this Journal (pages 210—213) will be found an excellent review, by J. T. Hewitt and C. H. Lumsden, of the methods used for preparing acetic anhydride, in which is also included an account of methods for the detection of such impurities as phosphorus, chlorine, and sulphur.

Commercial acetic anhydride usually contains from 70 to 90% of real anhydride, and the percentage of anhydride can readily be increased to 97% or more by careful fractional distillation with a suitable still-head (*vide* Orton and Jones, Chem. Soc. Trans., 1912, 101, 1721; this J., 1912, 898). In one experiment the amount was increased from 85% to 91% anhydride by one fractional distillation.

The authors have made a comparative study of the published methods for determining the percentage of actual anhydride in commercial acetic anhydride, and the methods and results are given below. Much of the acetic anhydride now available is yellow in colour and this coloration is difficult to remove by simple distillation, but if the acetic anhydride is distilled off from a little phosphorus pentoxide the resulting product is colourless. This treatment has no effect in raising the percentage of anhydride, indeed, it appears to decompose the substance slightly as the pentoxide blackens and the residue after distillation is viscid and almost black; the percentage of anhydride after three treatments with phosphorus pentoxide and distillation is actually less than in the original sample. This points to a decomposition being effected by the phosphorus pentoxide. It was thought that the acetic acid might be removed from the acetic anhydride by shaking the latter quickly with a saturated solution of salt, then separating, drying over anhydrous sodium sulphate, filtering, and distilling, but again the percentage of anhydride was diminished from 85% to 73%.

Incidentally it was noticed that some of the sodium sulphate had dissolved in the mixture of acetic anhydride and acetic acid. The three distillations over phosphorus pentoxide reduced the percentage of anhydride from 85 to 77%.

The percentage of acetic anhydride in mixtures of anhydride with acetic acid cannot be determined by direct methods. The procedure generally adopted is:—

(A) *Treadwell's method* ("Analytical Chemistry," 1911, Vol. 2), in which a known quantity of the anhydride is treated with barium hydroxide solution and the excess of this titrated as described later. Another method, similar in principle, is to hydrolyse the anhydride with water and determine the amount of acetic acid formed.

(B) *Method of Menschutkin and Vasilieff* (J. Russ. Phys. Chem. Soc., 1889, 21, 190), in which

the anhydride is mixed with aniline, with which it forms acetanilide and acetic acid, the acidity being determined after the reaction. This method has been modified and described in the "Analysis of Crude Glycerine, International Standard Methods, 1911." The details of the methods as used by us are as follows:—

(A) *Direct titration.* Into a weighed stoppered bottle containing from 10 to 20 c.c. of water is run in about 2 grms. of the sample of acetic anhydride and the stopper replaced and the bottle again weighed. The mixture is allowed to stand, with occasional shaking, for several hours or it may be heated gently in a flask fitted with a reflux condenser, on a water-bath, until the acetic anhydride has been completely hydrolysed; this requires about twenty minutes. The acid is then titrated with *N*/1 caustic soda, using phenolphthalein as usual. If *p* is the weight of sample taken, and *q* the weight of acetic acid found from the number of c.c. of *N*/1 caustic soda used, then the weight of acetic anhydride present is $5.6641(q-p)$.

(B) *Barium hydroxide method of Treadwell.* About 1 gm. of the sample is weighed into a flask and mixed with a known volume, *i.e.*, an excess, of barium hydroxide solution, usually *N*/5 or *N*/10. The flask is attached to a small reflux condenser fitted with a soda-lime tube and the mixture heated on a water-bath until the anhydride is completely hydrolysed. The excess of barium hydroxide is then titrated with *N*/10 hydrochloric acid, using phenolphthalein as indicator. The equations for calculating the percentage of anhydride are the same as in the previous method (A).

Analysis of Crude Glycerine, 1911," and has been abstracted entirely therefrom.

Into a weighed stoppered vessel, containing 10–20 c.c. of water, is run about 2 c.c. of the anhydride, the stopper replaced and the vessel weighed and allowed to stand, with occasional shaking, for several hours till all anhydride is hydrolysed; the mixture is then diluted to about 200 c.c. with water, and titrated with *N*/1 caustic soda, in presence of phenolphthalein. This gives the total acidity due to free acetic acid and the acetic acid formed from the anhydride. Into a stoppered weighing bottle containing a known weight of recently distilled aniline (from 10–20 c.c.) is measured about 2 c.c. of the sample, the stopper is replaced, the contents mixed, allowed to cool, and the bottle weighed. The contents of the weighing bottle are washed into about 200 c.c. of cold water and the acidity titrated as before. This yields the acidity due to the original, preformed, acetic acid plus one-half the acid due to anhydride (the other half having formed acetanilide); the second result is subtracted from the first (both calculated for 100 grms.) and the result doubled, obtaining the c.c. of *N*/1 caustic soda per 100 grms. sample (1 c.c. of caustic soda = 0.0510 gm. anhydride).

(E) If the method of Menschutkin and Vasilieff be modified so as to use 20 c.c. of aniline instead of 2 or 3 c.c., then the heat generated by the reaction is absorbed by the excess of aniline and the secondary reaction does not take place. As will be seen in the table, the results obtained when using this modification agree with those given by the other methods.

(c) Fraction b.pt. 140°–146°	—	—	—	89.62	—	—	89.13	88.76
IV.—"Pure" acetic anhydride, colourless ..	1.0824	1.3851	135–138	92.48	94.35	109.23 108.73 109.56	92.72	93.1

(c) *Method of Menschutkin and Vasilieff.* Into a stoppered weighing bottle containing a known weight of aniline (2 to 3 c.c.) is run in about 2 grms. of the sample, the stopper replaced, and the contents shaken. Much heat is generated, and the mixture is allowed to cool and is weighed after which it is washed into a flask with alcohol and titrated with *N*/1 caustic soda, using phenolphthalein as indicator.

Treadwell has criticised this method, asserting that a secondary reaction takes place due to the great heat of the reaction between the acetic anhydride and the aniline, this causing the acetic acid produced to acetylate some of the aniline. He found that the percentages of anhydride obtained by this method were invariably from 14 to 16% too high. In several trials by this method, a sample of acetic anhydride, which according to the barium hydroxide method contained 94.3% of acetic anhydride, gave results indicating 109.23, 108.73, and 109.51% of acetic anhydride. Analyses of a sample of acetic anhydride which had been found to contain 85% of anhydride by the barium hydroxide method and also by the method described in detail below, were found to give figures from 98.42 to 98.76% of anhydride.

(D) The following method was given by the British Expert Committee's "Report on the

There is no doubt that, of the methods described, the direct titration is the shortest but the British Expert Committee's method is the safest in that it affords three ways of arriving at the percentage of acetic anhydride, *i.e.*, using the formula given in (A), the formula in (C), and the method given in (D).

In connection with the study of the behaviour of various strengths of acetic anhydride for acetylations, and also of the sulphur chloride method for its preparation, it became necessary to examine the anhydrous sodium acetate used. It has been stated that crystallised sodium acetate corresponds to the formula, $\text{CH}_3\text{COONa} \cdot 3\text{H}_2\text{O}$, and that on exposure to air the salt effloresces and loses the whole of the water of crystallisation. According to the experiments recorded below the latter statement is incorrect. Ordinary crystallised sodium acetate was treated in a platinum crucible with strong sulphuric acid and heated until the weight of the sodium sulphate residue remained constant; from this the percentage of sodium in the salt was calculated.

Calculated for $\text{CH}_3\text{COONa} \cdot 3\text{H}_2\text{O}$ —16.9% of Na.
Found, 16.85% Na.

Two weighed samples of this sodium acetate, one in crystals and the other in fine powder, were exposed on watch glasses for one week, to the air

of the laboratory, and weighed every day. No loss in weight occurred in either case, indeed a slight gain was noticed. These experiments dispose of the idea that crystallised sodium acetate loses its water of crystallisation on exposure to ordinary air. In a further experiment the weighed quantities of the sodium acetate were placed on watch glasses in an ordinary calcium chloride desiccator and weighed repeatedly during a period of 12 days; at the end of this time the weight remained constant and the loss corresponded exactly to the change of $\text{CH}_3\text{COONa} \cdot 3\text{H}_2\text{O}$ into the anhydrous CH_3COONa . Theoretical loss 39.7%, found 39.7%. The loss averaged about 1% per day, and was singularly regular.

A sample of the same crystallised sodium acetate lost, on careful fusion, 39.4%. A further trial was made heating the crystallised acetate in a steam oven, at 97° to 100° C., when the loss, in 12 hours, amounted to 39.8%.

From these experiments it is clear that crystallised sodium acetate can be completely dehydrated either by heating in a steam oven or by simply confining in a desiccator for a prolonged period.

Anhydrous sodium acetate is very hygroscopic and should be preserved in a desiccator. A sample of carefully fused and powdered sodium acetate exposed to the air at the ordinary temperature in the laboratory absorbed 65.5% of moisture in 32 days. Fused sodium acetate should absorb 65.8% of moisture if it regenerates the crystallised salt, $\text{CH}_3\text{COONa} \cdot 3\text{H}_2\text{O}$.

We desire to thank Mr. M. Barash for his assistance in some of the later experiments.

DISCUSSION.

Dr. J. J. Bloch asked whether acetic anhydride had been distilled over dry sodium acetate and if the yield of anhydride had been increased.

Mr. RADCLIFFE said the experiment had been tried but there was no appreciable increase in the strength of the anhydride.

Professor A. LAPWORTH mentioned that Kipping, some 20 years ago, had found that fatty acids yielded the corresponding ketones with phosphorus pentoxide, so that the formation of acetone would be expected in that case; dehydration of acetone with acetic anhydride would be very natural and consequently there would be a fall in the percentage of anhydride. There was a danger in generalising about losses of moisture from hydrated salts; he assumed that the experiments with sodium acetate had been made in Manchester; possibly if they had been carried out in Japan or other places where calcium chloride solutions are said to dry up in the open air, the sodium acetate might have lost its moisture.

Mr. RADCLIFFE agreed with Professor Lapworth with respect to the first point. He appreciated Professor Lapworth's remarks with regard to the loss of moisture; though under the conditions mentioned no loss took place, it was quite possible that dehydration might take place under suitable atmospheric conditions. A process was described by Hewitt, in which acetic anhydride was made in fairly large quantities by the action of sulphur chloride on anhydrous sodium acetate. In adopting this process it was essential that the sodium acetate should be thoroughly dry.

paid last year by the author to the United States. Industrial research is classified according to whether it is undertaken by manufacturing corporations, associations of manufacturers, universities and colleges, national institutions, commercial laboratories, or scientific societies. Typical examples are given of research laboratories connected with each of the above classes, and descriptions and illustrations of these laboratories are included.

The author points out that as yet little has been done to prevent overlapping of research and that there is at present no comprehensive scheme of research applying to industry in the United States as a whole. Reference is made to the appointment of the National Research Council, with the object of co-ordinating the scientific research work of the country. A movement has also been started by the Land Grant College Engineering Association, which has resulted in the promotion of a Bill having for its object the establishment in each State of a "Mechanic Arts Experiment Station" for conducting researches in connection with the production of "substances utilised in the application of mechanic arts to industrial pursuits." The Federal Government is asked to contribute £3000 per annum to each State for this purpose, and it is proposed that these experiment stations should co-operate with the existing Agricultural Experiment Stations.

The American Association for the Advancement of Science has appointed a committee, comprising some of the most prominent men connected with industrial research, with the object of securing more effective adaptation of research facilities in the various universities and experiment stations to industrial and national needs.

The U.S. Department of Agriculture and Bureau of Mines represent very complete organisations for dealing with their particular fields of research, and embody features which may serve as a basis for a national research scheme in other industries; particularly is this the case in regard to the means that have been developed for collecting and distributing data.

Discussing the organisation of British industrial research, the author urges that the higher forms of research should be carried out on national lines and should be organised in such a way as to link up the scientific resources of the Empire. An Imperial research organisation might not only result in the development of means for cheapening the production of raw materials, but might also assist in finding suitable outlets for the use of new materials discovered in the Overseas Dominions.

The following alternative schemes of research are suggested as possible in Great Britain: (a) Research laboratories in individual works. (b) Research laboratories for a group of works in the same industry. (c) The centralisation of research in the universities or colleges. (d) An Imperial centralised laboratory for the whole of industry. This centralised laboratory would result from the grouping together of the single laboratories dealing with the research requirements of each industry (b), and would be controlled by a board largely represented by manufacturers. It would possess many advantages; thus costs would be lower by adopting this form of co-operation, but the greatest advantages would accrue from the corporate life of such an institution and the interchange of views between the heads of the various sections. It is suggested that university staffs might take up research work from time to time in this laboratory, and so keep in close touch with modern progress. It is believed that the establishment of such a central institution would induce firms to instal their own laboratories, in co-operation with the central laboratory, for dealing with manufacturing troubles and problems connected with their own products.

Industrial Notes.

INDUSTRIAL RESEARCH IN THE UNITED STATES.

The Advisory Council for Scientific and Industrial Research has published, under the above title, the first of a series of papers bearing on industrial research. The present paper, by A. P. M. Fleming, has been prepared as a result of a visit

The author concludes by urging the necessity for better education and training of men for all grades of industrial employment, and also for bringing before the public the value of industrial research, with its possibilities and benefits, and so developing public opinion on desirable lines

DEVELOPMENT OF INDIAN FOREST PRODUCTS.

Lecturing before the Royal Society of Arts on April 19th, Mr. R. S. Pearson, F.L.S., Forest Economist at the Forest Research Institute, Dehra Dun, India, said that in 1906 the Government of India, at the instance of Sir Saint-Hill Eardley-Wilmot, the then Inspector-General of Forests, embarked on a scheme to encourage more intensive management in the forests and to further the development of forest industries. The scheme contemplated the erection of a Forest Research Institute, consisting of five branches, namely, Silviculture, Botany, Forest Economy, Chemistry, and Zoology. Later, the services of pulp and tan experts were made available. This Institute has lately been completed, and supplies a long-felt want.

Manufacture of matches.

The first enquiry of any magnitude undertaken was in connection with the match industry. Mr. R. S. Troup, the then Forest Economist, sent specimens of many species of timber to Europe to be tested, and, after inspecting various areas, selected factory sites near the source of supply of suitable timbers. He also collected information as to the supply of chemicals, studied the state of the markets, etc. Before this investigation was carried out a few match-factories existed in India, though they were at that time only in an experimental stage. Since then several new and much larger factories have come into existence, and the industry may now be considered to be established in that country. The solution to manufacturing matches of the first quality in India lies in the use of the Himalayan silver fir and spruce. The difficulty in the way of such a proposition is extraction, as these species occur at high altitudes in the Himalayas, while many of the trees are of great size. To overcome this, it is probable that mechanical means of extraction, such as wire ropeways or light tramways, will have to be adopted, combined with the erection of portable splint-making machines in or in the vicinity of the forests, whence the splints will be exported to central places in the plains, and there made up into matches.

Manufacture of paper pulp.

The manufacture of paper in India is not a new industry, it having been started by the erection of a mill near Bombay in 1862. At the present time there exist at least four large paper mills, which not only manufacture paper, but also part of their pulp requirements. Their gross out-turn was about 25,000 tons per annum in pre-war times, the output having somewhat increased since 1914. The imports of paper into India in 1914-15 amounted to 51,390 tons, valued at £709,372.

The most universally known raw material used for the manufacture of paper pulp in India is a grass known as "sabai" or "bhabar" (*Ischemum angustifolium*). Other raw materials used are waste jute, ropes, old gunny bags, and a limited amount of old paper and rags. The remainder of the pulp utilised for the manufacture of paper by the Indian mills consists of imported mechanical and sulphite spruce pulp, the imports of which in 1912-13 amounted to 13,250 tons.

Researches on bamboos by R. W. Sindall and W. Raitt, and on certain elephant grasses by Raitt

and R. S. Hole, carried out at the Forest Research Institute, have definitely established the value of these products as raw materials for paper manufacture. In the case of the bamboo, the investigation has resulted in leases being taken up in India and Burma for the manufacture of paper pulp; the war has, however, prevented much progress being made in the erection of factories. The investigation of the elephant grasses established the fact that certain of them, especially *Saccharum spontaneum*, *S. Narenga*, and *Phragmites Karka*, occurred in abundance and could be extracted cheaply, whilst the pulp prepared from the stems, especially of the former species, was of fair quality.

There is no doubt that both bamboos and certain elephant grasses may in the future play a prominent part in the paper-pulp industry of the world, as they present no great difficulties in extraction, while from their mode of growth and quick reproduction they have an enormous advantage over wood, which takes many years to come to maturity.

Antiseptic treatment of timbers.

In 1909 a series of experiments was carried out to ascertain the most suitable methods of treating various timbers for use as railway sleepers. The antiseptics used were coal-tar creosote and petroleum products, salts, and combinations of salts and oils. Generally speaking, the oils have given better results than the salts, which is as might be expected, as the salts are apt to be leached out of the timber by excessive moisture. Again, the lower boiling-point oils have not answered so well as those containing heavier fractions, as, for instance, green oil.

Later a more extensive series of tests was started, five species of timber being treated with four different antiseptics. In all, nearly 8000 sleepers have been treated, the timbers used being *Pinus longifolia* and *exelsis*, *Dipterocarpus tuberculatus* and *alatus*, and *Terminalia tomentosa*. The results to date are satisfactory, though the sleepers have not yet had time to demonstrate the true value of the treatment; still it may be noted that while *Pinus longifolia* lasts two and a half years at most in an untreated state, it has only been found necessary to remove two or three "Powellised" sleepers after five years, and those for mechanical and not physical defects. The other species are more durable than the above pine and last for four to five years in an untreated state, while *Terminalia tomentosa* may last up to eight or ten years in exceptional cases. All the above sleepers were treated in open tank with long immersion periods. Sleepers were also sent to England for treatment, both by the "full-cell" and "Rüping" processes, and afterwards returned to India and laid.

As an outcome of this movement to treat sleeper woods in India, three open-tank treating plants have been erected by the United Provinces Government, in which *Pinus longifolia* sleepers are treated in creosote and petroleum oil mixed in equal quantities. The State railways are also considering the erection of a pressure plant on the North-Western Railway. Other schemes for treating *Dipterocarp* sleepers from the Andamans and Assam are also under consideration and may be expected to mature after the war.

All creosote has to be imported and costs about 1s. 4d. per gallon at a treating centre in India, so that every effort has to be made to reduce the cost of the antiseptic. A good grade of creosote has recently been produced in India, but at a relatively high price, which, however, can no doubt be reduced. As soon as a good grade of coal-tar creosote is obtainable in India at a reasonable figure, it is anticipated that the antiseptic treatment of timber will advance by leaps and bounds, while a new industry will come into existence by the manufacture of creosote.

Rosin and turpentine industry.

An industry which was started many years ago on a modest scale was that of the production of turpentine and rosin from "drip," obtained from *Pinus longifolia*. In the last six years great developments have taken place in that industry: the United Provinces Government has erected a steam distillation plant at Bhowali, near Naini Tal, which is capable of handling about 3000 tons of crude rosin annually, while the Punjab Government has purchased an up-to-date French plant, of about 1000 tons capacity, which has been erected near Lahore. Improved methods of tapping have also been evolved. The result has been a heavy drop in American imports, and the commencement of a modest export trade. The industry is capable of still further development in the *Pinus longifolia* areas, and can probably be extended to Assam and Burma in connection with the "drip" obtained from *Pinus Khasya*.

Tannin extracts.

It is thought that there is a good opening for the preparation of tannin extracts from mangrove barks. Mangrove forests are found extending over large areas on the Aracan, Bassein, Tavoi, and Mergui coasts of Burma. The Government have recently appointed a tan expert from England, who is bringing out an up-to-date plant with which to experiment.

Boswellia serrata oleo-resin.

One of the most common trees in the dry zone forests of India is *Boswellia serrata*. It yields a valuable oleo-resin, and a simple means has been found by which it is possible to split it up into its component parts. Quite recently samples of the resin have been submitted for valuation to the Imperial Institute, which classed it as equal to "G" grade colophony, while one Calcutta firm has pronounced it excellent for varnish work, and another suitable for the preparation of shellac. Samples of turpentine have been pronounced to be of very good quality and closely resembling American turpentine oil, except as regards the smell.

Other industries.

Amongst other industries which it is hoped may be developed in the near future in India, are the introduction of more up-to-date methods of extracting "cutch" and "kuth" from *Acacia catechu*; the introduction of steam distillation instead of the present direct fire process for the extraction of "rosha" or "palmarosa" oil from *Cymbopogon Martini*, a grass found in Central India, the Central Provinces, and the Deccan; the more extensive cultivation of lac and improved methods of preparation; and the extraction of "kosum" oil for soap-making and the preparation of glycerin from the seeds of *Schleichera trijuga*.

Interim reports were received and approved on the necessity for an anthropological survey of the British people, on the best methods for carrying on the International Catalogue of Scientific Literature, and on an enquiry into the desirability or otherwise of the adoption of the metric system throughout the British Isles.

The Sub-Committee on National Instruction in Technical Optics reported that a scheme approved by the Board of Education had now come into operation. Under the aegis of the Imperial College of Science and Technology, an Advisory and Administrative Committee had been formed to organise instruction, and Mr. F. J. Cheshire, a member of the Sub-Committee of the Board, has been appointed Director of Studies in Technical Optics. Although the President of the Board of Education did not see his way to adopt the suggestions of the Sub-Committee, the Board heard with satisfaction that a promising effort has been made to solve a question of considerable national importance.

A Sub-Committee, having considered special cases of magnetic disturbances revealed by a magnetic survey of the British Isles and their possible connection with the occurrence of iron ores, recommended a detailed investigation of two test areas, in order of ascertain how far, under the conditions of the British iron ores, the magnetic survey was likely to prove of economic value. Arrangements for carrying out the investigation are in progress.

An Agricultural Sub-Committee, with the Earl of Portsmouth as Chairman, reported that it is at present devoting itself mainly to engineering questions. It is engaged in collecting information with regard to the transport of raw materials to farms and agricultural products from them, to the power required for this purpose, and for seasonal operations on the land, with a view to comparing the relative advantages and costs of steam or internal combustion engines and electrically operated machines. It is dealing also with the possibility of co-operation in repairs and skilled labour, and is considering the various types of tractor most suitable to large and chiefly arable farms and to moderate sized mixed farms, having regard to the different local circumstances and requirements.

A Sub-Committee was nominated to report on what is at present being done to ascertain the amount and distribution of water power in the British Empire.

PRESERVATION OF GLASS RECEPTACLES.

In view of the great scarcity of glass bottles, jars, etc., the Board of Trade draws attention to the desirability of not destroying any glass receptacles when emptied of their contents, but of returning them to the trade through bottle dealers or otherwise for use again. Arrangements have been made by the Confectionery and Preserved Food Manufacturers' Federation for the purchase for cash by meat-preserving firms of glasses issued by them, provided that they are in a usable condition. It is suggested that second-hand bottle dealers, having collected a quantity of such glasses, whether from private houses or shops, to the weight of not less than one ton, should communicate with the Secretary to the Federation, 9, Queen Street Place, London, E.C.4., with a view to their purchase through the Federation's collecting agency. Glasses so collected will be thoroughly cleansed before being used again, but in view of the importance of avoiding any danger to public health users should, wherever possible, wash any glasses in their possession before returning them.

CONJOINT BOARD OF SCIENTIFIC SOCIETIES.

The fourth meeting of the Conjoint Board of Scientific Societies was held at the Royal Society on June 13th. Sir Joseph J. Thomson, O.M., Pres.R.S., in the chair, to receive the report of the Executive Committee on the work of the previous six months.

The Report indicates that a number of important questions of scientific and industrial importance have occupied the attention of the Board. Various bodies are at present interested in the formation of a census of the mineral resources of the Empire. It was agreed to enter into communication with these bodies and to make suggestions with a view to the publication of information in a form useful to the general community.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Ferou 8, Paris (3e); Patent from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Embrittling action of sodium hydroxide on mild steel, and its possible relation to seam failures of boiler plates. Merica. See X.

PATENTS.

Nitration and sulphonation: Apparatus for—. J. W. Leitch, Huddersfield, and F. R. Lank-shear, Manchester. Eng. Pat. 105,775, Mar. 22, 1916. (Appl. No. 4264 of 1916.)

To cool the liquids undergoing nitration or sulphonation more effectively, the cooling pipes or coils are provided with gills.—W. H. C.

Mixing machines. E. Rhodes, Leeds, and F. E. Bristowe, London. Eng. Pat. 105,870, Nov. 4, 1916. (Appl. No. 15,763 of 1916.)

THE mixing blades, 11, are supported from the radiating arm, 1, by the extension piece, 10, having slots, 8, 9, which fit over the pins, 6, 7, in the bracket, 2. If the blade, 11, comes into contact with an obstruction, the extension piece, 10, slides upwards and backwards on the pins, lifts the blade over the obstacle, and drops it back again into position.—W. H. C.

Liquid fuel furnaces. F. W. Cotterill, Ltd., and G. R. West, Darlaston, Staffs., and J. Spencer, Walsall. Eng. Pat. 106,077, May 22, 1916. (Appl. No. 4262 of 1917.)

IS a liquid fuel furnace, which is particularly suitable for heating iron and steel bars in the manufacture of nuts and bolts, or for making drop stampings or forgings, the horizontal burner nozzle opens into a preliminary combustion chamber in front of the main heating chamber. Oil fuel and a hot air blast are supplied to the burner nozzle. The top of the heating chamber is closed by a removable slab having a central opening through which the waste gases escape. A preheating device for the air blast is placed just above the central opening, and a blast of secondary air is supplied by an additional pipe connecting it to a nozzle opposite the burner nozzle, so as to ensure complete combustion and mixing of the gases in the heating chamber.—W. F. F.

Tunnel muffle furnaces for burning ceramic ware and heating metals, chemicals, and other materials. H. T. Padelt, Leipzig-Schleussig. Ger. Pat. 295,987, Nov. 24, 1914.

THE heating flues built in, or adjacent to, the walls of the furnace decrease in cross-section from the lowest flue upwards, and each flue can be separately heated. The air for combustion is reheated in a series of flues similarly constructed n, or adjacent to, the walls of the cooling zone of the furnace, and these flues open into a common main flue, whence the air is conducted to different parts of the combustion zone.—C. A. M.

Drying sand and the like: Apparatus for—. A. A. Bratton, McVextown, Pa., Assignor to Pennsylvania Glass Sand Co., Lewistown, Pa. U.S. Pat. 1,224,132, May 1, 1917. Date of appl., July 16, 1913.

A VERTICAL drying chamber is provided with a number of superposed horizontal pipe coils over which sand passes. The pipes of the coils are of progressively smaller diameter, and the coils are closer, from the top downwards, the lowest coil forming a screen for the dried sand. Steam is passed through each coil separately, and the pipes of vertically adjacent coils extend in opposite directions from inlet to outlet. Moist air is withdrawn from the drying chamber and the dried sand is collected in a compartment below the lowest pipe coil.—W. F. F.

Separation of impurities from liquids by centrifugal force. J. Hamill, Honolulu, Hawaii. U.S. Pat. 1,224,164, May 1, 1917. Date of appl., Mar. 13, 1911.

A VERTICAL cylindrical rotary bowl, having an inverted conical bottom with a central opening, is provided with an annular conical partition similar to the bottom of the bowl and midway between top and bottom. Liquid is fed into the bowl near the bottom and passes out at the top, the overflow rim at the top being slightly nearer the axis than the rim of the central partition. The contents of the bowl are discharged downwards when it is brought to rest.—W. F. F.

Grinding in tube-mills. O. Schultz, Brooklyn, N.Y., Assignor to F. L. Smidth and Co., New York. U.S. Pat. 1,225,061, May 8, 1917. Date of appl., Feb. 12, 1911.

THE inlet chamber of a rotary tube-mill is of small diameter relatively to the co-axial outlet chamber, from which it is separated by a transverse perforated partition. The speed of rotation is such that the flint pebbles in the inlet chamber have a cascading action and the metallic grinding bodies in the outlet chamber take a continuous whirling path owing to the greater peripheral speed.

—W. H. C.

Distillation process. H. L. Doherty, New York. U.S. Pat. 1,225,226, May 8, 1917. Date of appl., July 16, 1912.

A GASEOUS medium is circulated in a closed circuit in contact with the liquid to be distilled, which moves in the opposite direction. The gas is heated at an intermediate point in its zone of contact with the liquid, to a temperature above the desired point of distillation. The vapour is taken up by the gas, which is then brought into contact with the initially cool liquid, so that vapour is condensed and the liquid preheated. The cooled gas is brought in counter-current into contact with the heated residual liquid to reheat the medium and cool the liquid.—W. F. F.

Liquids containing solids: Process for changing the consistency of—. I. S. Merrell, Assignor to Merrell-Soule Co., Syracuse, N.Y. U.S. Pat. 1,225,348, May 8, 1917. Date of appl., Oct. 19, 1916.

THE substance to be concentrated is caused to pass through a heated, vertical, centrifugal chamber whereby the solid portion travels upward and the liquid portion is given off as vapour to the interior

of the chamber, from which it is withdrawn. Means are provided for wiping the inner surface of the chamber.—W. H. C.

Condensing gas under high pressure: Apparatus for —. G. L. and J. J. Cabot, Boston, Mass. U.S. Pat. 1,225,574, May 8, 1917. Date of appl., Oct. 26, 1914.

A CLOSED, heat-insulated chamber is provided with horizontal partitions forming a zigzag passage, and a pipe coil follows the course of the passage, the lower end being connected to a flat, horizontal, closed vessel in the bottom of the

plated to prevent attack by pyridine) was used. Glass rods were placed in the basket carrying the charge prior to filling; on removing them the charge was loosened. Common salt or potassium sulphate was mixed with the coal to prevent caking during extraction. Though unaffected by the pyridine, they could be extracted with water from the residue at the end. The extract was concentrated by distillation *in vacuo*, and added to an excess of dilute hydrochloric acid which produced a brown precipitate. This was washed with water and dried *in vacuo*. The residue insoluble in pyridine was treated with water and hydrochloric acid and dried.

II A.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Solvents of —. A. Wahl, Bull. Soc. Chim., 1917, 24, 76—88.

THE author records extraction experiments with pyridine and quinoline on a series of coals, and results of examination of the residue and extract. The coal was powdered to pass a sieve of 900 meshes to the sq. cm., dried *in vacuo*, and extracted with boiling pyridine in a Soxhlet apparatus. Generally a large apparatus of copper (silver-

Generally speaking, the pyridine extract is large when the volatile matter is high, but there is no close parallelism. The volatile matter in the residue, compared with the original coal, is also reduced, excepting in those cases where the extraction is slight. The small increase in such cases is probably accidental and due to retention of pyridine. The residue has either reduced coking properties or else none at all, but extract and residue mixed will still coke. The pyridine extracts are brown powders, insoluble in water, acids, and alkali, but partially soluble in organic solvents giving fluorescent solutions. The extract is soluble in fuming nitric acid, and if the extract be first suspended in glacial acetic acid, oxidation is minimised. The product, on precipitation with water, resembles the original substance but is more combustible. The pyridine extract and also coals low in volatile matter, even anthracite, behave similarly. The coal from Lens (mine 8) was also extracted with quinoline. The extract at 120° C. was more than 4 times greater than with pyridine at about the same temperature. At the boiling point of quinoline (238° C.), 5.56% of the coal was extracted. At this temperature decomposition seemed to occur in addition to simple solution, for the residue had lost all coking properties and these could not be restored by mixing the extract with the residue. Ultimate analyses of the pyridine extract and the original coal were almost identical. The hydrogen and nitrogen contents of the extract were higher in the former case, due perhaps to retention of solvent. The methods of metallographic analysis were applied to some of the samples. A polished specimen of coal from Lens (mine 8) which gives a small pyridine extract, showed no change of structure after etching with pyridine. A sample from mine 3 showed dark areas which became more marked after etching. A sample of coal from Frankenholtz (seam X), which showed a perfectly polished surface before attack, disclosed granular bands after pyridine extraction.—H. J. H.

"Double gas" process. H. Strache. Z. Ver. Gas- u. Wasserfachm., 1916, 54, 301—309. Z. angew. Chem., 1917, 30, 106.

In the author's form of producer, the coal is first

carbonised and the coke produced is more or less completely gasified, yielding a mixed gas of calorific value about 3500 calories per cb. m. (395 B.Th.U. per cb. ft.). Even lignite can be treated, giving a gas of calorific value 3200–3400 cal. per cb. m. (360–280 B.Th.U. per cb. ft.). In character this double gas lies between water-gas and ordinary coal gas. It is cheaper than water-gas and requires about the same outlay on plant. Its calorific value exceeds that of water-gas although both have the same flame temperature. Its advantages as an auxiliary to town gas manufacture are similar to those of water-gas and are summarised as follows:—1. The plant is always ready for action. 2. Smallness of floor-space and capital outlay required. 3. Cheapening of running costs because of continuity of operation. 4. Possibility of controlling coke prices. 5. Mechanical operation. The "double gas" can be led directly into the crude gas main if the exhauster is powerful enough; but even alone it can be used satisfactorily in incandescence burners with proper regulation of air supply. It is also suitable for industrial purposes.—H. J. H.

Toluene extraction [from coal gas]. H. C. Applebee, Manchester and District Jun. Gas Assoc. Gas J., 1917, 138, 338–340.

THE "C" process, in which the gas is washed by coal tar or carburetted water-gas tar, has not been entirely satisfactory and in the majority of cases oil-scrubbing processes have been substituted. These processes vary in the form of washer or scrubber and in the nature of the wash oil used. Centrifugal washers are being used, it is claimed, with more success than any other form. At the Bradford Road works of the Manchester Corporation, tower scrubbers packed with wood laths are used with decided success. Results of tests showed that coal tar creosote was more suitable as a washing medium than petroleum (gas oil), the latter also presenting difficulties in the recovery of the extracted products. Wash oil should not contain any large amount of naphthalene, the sp. gr. should be over 1.00, and the specific heat should not be too high. Tests as to the effect of the treatment on the illuminating power of the gas suggest that there is a point of maximum reduction, this point in the experiments being reached at about 924 gallons of wash oil per 10,000 cub. ft. By calculation from analyses the reduction in heating value was estimated at about 6 to 8%. Tests with petrol showed that in replacing the benzol extracted a more volatile spirit gave better results but was not quite as successful as benzol is reputed to be. Many conditions affect the amount of products recovered from gas, viz., amount of wash-oil used, quality of wash-oil, temperature of oil and gas, circulation of oil, mechanical efficiency of the scrubbers (packing, number in use, etc.). At Bradford Road the amount of wash-oil used has varied from 70 to 105 galls. per ton of coal, the lower rate always being accompanied by a diminution in crude benzol recovered. It is advisable to change the oil when its sp. gr. rises to 1.06 to 1.065, or when the distillation shows less than 50% at 300° C. Temperatures at the scrubbers should be kept down to 25° C. and a suitable degree of saturation of wash-oil is 3%. The author's tests showed an efficiency of 75 to 78% when using three scrubbers and 74 galls. of wash-oil per ton, the figure rising to 88% on using six scrubbers and 108 galls. of wash-oil per ton. Carburetted water-gas has recently been scrubbed, giving a yield of 2.5 to 2.8 galls. per 11,000 cub. ft. The Simon-Carrès recovery plant consists of a still proper, heat interchanger, dephlegmator, superheater, and two tubular condensers. Rich oil passing through the first condenser helps to cool the benzol vapours and

is itself heated to 50° C.; in the dephlegmator its temperature reaches 65° C., in the heat exchanger 80° C., and in the superheater 120° C. In the still proper it is brought into contact with open steam, and passes thence through the heat interchanger to the oil coolers. The benzol vapours pass through the dephlegmator and the first condenser, and condensation is completed in the last water-cooled condenser. The crude benzol is worked up in a Dempster still of 5000 galls., giving 60% of once-run benzol and 15% of once-run toluol, the residues being run off and cooled to separate naphthalene. The once-run benzol and toluol are washed separately with sulphuric acid (sp. gr. 1.84), in a washer of a capacity of 2500 galls. Acid is added in two portions of 5 and 46 galls. respectively. After agitation, settling, and washing with water the benzol is washed with caustic soda (20 Tw., sp. gr. 1.1) and finally with water. The loss in washing is estimated at 7%. The washed product is re-fractionated in a still of the Dempster type, intermediate products being put back for re-working, and residues being run to the naphthalene trays.—J. E. C.

Aromatic hydrocarbons from the thermal decomposition of natural gas condensate. J. E. Zanetti and G. Egloff. J. Ind. Eng. Chem., 1917, 9, 471–478.

THE fraction of a natural gas condensate (from West Virginia), composed mainly of butanes, propane, and ethane, was subjected to thermal decomposition at about 900° C. in an electrically heated tube furnace, and the product passed through a Cottrell (electrical) separator to effect complete precipitation of the tar "fog" formed. The 1.5 kilos. of tar thus obtained (sp. gr. 1.109) was separated into fractions boiling up to 170°, 170°–230°, 230°–270°, 270°–330°, 330° to above 360° C., and residue (the proportions found being 9.7, 18.7, 11.1, 15.1, not stated, and 39.1% by weight, respectively) and from these benzene, toluene, naphthalene, acenaphthene, anthracene, phenanthrene, pyrene, and chrysene were isolated.—W. E. F. P.

Sulphur in petroleum: Detection and determination of —. C. K. Francis and C. W. Crawford. J. Ind. Eng. Chem., 1917, 9, 479–481.

FROM an investigation of oils from the Mid-Continent (U.S.A.) Field, especially of those from the Bartlesville sand in the Cushing pool, it is concluded that the "methylene blue" test provides an extremely delicate reaction for the detection of any form of sulphur in petroleum and may also be used for determining the presence of hydrogen sulphide. The oil is heated with excess of sodium, the residue extracted with water, and the solution neutralised with hydrochloric acid, of which a 10% excess (by volume) is then added. A small crystal of *p*-aminodimethylaniline sulphate is then dissolved in the liquid and several drops of dilute ferric chloride solution added, when the presence of sulphur is indicated by the development of a blue coloration which becomes more intense on standing or changes to violet if cyanides are also present. For the determination of sulphur in petroleum, satisfactory results for crude oil were obtained by heating with sodium peroxide in a Parr bomb, and also by a modified Dammer combustion method in which the oil was burnt in a stream of oxygen, the products passed through a strong solution of hydrogen peroxide, and the acidity of the latter determined by titration with standard alkali after decomposition of the excess of peroxide by boiling. No hydrogen sulphide or carbon bisulphide was found in the Bartlesville oil, most of the sulphur being probably in the form of alkyl sulphides.—W. E. F. P.

Ignition point of oxy-hydrogen gas. Mitscherlich.
See VII.

PATENTS.

Washing coal, coke breeze, and other minerals; Apparatus for —. W. Taylor, Ossett, Yorks. Eng. Pat. 105,835, July 10, 1916. (Appl. No. 9668 of 1916.)

COAL, coke, breeze, or other mineral is impelled by a stream of water along an inclined trough fitted with baffles or detachable partitions. The inclination of the trough may be varied by adjusting a vertically movable sling, and means are provided for imparting a rotary or semi-rotary movement to the trough, whereby the heavier impurities retained by the baffles may be discharged.—J. E. C.

Coal; Non-abrusion process and apparatus for washing and sorting —. H. Adams, Assignor to the Adams Mining Machinery Corporation, New London, Conn. U.S. Pat. 1,221,350, May 1, 1917. Date of appl. May 11, 1916.

COAL, or other mineral, or ore or the like is allowed to drop freely through the apparatus. Individual jets of water under pressure are directed from one side against the falling material. The various elements are deflected according to their respective gravities and fall into separate troughs at the bottom of the apparatus.—J. E. C.

Coke breeze and similar materials; Apparatus for washing —. W. H. Orbell, Wakefield, Eng. Pat. 105,817, May 25, 1916. (Appl. No. 7410 of 1916.)

COKE breeze or other similar material is agitated in a funnel-shaped tank by a steel screw spinner. The discharge valves for scale are operated alternately by a crank with opposite throws, and sufficient water is retained in the tank to make the process continuous.—J. E. C.

Coal; Process and apparatus for treating [briquetting] —. C. H. Smith, Short Hills, N.J. U.S. Pat. 1,221,121, May 1, 1917. Date of appl. May 5, 1916.

COAL is heated to expel a substantial portion of the volatile matter and to convert it into a plastic mass which is kept agitated. Whilst in this state the coal is removed from the heating zone, freed from "entrained" gases, and compressed into a briquette.—J. E. C.

Coal; Method of treating [briquetting] —. C. E. Hite, Burlington, N.J., Assignor to Universal Briquetting Co. U.S. Pat. 1,224,641, May 1, 1917. Date of appl. June 21, 1909. Renewed Oct. 6, 1916.

PULVERISED coal is dried, mixed with crude petroleum oil, and subjected to a temperature of approximately 400° F. (about 200° C.). Water is then added to stiffen the oily portion of the mixture, which is moulded into blocks or briquettes and subjected to a temperature of 500 to 600° F. (about 260 to 320° C.).—J. E. C.

Furnace with vertical retorts and producers beneath the retorts. Bunzlauer Werke Lengersdorf und Co., Bunzlau, Ger. Pat. 297,252, Jan. 20, 1916. Addition to Ger. Pat. 293,061 (this J., 1916, 958).

ABOVE the burners and below the regenerator chambers is built a horizontal flue which receives and leads away the products of combustion from all the groups of burners. The accessibility of the different parts of the setting is improved and control is easier than when a separate flue is provided for each group of burners.—H. J. H.

Gas producers. W. H. Bricknell, Te Kuiti, and A. Burt, Auckland, N.Z. Eng. Pat. 100,730, Apr. 13, 1916. (Appl. No. 5150 of 1916.) Under Int. Conv., June 22, 1915.

THE efficiency of producer gas manufacture can be increased by utilising the heat radiated from the walls. The producer is enclosed in an iron shell and the air, or air-steam supply, enters the annular space thus formed, and in rising upwards becomes preheated by radiation from the producer wall. At the top it enters pipes built into the wall and is conveyed downwards into a blast chamber, the inner wall of which is perforated, so that the warmed blast can be uniformly distributed into the charge. These perforations slope downwards to avoid the entry of coal, etc., into the blast chamber.—H. J. H.

Gas generators. W. P. Tinsley and J. G. Nash, Fort Worth, Tex., U.S.A. Eng. Pat. 105,788, Apr. 25, 1916. (Appl. No. 5902 of 1916.)

A GAS generator tank, not affected by acids used in manufacturing gas, and capable of resisting internal pressure, is constructed of reinforced concrete and comprises a base fitted with an outlet pipe, walls, and a cap. The tank is filled with gas-making material and means are provided for feeding hydrocarbon oils and acids.—J. E. C.

Hydrogen retorts; Treatment and utilisation of gases supplied to the furnaces of —. J. M. Ballingall, and R. and J. Dempster, Ltd., Manchester, Eng. Pat. 106,067, Jan. 6, 1917. (Appl. No. 290 of 1917.)

SPENT water-gas from a hydrogen-retort plant is preheated in a regenerator and passed through the reaction zone of a gas producer. The dissociated gas is burnt together with producer gas in the region of the retorts with a deficiency of air so as to form a reducing atmosphere at that point. On leaving this region any unburnt gases are consumed by a further addition of air and give up a portion of their heat to the incoming spent water-gas in a continuous counter-current regenerator.—J. E. C.

Producer gas; Manufacture of — [from powdered coal]. J. E. Bell, New York, U.S. Pat. 1,223,242, Apr. 17, 1917. Date of appl. July 17, 1915.

THE producer consists of two narrow chambers built side by side, communicating at the bottom with each other and with separate regenerators at the top. Powdered coal is allowed to fall down one chamber in a current of hot air from the appropriate regenerator. Partial combustion occurs and the producer gas formed passes up the second chamber, clinker being deposited at the bottom, and from the top into the second regenerator which becomes heated while the gas is at the same time cooled. At regular intervals the current is reversed and the second chamber becomes the gasifier, and its regenerator heated by the producer gas now warms the air supply.—H. J. H.

Gas producer. E. Nimphius, Evanston, Ill., Assignor to J. H. Whitaker, Chicago, Ill. U.S. Pat. 1,225,018, May 8, 1917. Date of appl. Apr. 23, 1915.

A GAS producer comprises a stationary combustion chamber, a rotary conical grate, and a stationary ash platform beneath the grate. Air is introduced through passages in the grate at an inclination opposite to the direction of rotation, and a revolving scraper blade co-operates with the ash platform.—J. E. C.

Carbonic oxide; Method of producing —. G. H. Benjamin, New York, U.S. Pat. 1,225,390, May 8, 1917. Date of appl. June 7, 1911.

COAL is decomposed in a producer by the high temperature effects of mixed furnace gases and air,

and an electric current is transmitted through a portion of the coal in the producer, whereby the liberated carbon dioxide and that present in the furnace gases is decomposed, and combines with carbon to form carbon monoxide.—J. E. C.

Distillation gases from coal: Purification of—
E. Ciselet and C. Deguide, Brussels, Ger. Pat. 297,101, July 6, 1915.

THE gas is washed with an ammonia liquor containing lime in suspension. The ammonia combines with the acidic constituents of the gas, which are then fixed by the lime, as calcium salts, the ammonia being regenerated. The ammonia is therefore not consumed, but acts merely as a carrier. After filtering, and boiling to expel ammonia, the liquor may be treated with an iron salt to fix cyanides and with carbon dioxide to expel hydrogen sulphide.—H. J. H.

Gaseous fuel for internal combustion engines: Production of—
A. W. Southey, London, Eng. Pat. 105,606, Apr. 18, 1916. (Appl. No. 5668 of 1916.)

INTERNAL combustion engines may be fed with liquid fuel, *e.g.*, paraffin, vaporised by a flame burning freely in air at a wick dipping into the reservoir of oil. The flame, drawn by suction from the engine, impinges on a vertical tube communicating with the oil reservoir and kept full by the suction of the engine. The oil in this tube is vaporised. The vapours, mixed with flame gases and air, are drawn into a wide tube standing over the oil-feed tube and thence to the engine. The supply of fuel and air is regulated automatically by the suction of the engine, and as the oil is merely vaporised, without cracking or combustion, the calorific power of the original oil is fully utilised. In an alternative device the flame impinges on the surface of the oil maintained at constant level and excluded from contact with air. The oil is vaporised and carried to the engine as before.—H. J. H.

Crude oil: Treatment of—
Apparatus for treatment of natural oils and residues of same. W. S. Barnickel, St. Louis, Mo., U.S. Pats. (A) 1,223,659 and (B) 1,223,660, Apr. 24, 1917. Dates of appl., Nov. 19, 1914, and Mar. 6, 1916.

(A) CRUDE mineral oil in the form of an emulsion of petroleum, brine, and other organic matter is clarified by intimately admixing a small quantity of a soluble water-softening agent capable of precipitating the alkaline earths present in the emulsion. The precipitate carries down insoluble salts of calcium, etc., and organic matter, and the brine and petroleum then separate into two layers. As precipitants, soluble carbonates, sulphates, hydroxides, fats or other soap-making materials are proposed. (B) An apparatus suitable for the process consists of a vat furnished with a vertical central pipe having numerous fine jets. The precipitant is forced through these jets into the contents of the vat. The aqueous liquor and precipitate settle out at the bottom of the vat and may be drawn off and returned by means of a pump to the jets.—H. J. H.

Mineral oils: Process of transforming—
[into terpenes and aromatic hydrocarbons]. A. S. Ramage, Assignor to Bostaph Engineering Co., Detroit, Mich., U.S. Pat. 1,224,787, May 1, 1917. Date of appl., Apr. 27, 1916.

PARAFFINS and olefines are transformed into terpenes and aromatic hydrocarbons by subjecting them in the state of vapour to restricted oxidation by iron oxide at a temperature of 580° to 750° C.—J. E. C.

Combustible fluids: Process of securing—
from carbonaceous solids. J. H. Reid, Newark, N.J., Assignor to Patents Process Co., U.S. Pat. 1,224,788, May 1, 1917. Date of appl., Aug. 26, 1915.

COMBUSTIBLE fluids are obtained from carbonaceous solids, *e.g.*, shale, by mixing them with charcoal and passing electricity through the mixture until the desired product is evolved.—J. E. C.

Liquid fuel composition and process of making same. A. W. Swanberg, Minneapolis, Minn., Assignor to F. C. Fisk, Williamsville, N.Y., U.S. Pat. 1,225,405, May 8, 1917. Date of appl., June 23, 1916.

LIQUID fuel for internal combustion engines and the like is prepared by dissolving anthracene in carbon bisulphide in the presence of moisture and mixing the solution with kerosene. The proportions of anthracene and carbon bisulphide in the resulting mixture are specified as about 2 oz. and 6 oz. per gallon respectively.—J. E. C.

Petroleum products: Process and apparatus for transforming heavy—
into lighter products. F. B. Deakin, London, From P. Roth and M. E. Venturino, Buenos Aires, Argentine, Eng. Pat. 106,042, Sept. 20, 1916. (Appl. No. 13,363 of 1916.)

SEE U.S. Pats. 1,208,214 and 1,208,378 of 1916; this J., 1917, 126.

Mineral oils and residues: Treatment of—
for the production of lower-boiling hydrocarbons. C. White, London, U.S. Pat. 1,226,041, May 15, 1917. Date of appl., May 13, 1914.

Electric glow lamps: Carbon filament—
C. O. Bastian, London, Eng. Pat. 105,929, Jan. 26, 1916. (Appl. No. 1271 of 1916.)

A CARBON filament electric glow lamp comprises an air-tight globe, containing an atmosphere of inert gas and a carbon filament in the form of a spiral of very small diameter, manufactured by winding a thread of cellulose in a single continuous layer on a mandril of small diameter, removing the mandril, and carbonising the spiral.—J. E. C.

Electric glow lamps. C. O. Bastian, London, Eng. Pat. 106,036, Jan. 26, 1916. (Appl. No. 11,968 of 1916.)

IN the manufacture of incandescence electric lamps, etc., the globe is filled with an inert gas and the lamp freed from oxygen by the prolonged and combined effect of chemical action and externally applied heat. A de-oxidising liquid, such as fused sodium nitrite at about 280° C., may be used to combine with the oxygen.—J. E. C.

III.—TAR AND TAR PRODUCTS.

Frag carbon in coal tar : Determination of —, P. Falcicola. *Annali Chim. Appl.*, 1917, 7, 152—157.

The following modification of Ceruti's method (this J., 1911, 111) is proposed:—About 5 grms. of the coal tar is added little by little to 125—150 c.c. of olive oil, which has previously been heated to 110—160° C., and the mixture is brought to about 180—190° C., and then cooled to about 150° C. and filtered through a counterpoised filter. The residue of carbon in the basin is again heated with 50 to 75 c.c. of the oil at 180—190° C., and the oil extract cooled to 150° C. and passed through the same filter. The residue is then transferred to the filter by means of carbon tetrachloride or other, washed until free from oil with the same solvent, dried, and weighed. The amounts of carbon thus determined in various types of coal-tar agreed very closely with those determined by Lange's method. Naphthalene is soluble in its own weight of olive oil at 65° C., whilst the solubility of anthracene is 5% at 100° C., and 26% at 180° C. Castor, linseed, sesame, and vaseline oils have a very similar solvent action upon naphthalene and anthracene.—C. E. M.

Maplewood creosote : Chemical composition of the higher fractions of —, E. J. Pieper, S. F. Acree, and C. J. Humphrey. *J. Ind. Eng. Chem.*, 1917, 9, 162—165.

A COMMERCIAL sample of maplewood creosote yielded 75% of wood creosote and 25% of pitch. About 14% of the creosote distilled at 93° to 195° C., 31% at 195° to 230° C., and 55% at 230° to 280° C. On extracting the different fractions distilling above 195° C. with alkali they yielded from 70 to 85% of phenols, some of which were separated as sodium salts. The phenols consisted chiefly of pyrogallol-dimethyl-ether, and a small quantity of propyl-pyrogallol-dimethyl-ether, and were therefore identical with those found in beechwood creosote, although present in different proportions.—C. A. M.

Aniline from ammonia and benzene at high temperatures and in presence of contact substances : Formation of —, J. P. Wibaut. *Ber.*, 1917, 50, 511—516.

MEYER and TANZEN (this J., 1913, 1060) have stated that aniline is formed by the action of ammonia on benzene at 550° C. The author, however, finds that ammonia is without action on benzene in a porcelain tube until a temperature of 700° C. is attained, when a trace of aniline is produced. In presence of freshly reduced iron, copper, or nickel, somewhat larger amounts of aniline were formed.—F. W. A.

Diphenyl derivatives : Some new —, W. Borsche and B. G. B. Scholten. *Ber.*, 1917, 50, 596—611.

As a starting point for researches on *o*-hydroxydiphenyl derivatives, phenylbenzoquinone-3-oxime was employed, obtained by the action of diazobenzene chloride on an alkaline solution of quinone-oxime. With nitric acid it gave a dinitrohydroxydiphenyl, which is shown to be a 3,5-dinitro derivative with both nitro groups in the same nucleus. This was proved by Ullmann and Nadai's reaction, by warming with *p*-toluene sulphochloride and dimethylaniline; there were obtained about equal proportions of an ester of *p*-toluenesulphonic acid and 3,5-dinitro-2-chlorodiphenyl. These observations have been utilised in experiments with the commercially obtainable *o,o*-dihydroxydiphenyl, which when treated in glacial acetic acid solution with nitrous acid readily gives diquinone-3,3'-dioxime, from which may be obtained the diamino-dihydroxy derivative and

thence diquinone. Nevertheless the two latter may be more conveniently prepared by the reduction of 5,5'-dibenzeneazo-2,2'-dihydroxydiphenyl by hydrosulphite and dilute alkali. 3,5,3',5'-Tetranitro-2,2'-dihydroxydiphenyl was also treated with *p*-toluenesulphochloride and dimethylaniline but did not yield the expected toluenesulphonic ester and tetranitro-2,2'-dichlorodiphenyl derivative; instead there was exclusively obtained 3,5,3',5'-tetranitrodiphenylene oxide. When 2,2'-dimethoxydiphenyl is nitrated in presence of much sulphuric acid it yields 3,5,3',5'-tetranitro-2,2'-dimethoxydiphenyl, and this when heated with alcoholic ammonia at 150° C. passes easily into 1,3,6,8-tetranitrocarbazole. Failure to obtain the tetranitro-*o,o*-dichlorodiphenyl led the authors to make parallel researches with the *m,m'* and *p,p'* isomerides. In the case of the *p,p'* derivative the application of Ullmann's reaction to tetranitro-4,4'-dihydroxydiphenyl, obtained from benzidine, gave only a di-*p*-toluenesulphonic ester, while the nitration of *p,p'*-dichlorodiphenyl yielded only a dinitro compound with the nitro groups in the *meta* position to the chlorine. On the other hand, *m,m'*-dichlorodiphenyl easily gave 2,4,2',4'-tetranitro-5,5'-dichlorodiphenyl because both the chlorine and the phenyl influence the entry of the nitro groups in the same sense.—J. F. B.

Toluene extraction [from coal gas]. Applebee. See II A.

Aromatic hydrocarbons from thermal decomposition of natural gas condensate. Zanetti and Egloff. See II A.

PATENTS.

Toluol : Manufacture of —, W. H. Gartley, Assignor to The United Gas Improvement Co., Philadelphia, Pa. U.S. Pat. 1,225,237, May 8, 1917. Date of appl. Mar. 30, 1916.

COAL tar naphtha is distilled under a pressure of about 35 lb. per sq. in. and is thereby converted into a lighter portion from which toluol may be recovered, and a heavier portion which is redistilled under atmospheric pressure, the recovered naphtha being again submitted to the pressure distillation process.—W. H. C.

Nitro aromatic compound and process of making same. J. R. Mardick. New York. U.S. Pat. 1,225,317, May 8, 1917. Date of appl. June 6, 1916.

IMPURE tar is nitrated by relatively weak acid at a temperature between 10° and 60° C. The strength of the acid is then increased and the temperature allowed to rise to between 70° C. and 90° C. The mass is allowed to stand until separation takes place, the lower watery liquid is drawn off, and the upper practically solid layer treated with strong nitric and fuming sulphuric acids between 95 and 105° C.—W. H. C.

Ketones of the thiophene series : Preparation of —, W. Steinkopf. Berlin-Halensee. Ger. Pat. 297,203, Nov. 7, 1911.

KETONES can be prepared by treating thiophene with acid chlorides (aliphatic and aromatic) in the presence of phosphorus pentoxide. Combination takes place, with the elimination of hydrochloric acid, on simply heating the substances together under a reflux condenser, and satisfactory yields are obtained.—H. J. H.

Benzoyl derivatives of 3-hydroxy- or α,β -di- and poly-hydroxyanthraquinones : Preparation of —, R. Wedekind und Co., Uerdingen. Ger. Pat. 297,261, Mar. 9, 1915.

THE process applies particularly to 2-hydroxyanthraquinone, 2,6- and 1,2-dihydroxyanthraquinone, and 1,2,6- and 1,2,7-trihydroxyanthraquinone,

which are treated with benzoic acid with or without the addition of sulphuric acid. The weight of benzoic acid taken is ten to fifteen times that of the hydroxyanthraquinone, and although the sulphuric acid accelerates the reaction it is not essential. The reaction is completed by heating the mixture at atmospheric pressure. The process obviates the employment of benzoyl chloride.—H. J. H.

Apparatus for nitration and sulphonation. Eng. Pat. 105,775. See I.

Process of transforming mineral oils [into aromatic hydrocarbons]. U.S. Pat. 1,224,787. See IIa.

Process of nitrating toluols containing paraffins. U.S. Pat. 1,225,324. See XXII.

IV.—COLOURING MATTERS AND DYES.

Isatin salts: Constitution of the blue——. M. Claass. Ber., 1917, 50, 511—515.

THE view of Heller (Ber., 1916, 49, 2757) that the blue or bluish-violet alkali salts of isatin and its derivatives are not O-salts but N-salts is considered incorrect, as N-salts are decomposed by water, whereas the blue isatin salts are produced in aqueous solution in which they are relatively stable. On the same grounds Heller has stated that the formulae recently advanced for the sodium salt of sulphurylindoxyl- α -indole-indigo and for indigo (Claass, this J., 1916, 1150) are incorrect, the tinctorial power of the latter being considered to be entirely due to the stilbene linkage, C=C; the formulae proposed by Heller for the sodium salt of isatin as a N-salt does not include a chromophore or a double linkage. Heller suggests that all N- and C-salts are blue, and that all O-salts are red; it is considered that the chemical behaviour of these compounds is more decisive than their colours. Heller (*loc. cit.*) has found the third isomer of isatin, isatol, to be a weak phenol which yields a relatively stable sodium salt (I). In aqueous solution the blue N-sodium salt of isatin is converted into the yellowish-red O-salt. The blue salts of isatin

soluble in water without alteration in colour are considered to be derived from the β -form with the quinonoid nucleus (II). The deep blue-black colour of the N-sodium salt of isatin is probably due to a betaine-like grouping of the carbonyl oxygen with quinquivalent nitrogen (III).—F. W. A.

Azine dyestuffs: Notes on——. F. Kehrmar. Ber., 1917, 50, 554—563.

DETAILS are given of the preparation of phenyl-apsafranine and its reactions with aniline. The product obtained by the action of aniline on the 2-amino-derivative of Flavinduline (phenyl-phenanthrenazonium) has been synthesised from phenanthraquinone and 4,6-dianilino-1,3-phenylenediamine, and the dyestuff from benzil and 4,6-dianilino-1,3-phenylenediamine has been prepared. The introduction of aryl groups into indamines of the type of Toluyene Blue only increases their fastness to washing and not to acids or to light.—F. W. A.

Bixin. A. Heiduschka and A. Panzer. Ber., 1917, 50, 546—551.

THE varying formulae for bixin suggested by Van Hasselt (this J., 1914, 677) and Herzig (this J., 1915, 866) and others are attributed to the use of different extracting and recrystallising agents. Bixin from glacial acetic acid and ethyl acetate has a methoxyl content of 8.03%, corresponding to the formula, $C_{25}H_{30}O_4$, given by Pregl (see Herzig, *loc. cit.*) from the results of micro-analysis.—F. W. A.

PATENTS.

Anthracene vat dyestuffs: Manufacture of——. R. Wedekind and Co., Uerdingen. Ger. Pat. 297,080, Sept. 16, 1913. Addition to Ger. Pat. 296,207 (see Eng. Pat. 19,435 of 1913; this J., 1914, 415).

ANTHRAQUINONE itself or a reduction product, e.g., anthranol, in place of its sulphonic acids or their salts, as claimed in the main patent, is heated with thiosulphates. The products are insoluble in water, alkali, and sodium sulphide, and dye cotton from an alkaline vat olive to olive-brown shades similar to, but faster to chlorine than, the products of the main patent.—F. W. A.

Azo dyestuffs: Manufacture of insoluble——. Badische Anilin und Soda Fabrik. Ger. Pat. 297,185, Nov. 20, 1914. Addition to Ger. Pat. 295,025 (this J., 1917, 78).

ARYLIDES of acetoacetic acid are used in place of ethyl acetoacetate claimed in the main patent. Coupling may be effected in alkaline solution, and in presence of Turkey-red oil or similar substance, or substrata generally used in pigment manufacture may be added.—F. W. A.

Monoazo dyestuffs: Manufacture of—— suitable for the production of pigments. Badische Anilin und Soda Fabrik. Ger. Pat. 297,414, Sept. 4, 1914. Addition to Ger. Pat. 296,991 (this J., 1917, 592).

IN place of 1-benzoylamino-7-hydroxynaphthalene or its derivatives substituted in the benzoyl nucleus claimed in the main patent, their N-alkyl derivatives are used. The latter are obtained by the action of benzoyl chloride or its substituted derivatives, in presence or absence of reagents to neutralise the acid produced, on the 1-alkylamino-7-hydroxynaphthalenes, obtained by alkaline fusion of the corresponding sulphonic acids.—F. W. A.

Process of obtaining sodium sulphate and sulphur from sodium thiosulphate [e.g., residues from the manufacture of sulphur dyes]. Ger. Pat. 295,859. See VII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Sulphite-cellulose: Recovery of the free sulphur dioxide from the blow-off gases and liquors in the digestion of——. A. D. J. Kuhn. Wochenbl. Papierfabr., 1916, 2139, 2179, 2233, and 2270. Chem.-Zeit., 1917, 41, Rep., 118.

IN modern sulphite pulp mills, working with fine pyrites in mechanical roasters, the latter only give satisfactory results when operated near the limit of their capacity, and there is little margin for variations in output. The liquor reservoirs must be large enough to cover two days' consumption, in order that the operations may not be suspended in the event of troubles in the liquor preparing department. Arrangements must also be provided for the complete utilisation of the sulphur dioxide from the gases and liquor blown off during the digestion for enriching the fresh liquor. The

liquor blown off along with the gas will contain organic matters as soon as the attack on the wood has commenced, and the gas must be separated from this liquor before it is admitted to the absorption plant. Three different types of arrangement for dealing with the blow-off gases are described:—(1) Those in which the blow-off gases and liquor are taken off together, cooled, and conducted to the absorption plant which is full of liquor. (2) Those in which the blow-off liquors are discharged from the digesters separately from the gases. (3) Those in which the separation of the gas and liquor is effected in a special vessel outside the digester. One of the last-mentioned type has a special gas separator by which the gas is conducted to an absorption tower packed with Raschig rings or blocks of wood; the clear liquor which is separated at first, is cooled and passed to a tower filled with limestone for conversion into fresh liquor, and the impure liquor which comes over later is run to the waste-liquor tank. The hot water which results from the cooling of the blow-off gases is pumped to an upper tank and utilised for washing the pulp in the digester. To illustrate the effect of the introduction of such a plant on the composition of the fresh digestion liquor, a case is quoted in which the sulphur dioxide content of the fresh liquor was raised from 3.43 to 5.58%, while the lime was reduced from 1.07 to 0.99%.—J. F. B.

Oil of turpentine recovered in the digestion of sulphate wood pulp. Halse and Dedichen. *See* XIII.

PATENTS.

Yarn and other materials: Conditioning apparatus for —. T. Andrew, Manchester. Eng. Pat. 165,789, Apr. 25, 1916. (Appl. No. 5927 of 1916.)

THE conditioning chamber has suction and delivery parts connected with the suction and delivery of a fan or its equivalent, one part, at the fan-delivery side, receiving air in the form of several currents delivered in parallel, whilst the other part, connected with the fan suction pipe, receives the air after its passage through the material, this air being withdrawn from the chamber, also in the form of several currents; means are provided for supplying independently regulated amounts of moisture to the various parallel currents of air and for introducing a separate supply of air at the entrance end of the chamber. The material to be treated is passed through the chamber on trucks or trolleys and the parallel currents of air are passed through it both upwards and downwards; elevators are provided at the entrance and exit ends for the material. The trucks or trolleys for carrying the yarn form divisions between the upper and lower portions of the chamber to ensure that the air passes through the receptacles, and after their discharge they are returned to the inlet by a runway beneath the chamber.—J. F. B.

Fibrous and other bodies: Apparatus for conditioning and dehydrating —. G. H. Benjamin, New York. U.S. Pat. 1,225,211, May 8, 1917. Date of appl., Aug. 1, 1911.

THE apparatus comprises an air filter, an air-feed main, a waste-air main, a series of drying cells interposed between the air feed and the waste air mains, with air passages connecting them with both mains, means in the air passages from the feed main for changing the direction of movement of the air currents through the cells, and supplemental air-heating devices, in proximity to each of the cells, controlling the temperature of the air currents passing through the cells. A weighing apparatus is provided for each cell and means

structurally independent of the weighing apparatus, but operated by it, for indicating the change in weight of the material contained in the cell.

—J. F. B.

Cotton and cotton goods and other combustible substances: Treatment of — to render them permanently less inflammable. W. H. Perkin, Oxford, and S. Bradbury, Ashton-upon-Mersey. U.S. Pats. 1,221,204 and 1,221,205, May 1, 1917. Date of appl., July 31, 1911.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Capillary phenomena and their importance in technical processes [dyeing, etc., and ore concentration]. S. A. Shorter. *J. Soc. Dyers and Col.*, 1917, 33, 107—111.

THE tendency to include under the term "capillarity" the whole of the phenomena presented by colloids is incorrect; the physical surface possesses a thickness of 10—50 $\mu\mu$, and the particles of a solution of albumin, for example, are much smaller than this and hence do not possess a physical surface to which can be applied the method of treating molecular forces in bulk, which forms the basis of the theory of capillarity.

Technical applications of surface tension phenomena are: (1) in calico-printing the treatment of fabric with a water-soluble oil to reduce the dye solution-fibre tension to practically zero and assist the wetting of the fabric; (2) the removal of grease after addition of soap to the water to bring about wetting by lowering the water-air and water-grease tensions; (3) the Elmore process for separating metallic sulphides from silicious matter, and other preferential wetting processes, such as the selective removal of diamonds from aqueous suspension by means of grease, the "flotation process" of separating minerals by bubbles of gas in presence of oil, etc. An explanation is advanced of the efficacy of foam in producing thorough wetting by a small amount of liquid, e.g., in foam dyeing.—F. W. A.

PATENTS.

Sizing solution, and method of making the same. M. N. Aisen, Chicago, Ill. U.S. Pat. 1,221,125, May 1, 1917. Date of appl., Apr. 28, 1914.

A NEUTRAL alcoholic solution containing glue is hydrolysed by an acid.—J. B. C. K.

Thickening agent for printing colours and sizing. M. and P. A. Zaesle, Pilsen, Bohemia, Ger. Pat. 295,670, Apr. 9, 1911. Under Int. Conv., July 1, 1913.

ROOTS, such as manioc and arrowroot, rich in starch, gums, and fats, are ground and winnowed in such a way that the cellulose is separated, practically completely, from the starch, which retains the fat and gums. The resulting product is then treated with acids or oxidising agents to obtain a gelatinous adhesive mass suitable for thickening printing colours, or as an adhesive paste which does not lose its stickiness when kept.—C. A. M.

Weighting, firing, mordanting, dyeing, and bleaching silk, artificial silk, cotton, wool, and other textile materials. R. Clavel, Assignee of Soc. de Teinture et d'Apprêt, ci-dev. A. Clavel et F. Lindenmeyer, Basle, Switzerland, Eng. Pat. 103,638, Oct. 21, 1916. (Appl. No. 15,118 of 1916.) Under Int. Conv., Jan. 25, 1916.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitrogen oxides from ammonia; Use of — in the lead chamber [sulphuric acid] process. H. Petersen. Metall u. Erz, 1916, 197, 204. Chem.-Zeit., 1917, 41, Rep., 70.

THE direct use of the nitrogen oxides obtained by the Frank-Caro process of oxidising ammonia, is not recommended owing to practical difficulties, loss of unoxidised ammonia, etc. A condensing plant, consisting of nine Pützer towers for oxidation and preliminary condensation, followed by three towers for the main condensation, is the most economical of any yet devised, the all-in working cost for a yield of 1200 kilos. of nitric acid (36° B., sp. gr. 1.332) per 24 hours being M. 0.60 per 100 kilos.—E. H. T.

Nitric acid vapour; Absorption spectrum of —. K. Schaefer and S. Deichsel. Z. anorg. Chem., 1916, 98, 70—76. J. Chem. Soc., 1917, 112, ii, 186.

ON account of the rapid decomposition of nitric acid vapour by light, it was necessary to maintain a stream of the vapour through the absorption tube during the photographing of the spectrum. The absorption tube was electrically heated at 130° C., the constant boiling acid being used. There is no absorption band, the curve being very similar to that given by liquid 98.7% acid. The NO₃ group in the vapour is therefore in a similar state to that in the alkyl nitrates and in the concentrated acid.

Nitric and sulphuric acids; Optical investigation of mixtures of —. K. Schaefer and H. Niggemann. Z. anorg. Chem., 1916, 98, 77—85. J. Chem. Soc., 1917, 112, ii, 186.

THE absorption limit of 0.2-N nitric acid is displaced towards the ultra-violet even by 20% sulphuric acid, the absorption curve being flattened at the same time, and this effect increases with increasing concentration of sulphuric acid. The sulphuric acid is considered to act as a dehydrating agent, displacing the equilibrium between the two modifications of the NO₃ group.

Lead sulphate; Solubility of — in highly concentrated and fuming sulphuric acid. H. Ditz and F. Kanhäuser. Z. anorg. Chem., 1916, 98, 128—140. J. Chem. Soc., 1917, 112, ii, 208—209.

THE solubility of lead sulphate in highly concentrated sulphuric acid, as in the manufacture of the acid by the contact process, is greater than appears in the literature. The solubility increases with the concentration of the sulphuric acid, slowly up to 97%, then rapidly up to 100%, a discontinuity observed between 98.6% and 98.9% being possibly due to experimental error. From the maximum solubility at 100%, the curve falls to about 5% of free sulphur trioxide, where there is a minimum.

after which it again rises rapidly to 15% of trioxide, and then less rapidly to 22%. The known curve of electrical conductivity of sulphuric acid is very similar to the curve just described. The degree of attack of highly concentrated sulphuric acid on metallic lead also corresponds in general with the same curve.

Basic calcium salt [nitrate]; Synthesis of a — on the ground of a change of properties of milk of lime. N. Busvold. Z. anorg. Chem., 1916, 98, 202. J. Chem. Soc., 1917, 112, ii, 207.

THE power of milk of lime to resist settling is increased by the addition of calcium nitrate, a maximum value for the permanence being found at the composition 2CaO.Ca(NO₃)₂. By slaking quicklime with a concentrated solution of calcium nitrate, white needles of the salt 2Ca(OH)₂.Ca(NO₃)₂.2H₂O, are obtained, which become turbid on the addition of water.

Potassium salts; Utilisation of the mother liquors of sea salt works as a source of —. II. Composition of the mother liquors. III. The bromine and potassium salts industry at Salin de Giroud. E. Manzella. Annali Chim. Appl., 1917, 7, 123—132; 133—141. (See also this J., 1917, 453.)

THE discordant analyses of the mother liquors from salt works are attributable to the different concentrations of the liquids. Analyses by Lacroix of the mother liquors from the salt pans at Salin de Giroud gave the following results:—MgCl₂, 260; NaCl, 34; KCl, 11; MgSO₄, 82; and NaBr, 4 grms. per litre. The composition is thus very similar to that of the mother liquors obtained in the extraction of carnallite and potassium chloride in the Stassfurt works (viz. MgCl₂, 270; NaCl, 38; KCl, 45; and MgSO₄, 36). A sample of the mother liquors from the Trapani sea salt works had sp. gr. 1.278 at 15° C. (=31.4 B.), and contained:—NaBr, 3.07; NaCl, 111.91; KCl, 29.72; MgCl₂, 116.17; MgSO₄, 162.24; and CaSO₄, 1.28 grms. per litre. According to the average results of the analyses of different chemists, mother liquors of 30 B. (sp. gr. 1.262) contain 13.40 grms. of potassium per litre (=25.55 grms. of potassium chloride). The approximate quantities of bromine and potassium chloride which might be obtained annually from the Italian sea-salt works are estimated at 10,775 quintals and 136,386 quintals respectively. If this source of bromine were fully utilised the amount produced by the 32 Italian salt works would be four times as much as that imported into Italy in 1913—1914.

The mother liquors concentrated by the spontaneous evaporation of sea water to 31 B. (sp. gr. 1.271) form the raw material for the extraction of potassium chloride and bromine in the salt works of Salin-de-Giroud, S. France. The mother liquors are concentrated to 34 B. (sp. gr. 1.308) in a series of tanks and separated from the deposit of "mixed salt" (sodium chloride and magnesium sulphate). Formerly this was used for the manufacture of sodium sulphate, but this salt is now obtained more economically as a by-product in other industries. The mother liquors are next conveyed to four large communicating brick-work reservoirs, with outlets for the discharge of the deposits of magnesium sulphate, and are allowed to remain there during the winter. When the temperature falls to 12° C. magnesium sulphate is deposited, whilst to prevent the liquid cooling below that point, when "carnallite" would also be deposited, the surface is covered with a layer of soft water from the Rhone. The following spring the layer of mother liquor, which will then have a density of 32 to 33 B. (sp. gr. 1.285—1.296), is ready for the extraction of the bromine. This is effected by pumping the mother liquors into vessels each of which has a capacity of 20

ch. m., and from these they descend in a regulated stream into stone rectifying columns. At the base of these they meet a current of chlorine derived from connected cylinders of liquid chlorine, and also encounter a jet of steam at a pressure of about 2 atmos. The liberated bromine passes through the successive compartments of the column to the top, and thence is conducted through an inclined U-tube into a condensing coil. The condensed bromine and water are separated by gravity, and the bromine water is returned to the column, whilst the crude bromine is transferred to another vessel where it is heated with steam. The chlorine and part of the vaporised bromine are condensed in another vessel. The greater part of the condensed bromine is collected in bottles, whilst the mixture of uncondensed bromine and chlorine remains in the column. Three separate apparatus are used, each of which is capable of dealing with 50 to 60 cb.m. of mother liquors in 21 hours and yields about 160 kilos. of bromine. About 41 tons of bromine containing only about 1% of chlorine is thus obtained from 15,000 cb.m. of mother liquors. After removal of the bromine the mother liquors, which have a density of about 30 B. (sp. gr. 1.262) at 65 to 70 °C., escape from the bottom of the column and are pumped into Porion evaporators where they are concentrated to 35–36 B. (sp. gr. 1.320–1.332) at a temperature not exceeding 80 to 82 °C. On leaving these tanks they have the following mean composition:—NaCl, 51.80; MgCl₂, 31.68; MgSO₄, 76.50; and KCl, 51.24 grms. per litre. They are now mixed with an equal volume of the solution of magnesium chloride obtained as a secondary product in the further operation of precipitating the double chloride of potassium and magnesium (artificial carnallite), and the hot mixture is pumped into a tank where it deposits while still hot a large amount of "mixed salt," which is now a waste product. The clear supernatant liquid is transferred to crystallisation vessels in which it is cooled to about 20 °C. by means of cooling coils, and the resulting deposit of carnallite is drawn off by means of buckets and drained in cylindrical vessels with false bottoms. The final mother liquor is concentrated to about 40 B. (sp. gr. 1.384) and is used partly for mixing with the liquors coming from the Porion evaporators, and partly in the manufacture of crystalline magnesium chloride. The carnallite is washed with a limited quantity of water, e.g., 900 litres of soft water and 600 litres of washings of 28 B. (sp. gr. 1.211) from a previous operation to 2700 kilos. of the salt, in cylindrical vessels provided with mechanical agitators. After 4 hours the potassium chloride is allowed to settle, and the mother liquor, which is still rich in potassium chloride, is concentrated in a Porion evaporator for further treatment. The crude potassium chloride is washed in 3-ton lots, for about an hour, with 1 cb.m. of cold soft water, in a cylinder provided with an agitator, and is then transferred to a vessel with a false bottom, where it is drained, and is finally dried in a battery of hydro-extractors. The resulting product contains 72 to 75% of potassium chloride, but may be obtained in purer form by repeating the washing. About 600 tons of 72% potassium chloride is thus obtained annually by the treatment of 15,000 cb.m. of mother liquors of 33 B. (sp. gr. 1.296) in the marine salt works of Salin-de-Giroud.—C. A. M.

Potash from silicate rocks: Extraction of—. 11. W. H. Ross, J. Ind. Eng. Chem., 1917, 9, 167–172. (See this J., 1912, 1077.)

By digesting 1 part of felspar and 1.7 parts of lime with water under a steam pressure of 10 to 15 atmos., about 90% of the potash present is dis-

solved, whilst the residue is suitable for the manufacture of Portland cement clinker. By increasing the pressure to 90 atmos. the felspar is almost completely decomposed, but if the proportion of lime is reduced much below that given above, only partial decomposition of the felspar takes place, even at the increased pressure. The addition of a soluble calcium salt equivalent to the alkalis in the felspar increases the amount of potash recoverable when only a limited proportion of lime is used. Since the dust escaping from cement-works kilns contains free lime, it may be found possible to separate the soluble and insoluble potassium salts by digesting the material with water alone under pressure, leaving a residue suitable for cement manufacture (see this J., 1917, 458). In the absence of lime, felspar is not decomposed when digested with water, even at pressures up to 1450 atmos. Estimating the average amount of potash in felspar at 10%, and that 90% thereof is readily recoverable by the above process, a ton of felspar would yield 214 lb. of caustic potash, worth \$10.70. In the case of the potash recoverable by volatilisation from the cement dust when felspar is substituted for clay in the manufacture of cement, it is estimated that the value of the potash recovered as potassium salts would be \$6.75. Assuming the cost of burning 1 ton of lime to be about \$1.00, the expense involved in the addition of the proper proportion of lime to felspar would be about \$1.70 per ton of felspar, so that the difference in the value of the potash recoverable by the two methods would be \$2.25. The potash in felspar is always accompanied by a certain amount of soda. This would depreciate the commercial value of the caustic potash recovered, but would not affect its value for the manufacture of concentrated fertilisers (see also this J., 1912, 531; 1917, 397).—C. A. M.

Calcium carbonate: Rôle of inorganic agencies in the deposition of—. J. Johnston and E. D. Williamson, J. Geology, 1916, 24, 719–750. J. Chem. Soc., 1917, 112, ii, 213. (See also this J., 1916, 688, 735.)

THE authors discuss the effects producible by variation of certain factors which affect directly the solubility of calcium carbonate, and thus induce its precipitation from aqueous solution. The factors concerned are the partial pressure of the carbon dioxide in the atmosphere, the temperature and the concentration of the solution in respect of calcium. At a given temperature, the equilibrium between calcite and its saturated solutions is determined by the coefficient of solubility of carbon dioxide, the ionic solubility product, $[Ca^{++}][CO_3^{--}]$, the ionisation-coefficients of carbonic acid, and the coefficient of hydrolysis of calcium carbonate. The free and the total carbonic acid, that is to say, $[H_2CO_3] + [CO_2^*] + [HCO_3^-]$, determine the degree of alkalinity or acidity of the solution as measured by $[OH^-]$, and no change can be made in any one of the quantities without affecting each of the others. At 16 °C., the solubility of calcite increases from 44 to 75 parts per million, when the partial pressure of the carbon dioxide increases from 0.0001 to 0.0005. Under atmospheric conditions for which the mean value of the partial pressure may be taken as 0.00032, the solubility decreases from 81 parts per million at 0° to 52 parts at 30° C. A change in the partial pressure from 0.00032 to 0.00030, or an increase of temperature of 2° C., would result ultimately in the precipitation of about 2 grms. of calcite from every cubic metre of a solution saturated with it. Comparison of the calculated solubilities with the available analytical data indicates that the warmer surface layers of the sea are substantially saturated with respect to calcite, and precipitation is consequently

to be anticipated if there is a reduction in the partial pressure of the atmospheric carbon dioxide or a rise in temperature of the surface layers in question. Although aragonite is occasionally formed in nature, it is considered that pure aragonite cannot persist in contact with sea-water for any length of time. If, however, the aragonite takes up other substances in the form of a solid solution, and its solubility is thereby reduced below that of calcite, it is possible that such impure aragonite may be stable in contact with sea-water. The accurate determination of temperature, salinity, and free and combined carbonic acid in sea-water in a systematic way would have an important bearing on many outstanding biological and geological problems.

Carbonates of calcium, strontium, barium, and magnesium: Temperatures of formation and decomposition of the — under a pressure of one atmosphere. J. A. Hedvall. Z. anorg. Chem., 1916, **98**, 47—56. J. Chem. Soc., 1917, **112**, ii., 208.

DISSOCIATION temperatures may be determined more rapidly by taking heating and cooling curves than by measurements of pressure. Calcium carbonate gives a well-marked arrest on heating, but the contraction on formation of lime makes the mass so little reactive that the cooling curve is continuous. On increasing the surface of the lime by grinding, however, the absorption of carbon dioxide is hastened, and a corresponding arrest is found on the cooling curve. The dissociation temperature of calcium carbonate is thus found to be 913° — 923° C., this being independent of the size of grain. The dissociation of strontium carbonate begins at 1141° C., but only becomes rapid at 1255° C. Barium carbonate only begins to dissociate at 1361° C., its melting point. Magnesium carbonate dissociates at 516° C.

Carbon dioxide and titanium dioxide and silica respectively: Equilibria between — in alkali, lime-alkali, and alkali-aluminate fusions. P. Niggli. Z. anorg. Chem., 1916, **98**, 241—326. J. Chem. Soc., 1917, **112**, ii., 211—212. (Compare this J., 1913, 1107.)

For the investigation of the system $K_2O-TiO_2-CO_2$, pure titanium dioxide was added to potassium carbonate in a platinum crucible in a continuous stream of carbon dioxide. After equilibrium had been reached, the crucible was quenched and allowed to cool in a desiccator in an atmosphere free from carbon dioxide. Under similar conditions, less carbon dioxide was expelled by titanium dioxide than by silica. The solid phase formed is $K_2Ti_2O_5$, the reaction beginning in the solid state, but only becoming rapid at about 860° C. Carbon dioxide is absorbed on cooling, so that equilibrium may be reached from both directions. Treatment with hydrochloric acid leaves only titanium dioxide, in the form of transparent pseudomorphs after the titanate. In the molten mass other titanates, probably K_2TiO_3 , are formed. In the system $Na_2O-TiO_2-CO_2$, the solid titanate readily separates from the fusion, and there is also loss of sodium carbonate by volatilisation. Carbon dioxide is also frequently evolved during solidification. The principal solid phase is $4Na_2O \cdot 5TiO_2 = Na_8Ti_5O_{11}$, but a titanate, $Na_2Ti_2O_7$, is also formed, as well as Na_2TiO_3 at high temperatures. $Na_8Ti_5O_{11}$ crystallises in forms resembling angite; its refractive index is more than 1.74. The silicates and titanates obtainable from fusions are comparable with hydrated salts, silica and titanium dioxide playing a part similar to water of crystallisation. In the system $Na_2CO_3-CaCO_3$, the double salt, $Na_2CO_3 \cdot CaCO_3$, forms large crystals, m.p. 813° C. Mixtures containing more than 50 mols. % of calcium carbonate deposit calcite as the second solid phase.

The eutectic point between the double salt and the solid solution rich in sodium carbonate is at 786° C. and 40 mols. % $CaCO_3$, the solid solution curve passing through a maximum at about 870° C. The eutectic point in the system $K_2CO_3-CaCO_3$ is at 755° C. and 40 mols. % $CaCO_3$, the solid solution curve being without a maximum. The compound $K_2CO_3 \cdot CaCO_3$ melts at 812° C., and closely resembles the sodium compound. In the system $K_2O-CaO-TiO_2-CO_2$, fusions containing an excess of calcium carbonate convert the whole of the added titanium dioxide into perovskite $CaTiO_3$. Any excess of titanium above this proportion forms $K_2Ti_2O_5$. The corresponding sodium system is quite similar. The product when silica is added to potassium and calcium carbonates is the orthosilicate, Ca_2SiO_4 , and when wollastonite, $CaSiO_3$, is added to the carbonate fusion it is converted into the orthosilicate, Ca_2SiO_4 , and $CaCO_3$ may occur together as solid phases from the same fusion at about 850° C. under atmospheric pressure in carbon dioxide. When alumina is present, silica first acts on the carbonate as if alumina were absent, but the silicate then reacts with alumina, so that an alkali aluminosilicate crystallises, and the liberated alkali then recombines with carbon dioxide. With potassium carbonate, potash-nepheline, $K_2O \cdot Al_2O_3 \cdot 2SiO_2$, is the product from all fusions. Orthoclase is decomposed by alkali carbonate, forming potash-nepheline, the silica thus liberated forming alkali silicate. A ternary diagram for the system $K_2O-Al_2O_3-SiO_2$ is given.

Silica: Reactivity of — with the oxides of calcium, barium, and magnesium in the solid state. J. A. Hedvall. Z. anorg. Chem., 1916, **98**, 57—69. J. Chem. Soc., 1917, **112**, ii., 205.

THE reactions between these oxides have been investigated by means of heating and cooling curves. Lime and precipitated silica react at 1011° C., but the reaction comes to a standstill owing to the formation of a layer of metasilicate. A more vigorous reaction begins shortly above 1400° C., owing to the eutectic temperature of the lime-silica system being reached. The reactivity of other varieties of silica diminishes in the order: silica glass, cristobalite, quartz. Calcium carbonate is acted on to a small extent by precipitated silica at or below 900° C., possibly owing to the presence of a larger proportion of small particles, but the lime formed at the dissociation temperature is not specially reactive. Precipitated silica reacts with barium oxide at 900° C., whilst no arrest has been observed on the heating curve of a mixture of silica and magnesia.

Sodium tetraborate: Water content of crystalline —. J. Hoffmann. Chem. Ind., 1916, **39**, 411—412. J. Chem. Soc., 1917, **112**, ii., 206.

ESTIMATION of the loss of water of crystallisation of sodium tetraborate at different temperatures has shown that the first five molecules begin to be lost below 100° C., whilst six molecules are lost at 100° C.; the seventh and eighth molecules escape at 130° C., the ninth at 150° C., whilst the tenth is evolved at 160° C. and above. At the ordinary temperature crystalline borax has the formula $Na_2B_4O_7 \cdot 10H_2O$; at 100° C., $Na_2B_4O_7 \cdot 5H_2O$; at 130° C., $Na_2B_4O_7 \cdot 3H_2O$; at 150° C., $Na_2B_4O_7 \cdot 2H_2O$; at 180° C., $Na_2B_4O_7 \cdot H_2O$. The penultimate molecule of water of crystallisation is retained more firmly than the others, and prolonged heating is necessary to remove it. Borax of the composition, $Na_2B_4O_7 \cdot H_2O$, exists in traces far above this temperature, but below 318° C. the bulk of the water is driven off. When it is desired to obtain practically anhydrous borax in the non-glassy form, the crystalline material is heated at 318° C. (m.p. of potassium nitrate). Absolutely anhydrous borax is difficult to obtain in the non-glassy

state, since the dehydrated powder absorbs water more readily than the glassy material. The latter during five months only absorbs 0.1% of water, whilst this amount is absorbed by the former in twenty-four hours. After sixteen months the powdered form had absorbed 10, the glassy 0.6, molecules of water.

Barium sulphate: Effect of adsorption on the physical character of precipitated —. H. B. Weiser. *J. Phys. Chem.*, 1917, **21**, 311—333.

IN accordance with the general principle that a solid salt shows a distinct preferential adsorption for its own ions, the barium ion is always present in barium sulphate precipitates, even when produced in solutions containing an excess of soluble sulphate. An important effect is exerted by adsorption on the state of division of the precipitate; barium sulphate is precipitated in the most finely divided state when in presence of those substances for which it shows the greatest specific adsorption. By mixing $N/10$ barium chloride with a small excess of $N/10$ sodium sulphate in solution containing one part of water to five of glycerol, a fairly stable colloidal suspension of barium sulphate resulted, which owed its stability to preferential adsorption of the sulphate ion. By examining the direction of migration in an electric field, the colloid was seen to be negatively charged. Positive colloidal solutions of barium sulphate stabilised by preferential adsorption of the barium ion have been previously prepared. It was found that barium sulphate is obtained much more finely divided when precipitated from a solution with barium chloride in excess than with sulphuric acid in excess. Precipitates produced with potassium sulphate are also more finely divided than with sulphuric acid. This is due to the fact that barium sulphate adsorbs its own ions strongly and hydrogen ions are more strongly adsorbed than most cations. With excess of sulphuric acid, the strong adsorption of the sulphate ion is checked by the presence of the hydrogen ion, whereas with potassium sulphate the adsorbed sulphate ion is not so completely neutralised. By substituting magnesium for potassium sulphate, the precipitate obtained appeared somewhat less finely divided, as would be expected from the fact that divalent ions are adsorbed more strongly than univalent ones. The effect of the presence of hydrochloric acid on the crystal size was studied both in the presence of barium and of sulphate ions in excess. In all cases the barium sulphate was more coarsely crystalline when precipitated in the presence of an appreciable amount of hydrochloric acid. With barium chloride in excess and in presence of hydrochloric acid, the strong adsorption of both hydrogen and barium ions and the relatively weak adsorption of chlorine would be expected to cause a finer crystalline structure, but here the adsorption effects are overcome by the larger influence exerted by the solvent action of the acid, on account of which large crystals are always obtained in presence of an excess of hydrochloric acid. With the same concentration of hydrochloric acid, the precipitate is more crystalline in the presence of sulphate ions in excess than with barium ions in excess, as the tendencies for adsorption of sulphate and hydrogen ions are mutually opposed.—J. N. P.

Uranium oxide (UO_2): Preparation of black —. C. L. Parsons. *J. Ind. Eng. Chem.*, 1917, **9**, 166—167.

URANYL chloride when heated with a reducing agent in a fused salt bath yields uranium oxide, and the reaction may be utilised in practice by

fusing sodium uranate with carbon in a salt bath. Based upon this principle, a purer uranium oxide than has hitherto been prepared industrially is now being made in ton lots in the National Radium Institute, U.S.A., by the following method:—A mixture of 35 parts of salt, 20 parts of sodium uranate, and 1 part of ground charcoal is heated in a cast steel pot of pure low carbon steel, 19 in. deep, by 16 in. wide, with wall $\frac{1}{4}$ in. thick. The pot is heated by means of an oil burner in a crucible furnace, and its contents are not stirred during the reaction, but as the charge subsides a fresh quantity of the mixture is added from time to time. Reaction takes place at a red heat and is allowed to continue until no more carbon monoxide escapes from the mass. The resulting oxide is then dipped from the bottom of the pot, by means of an iron ladle, and transferred together with the salt melt to an iron trough. About 1 charge per day can be worked in each furnace, and the steel pot will take from 35 to 40 charges before being destroyed by the heat. After cooling, the salt mass is broken up and treated with boiling water, and the uranium oxide is washed by decantation. As a rule it contains some iron and aluminium, but, if necessary, these can be extracted by washing the oxide with 5% hydrochloric acid. In commercial practice, however, no attempt is made to separate the whole of the iron, as its presence is not objectionable in the manufacture of ferro-uranium, and a product with a degree of purity equivalent to 97% U_3O_8 is usually obtained. Sodium uranate made from carnotite always contains a certain amount of vanadium. In the process described, the sodium vanadate dissolves with the salt and the vanadium may be separated by precipitation with iron sulphate. The value of the recovered vanadium will pay for about half of the whole process. The average cost of producing the black oxide of uranium is slightly less than 11 cents per lb., but it could be reduced by running the furnace continuously. —C. A. M.

Zirconyl bromides. E. Chauvenet. *Comptes rend.*, 1917, **164**, 816—818.

ON evaporating on a water bath a solution of zirconium hydroxide, $Zr(OH)_4$, in hydrobromic acid, needle-shaped crystals separate, which, on drying in a current of air at 15° C. until of constant weight, correspond to the formula, $ZrOBr_2 \cdot 8H_2O$. This compound is readily soluble in water, and if entirely free from hydrobromic acid is non-hygroscopic, but in presence of retained acid it absorbs water, whilst in dry air, or *in vacuo*, water is given up with the formation of $2ZrOBr_2 \cdot 7H_2O$, which is the lowest hydrate of zirconyl bromide. The anhydrous bromide does not appear capable of existence. On heating the above hydrate to over 60—70° C., decomposition takes place in accordance with the equation:—

The oxybromide is also precipitated from a $N/100$ solution of zirconyl bromide on standing for several months. By following the variation of electrical conductivity, hydrolysis of the bromide was found to take place in accordance with the equation:—

A hydrate of the complex oxybromide of the formula, $ZrOBr_2 \cdot ZrO_2 \cdot 12H_2O$, was isolated by adding ether to an alcoholic solution of zirconyl bromide. The oxybromide, on heating to redness or in a current of dry hydrogen bromide, decomposes into zirconium bromide and oxide:—

—J. N. P.

Osmium dioxide. O. Ruff and H. Rathsburg. Ber., 1917, 50, 484—497.

WHEN osmium dioxide is obtained by reduction of osmium tetroxide or potassium osmate, or by hydrolysis of ammonium hexachloro-osmate, it is always pyrophoric, in the sense that it decomposes very readily in air, with considerable evolution of heat or even with detonation. The decomposition appears to be due to the presence of compounds containing carbon and hydrogen or nitrogen and hydrogen. A stable preparation may be obtained by the hydrolysis of potassium hexachloro-osmate. This product contains a little alkali, but is free from reducing substances. Pure osmium dioxide can only be obtained in the crystalline form by heating the finely divided pure metal in osmium tetroxide vapour. The precipitated dioxide is colloidal and has the composition, $\text{OsO}_2 \cdot 2\text{H}_2\text{O}$. It readily forms sols in water which is slightly acid or alkaline, or free from neutral electrolytes. On heating in an indifferent gas (carbon dioxide or nitrogen) half of the water is lost below 120°C . and the remainder below 200°C . The anhydrous dioxide thus prepared has sp. gr. 7.71. On further heating to 400°C . the change of density proceeds along with a progressive change of colour. The original dihydrate is bluish black and the final product distinctly brown. At about 460°C . decomposition into osmium tetroxide and metallic osmium begins to be evident, but this change can be delayed to about 650°C . by heating in an atmosphere containing osmium tetroxide. Under these circumstances the dioxide is finally converted into copper coloured octohedral and hexahedral crystals of sp. gr. 7.91.—W. H. P.

Carbon suboxide: Preparation of — from malonic acid and phosphorus pentoxide. A. Stock and H. Stoltzenberg. Ber., 1917, 50, 498—502. (See also this J., 1906, 500; 1907, 169; 1908, 182, 1133.)

THE authors have improved the method of preparing carbon suboxide (C_3O_2) by taking precautions to avoid excessive polymerisation of the suboxide in presence of phosphorus pentoxide, and opportunity for the suboxide to react with acetic acid which is produced along with carbon dioxide by decomposition of the malonic acid. From 20 grms. of malonic acid they obtained 968 c.c. of suboxide containing only 0.7 c.c. of carbon dioxide. The melting point of the suboxide is -111.3°C . and its vapour pressure at 0°C . 59 cm. Polymerisation to the red solid is an autocatalytic reaction, depending on the nature of the surface of the containing vessel, independent of the action of light, accelerated by phosphorus pentoxide, and retarded by diminution of pressure or dilution with carbon dioxide. The suboxide dissolves readily in carbon bisulphide and in xylene, and reacts quantitatively with water giving malonic acid.—W. H. P.

Oxy-hydrogen gas: Ignition point of —. A. Mitscherlich. Z. anorg. Chem., 1916, 93, 145—166. J. Chem. Soc., 1917, 112, ii., 199.

DRY oxy-hydrogen gas, prepared electrolytically, was passed through a tube heated by means of a large, gas-heated copper tube, the temperature being measured by quartz-mercury thermometers reading up to 650°C . When highly diluted with inert gas, no noise of explosion was perceptible, but the ignition point could be fixed by the appearance of a flash in a darkened room, even when the action was insufficient to cause any perceptible movement of the mercury in the manometer. The ignition temperature was higher, the lower the velocity of the gas in passing through the tube, when the velocity was low. At higher velocities, the temperature was independent of the

velocity. The formation of water took place below the ignition point, to an extent which varied with the condition and previous treatment of the glass tube. In silica tubes there was a still greater formation of water below the ignition temperature, whilst very little was formed in tubes of glazed, and especially unglazed, porcelain which had been previously heated for a long time at 700°C .

Fluorine; Preparation of — from hydrogen fluoride or other fluorides by chemical means. O. Ruff, W. Plato, and G. Winterfeld. Z. anorg. Chem., 1916, 98, 27—37. J. Chem. Soc., 1917, 112, ii., 201—202.

BRÄUNER (Chem. Soc. Trans., 1891, 65, 393) claims to have prepared fluorine by heating the double salt, $3\text{KF} \cdot \text{HF} \cdot \text{PbF}_4$ (compare following abstract). This result has not been confirmed, the products of decomposition by heat being lead difluoride and platinum tetrafluoride when a platinum vessel is used. Liquid or gaseous silicon tetrafluoride is practically without action on the double salt, a small quantity of gas acting on potassium iodide-starch paper being obtained at 250°C . but without altering the composition of the salt. A larger quantity is obtained by the use of antimony pentafluoride. Sulphur and iodine form sulphur fluoride and iodine pentafluoride respectively. Triammonium hydrogen plumbodifluoride, $3\text{NH}_4\text{F} \cdot \text{HF} \cdot \text{PbF}_4$, was prepared by dissolving lead tetra-acetate in concentrated hydrofluoric acid and adding ammonium hydrogen fluoride, filtering, and evaporating. The salt may be heated at 190°C . under atmospheric pressure or even under 10 mm. pressure without change, but in a good vacuum decomposition takes place at 100°C . nitrogen being evolved.

Fluorine: Preparation of — from tripotassium hydrogen plumbodifluoride by chemical means. B. Brauner. Z. anorg. Chem., 1916, 98, 38—46. J. Chem. Soc., 1917, 112, ii., 202. (Compare preceding abstract.)

THE differences between the results obtained by the author in 1894 and those of Ruff are not explained. The earlier lead preparation contained manganese, which may have acted as a catalyst, or the gas evolved by heating may not have been fluorine. It is, however, shown that silicon does not inflame spontaneously in dry hydrogen fluoride.

PATENTS.

Acids or other liquids: Concentration or recovery of —. L. J. R. Bouhon. London, Eng. Pat. 105,935, Feb. 21, 1916. (Appl. No. 2579 of 1916.)

THE apparatus comprises an evaporating chamber containing a series of plates inclined to the horizontal and having a corrugated or dimpled surface, over which the acid or other liquid is caused to flow evenly. Connected with this evaporating chamber is a furnace for heating air which is supplied under pressure, and is forced through a series of heating tubes before passing on to the evaporating chamber. A condensing chamber completes the apparatus, and here the

moisture carried away by the heated air is cooled and condensed. The air supply can be regulated as required.—J. B. C. K.

Sulphuric acid; Manufacture of — in tower systems. F. Curtius and Co., Duisburg, Ger. Pat. 295,708, July 17, 1911.

THE arrangement of towers is shown in the diagram. Two methods of working are described:—(a) Tower 8 is sprinkled with acid from the Glover tower, and the product,

together with the acid from the other towers, is conveyed to tower 1 where it is denitrated. Some of the denitrated acid is removed and the rest is brought back to 8. Acid flows between 2 and 7, 3 and 6, 4 and 5, in both directions. (b) Tower 8 receives the Glover acid, and the product is conveyed to 7, 2, 1 in succession, the acid from the other towers also passing to 1, where the whole is denitrated. Towers 3 and 6, and 4 and 5, work in a closed circuit.—E. H. T.

Sulphuric acid; Manufacture of —. [Removal of hydrogen sulphide from coal gas.] B. Krizko, Lupény, Hungary. Ger. Pat. 295,709, Mar. 31, 1915.

HYDROGEN sulphide, or a gas containing it, is passed into copper sulphate solution, and the precipitated copper sulphide is mixed with an excess of copper oxide and heated in air, whereby it is reconverted into sulphate. The latter is extracted with water, and the residual oxide used again. The method is especially suitable for eliminating hydrogen sulphide from the gases obtained in the destructive distillation of coal.

—E. H. T.

Sulphuric acid; Manufacture of —. B. Dirks, Hemelingen, Ger. Pat. 295,906, Dec. 12, 1915.

AMMONIUM sulphate, prepared by the action of ammonia and carbon dioxide gases on gypsum or anhydrite, is decomposed with phosphoric acid, the resulting sulphuric acid being free from arsenic and selenium. The residual ammonium phosphate is decomposed by heat and the ammonia and phosphoric acid recovered.—E. H. T.

Sulphur dioxide; Furnace for making —. J. Pintsch A.-G., Berlin. Ger. Pat. 295,747, Jan. 7, 1915.

A VESSEL, shaped like a filter-funnel is fitted into a cylindrical oven divided laterally into two parts, the cone of the funnel being in the upper, and the stem in the lower compartment. The sulphur is melted in the conical part, which is surrounded by a hot oil-jacket, and falls on to the hearth of the lower compartment where it is burnt, the gases which enter the upper part serving to keep the sulphur melted. There is an exit pipe in each compartment, and by regulating the draught the sulphur can be maintained at the requisite temperature.—E. H. T.

Gases (ammonia); Purification of —. W. T. Gidden, Smethwick. Eng. Pat. 105,826, June 12, 1916. (Appl. No. 8301 of 1916.)

AN impure but substantially homogeneous gas, e.g., ammonia, is bubbled through a quantity of the same gas which has been liquefied. The liquefied gas collects the impurities and may be

allowed to evaporate so as to assist the purifying action by the cold produced, or it may be prevented from evaporating by the application of cold or pressure.—W. H. C.

Metallic sulphides; [Electrolytic] production of —. C. O. Griffith, Wormit, Fife. Eng. Pat. 105,830, June 28, 1916. (Appl. No. 9087 of 1916.)

ZINC, antimony, or other metallic sulphide is prepared by electrolysing a solution of ammonium or other suitable chloride, using an anode and cathode of the same metal (zinc, antimony, etc.), the cathode being coated entirely or in part with sulphur.—B. N.

Aluminium carbide; Art of producing —. M. Barnett and L. Burgess, New York. U.S. Pat. 1,222,593, Apr. 17, 1917. Date of appl., Jan. 26, 1917.

A MIXTURE of about 2 parts of alumina with 1 part of carbon, the latter being in excess of the quantity necessary for the reduction of the alumina, is packed around a core of carbon or graphite through which is passed an electric current sufficient to raise the temperature to about 2000° C., but not to that of the electric arc.—B. V. S.

Aluminium salts from silica's; Method of obtaining —. R. H. McKee, Orono, Me. U.S. Pat. 1,222,960, Apr. 17, 1917. Date of appl., Mar. 13, 1916.

SILICATES such as sericite are roasted with lime or limestone and a chloride, and the resulting mass extracted with water to remove the soluble potassium salts. The residual silicate is decomposed by an acid reagent.—B. V. S.

Oxygen compounds of nitrogen; Production of — from ammonia. N. Busvold, Rjukan, Norway. U.S. Pat. 1,222,928, Apr. 17, 1917. Date of appl., Dec. 16, 1915.

A GASEOUS mixture containing oxygen and ammonia is passed over a suitable catalyst in such a way that the pressure of the issuing mixture is lower than that of the atmosphere; the drop of pressure in the catalyst is not more than 50 mm. of mercury.—B. V. S.

Oxides of uranium; Process for preparing —. Process for the purifying of uranium compounds. C. L. Parsons, Durham, N.H. U.S. Pats. (A) 1,221,013 and (B) 1,221,014, Apr. 24, 1917. Date of appl., May 19, 1915. (Dedicated to the public.)

(A) A MIXTURE of a uranium compound, such as a uranate, a flux, and a reducing agent, such as carbon, is fused and the resulting mass washed with an alkali solution, water, and an acid. (B) Alkali uranates may be purified by fusion with a flux, such as a chloride, incapable of forming a soluble compound with the uranium, and washing the residue. Vanadium and similar impurities are removed (see also page 644).—B. V. S.

Bisulphite liquor; Apparatus for making —. G. A. Stebbins, Watertown, N.Y. U.S. Pat. 1,221,578, May 1, 1917. Date of appl., Aug. 31, 1915.

THE apparatus comprises absorption and agitating compartments, an overflow receptacle provided with a constant level device in communication with the lower portion of the agitating compartment, and a cooling coil discharging into the upper portion of the absorption compartment. Gas is supplied to the lower end of the absorption compartment and is withdrawn from the upper end and delivered to the lower part of the agitating compartment. A basic solution is supplied to the upper part of the agitating compartment. Means are provided for elevating monosulphite liquor from the constant-level receptacle to the cooling

coil, and agitating means within the agitating compartment, and between the gas inlet and the inlet for the basic solution.—J. B. C. K.

Chromates; Manufacturing metallic——. K. Toabe, Winchester, Mass. U.S. Pat. 1,225,374, May 8, 1917. Date of appl., Oct. 6, 1916.

A METAL, such as lead, is subjected at a selected temperature, 60° to 140° C., to the action of a solution containing water, chromic acid, and an acid, such as nitric acid, which has a solvent action on the metal.—B. N.

Percarbonate; Manufacturing alkali-metal——. A. Schaidhauf, Frankfort, Germany, Assignor to Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,225,722, May 8, 1917. Date of appl., Jan. 16, 1917.

SODIUM percarbonate is produced by mixing hydrogen peroxide with sodium carbonate, previously roasted to destroy detrimental catalysts. The mixing operation is done in the presence of a magnesium alkali silicate, and gum arabic is added to the product of the reaction.—B. N.

Electrolysis [of alkali chlorides]; Device for—— with a mercury cathode. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 295,800, Apr. 12, 1914.

To prevent alkali amalgam rising to the surface of the brine, and the accompanying increase of resistance, two diaphragms are placed between the anode and the mercury, the upper one supporting the mercury.—E. H. T.

Sodium thiosulphate [e.g., residues from manufacture of sulphur dyes]; Process of obtaining sodium sulphate and sulphur from——. Act.-Ges. f. Anilinfabr. Ger. Pat. 295,859, Apr. 25, 1914.

THE thiosulphate is decomposed by treatment with warm sulphuric acid, or with the equivalent amount of an acid salt of a di- or poly-basic acid, in particular with a bisulphate. The reaction proceeds quantitatively, and can be used for working up the residues from the manufacture of sulphur dyes.—E. H. T.

Zinc oxide containing lead, lead sulphate, carbonate, etc.; Partial or complete removal of lead from——. S. E. Goldschmidt und Sohn, Breslau. Ger. Pat. 295,921, Feb. 20, 1914.

THE oxide, freed from carbonate by ignition, is treated with zinc sulphate, the lead sulphate is extracted with a solution of sodium or potassium acetate, and the solution treated with barium sulphide. In this way both lead and sulphuric acid are completely removed, and the alkali acetate solution may be used again.—E. H. T.

Tungsten carbide; Production of pieces of—— of any desired size or shape. Voigtländer und Lohmann, Metallfabrikations-Ges. m.b. H., Essen. Ger. Pat. 295,726, May 17, 1914. Addition to Ger. Pat. 289,066 (this J., 1916, 423).

In order to prevent the carbide becoming crystalline, a small amount of molybdenic oxide or carbide, or metallic molybdenum, is added before the second heating takes place.—E. H. T.

Sulphuric acid; Manufacture of——. W. H. Waggaman, Washington, D.C., U.S.A. Eng. Pat. 101,408, Aug. 14, 1916. (Appl. No. 11,482 of 1916.) Under Int. Conv., Sept. 4, 1915.

SEE U.S. Pat. 1,185,029 of 1916; this J., 1916, 736.

Concentrating acids; Method and apparatus for——. T. C. Oliver, Charlotte, N.C., U.S.A. Eng. Pat. 105,993, May 11, 1916. (Appl. No. 6743 of 1916.)

SEE U.S. Pat. 1,195,075 of 1916; this J., 1916, 1015.

Ammonia; Catalytic production of——. C. Bosch and A. Mittasch, Assignors to Badische Anilin und Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,225,755, May 15, 1917. Date of appl., Nov. 18, 1911.

SEE Fr. Pat. 436,472 of 1911; this J., 1912, 432.

Titanic products; Manufacture of——. H. Wade, London. From The Titanium Alloy Manufacturing Co., New York. Eng. Pat. 105,853, Aug. 14, 1916. (Appl. No. 11,492 of 1916.)

VIII.—GLASS; CERAMICS.

Glasses for protecting the eyes from injurious radiations. W. W. Coblentz and W. B. Emerson. U.S. Bureau of Standards, Techn. Paper No. 93. J. Franklin Inst., 1917, 183, 629.

BLACK, amber, green, greenish-yellow, and red glasses efficiently protect the eyes from ultra-violet light. White glass affords some protection from the extreme ultra-violet rays from mercury-quartz lamps and from electric arcs between iron, copper, or carbon. For shielding the eyes from infra-red rays, deep black, yellowish-green, gold-plated, sage-green, and bluish-green glasses are efficient, the two last being preferable for furnace work. Of the infra-red rays emitted by a furnace at 1100° C., about 90% are obstructed by gold-plated glasses, 95% by sage- or blue-green glasses, 80% by very deep black glasses, and 60% by greenish-yellow glasses. For working with oxy-acetylene or in electric welding, it is important to wear the darkest glasses available.—A. B. S.

Refractory materials; Deterioration of—— in the iron and steel industries. H. B. Croushaw. Trans. Faraday Soc., 1917, 12, 153—165.

THE chief cause of the deterioration of bricks in open-hearth furnaces is the combination of basic flue-dust and volatilised oxides with the material of the bricks. The intensity of the bombardment by dust particles is greatest in the centre of the roof and least in the middle of the furnace. The slag formed by the action of the dust on the bricks forming the roof seems unable to penetrate them, so that permeability and porosity are not so serious as is often supposed. It has a better opportunity of penetrating the bricks forming the lower part of the walls. The "cutting action" of flames, the rapid movements due to sudden changes in temperature, and particles of slag shot up from the molten charge also assist in the destruction of the bricks. The deterioration of regenerator bricks is mainly of a chemical nature, due to the fluxing action of the basic dust derived from the charges and slag, and carried over from the body of the furnace.

The deterioration of the bricks used in lining blast furnaces and cupolas varies with their position. Near the top of the furnace the chief

cause is the abrasion due to fresh charges of ore and fuel, but within the shaft the brickwork is largely replaced by a black porous "scar" of graphite. At the hearth, chemical action between the contents of the furnace and the bricks is the chief cause of the destruction of the latter. Bricks free from iron oxide, and the exercise of care to prevent the formation of this oxide, are recommended. Deterioration by dust may be partially prevented by keeping the amount of dust produced (especially when charging) as low as possible, by suppressing the dust before it reaches the regenerators, and possibly by using neutral or basic bricks made of bauxite, serpentine, steatite, limestone, dolomite, and magnesian limestone, though the application of these materials opens up a wide field of research. To resist destruction in blast-furnaces and cupolas, the composition and texture of the bricks must be adjusted, and bricks used which are free from iron oxide. Abrasion is only important in blast-furnaces and cupolas, and in these it is increased by the formation of a friable scar and by careless charging. Differential movements tend to general disintegration and open up cracks and joints into which corrosive slags and vapours may penetrate. Other factors concerned are workmanship, regulation of temperature, adjustment of the-rods, variation in shape and size of fire-bricks, and the use of damaged bricks.

—A. B. S.

Refractory materials used in the iron and steel industries: Standardisation of—H. B. Cross-shaw. Trans. Faraday Soc., 1917, 12, 166—169.

STANDARD specifications for any particular industry must state to what furnaces and portions of furnaces the tests apply, and before limits can be set the chemical and physical conditions prevailing in each part of every furnace typical of the industry must have received full investigation. The following suggestions are merely tentative:—*Mineral composition* should be determined by means of analysis and microscopical examination of thin sections. *Texture* should be described in terms of precise form, size, and manner of aggregation of the particles. *Uniformity of shape and size* should be kept within specified limits. *Position marks* should be used to prevent errors in laying the bricks. The *soffening point* should be determined under strictly specified conditions. *Permeability* should be determined by partially immersing a cube of the material in molten slag and then comparing its porosity with that of an untreated sample; the nature of the penetration should be studied in micro-sections. *Resistance to sudden changes in temperature* should be tested by raising the sample to a definite temperature, cooling rapidly under stated conditions, and then determining the crushing strength. *Dilatation* is measured by measuring a sample when cold and then at a prescribed high temperature. (No method has yet been devised for this.) *Permanent expansion and contraction* should be measured as in the Institution of Gas Engineers' specification (this J., 1912, 612). *Hardness* is determined by an abrasion test. *Crushing strength* tests are useful in conjunction with other tests.—A. B. S.

Reactivity of silica with the oxides of calcium, barium, and strontium in the solid state, Hedvall. See VII.

PATENTS.

[Glass] *insulator*. F. M. Locke, Victor, N.Y. U.S. Pat. 1,225,147, May 8, 1917. Date of appl., Sept. 1, 1914.

A HEAT-RESISTING glass of low coefficient of expansion (not more than 0.000005) is formed by fusing

together relatively large amounts of silicic material with a boron compound, cryolite, and a small amount of an alkali.—B. N.

Glass furnace: Regenerative—C. Menzel, Lommatzsch. Ger. Pat. 295,933, June 15, 1916. Addition to Ger. Pat. 289,827 (this J., 1916, 424).

THE roof of the furnace chamber is provided with projecting ribs, whereby the heating gases passing from the inlets on one side to the outlets on the other acquire a rotary motion, which promotes their action upon the glass mass.—C. A. M.

Saggars. W. L. Aynsley and G. Reynolds, Longton, Staffs. Eng. Pat. 105,995, May 12, 1916. (Appl. No. 6796 of 1916.)

IN a cylindrical saggur for firing earthenware in a Dressler tunnel kiln, the sides and bottom are perforated to admit the hot gases to the earthenware, and the upper edge may also be indented. The base may be perforated to receive the lowest thimble-supporting members for the ware. In a rectangular saggur the sides, ends, and base are perforated, and the sides may be lower than the ends so that the saggars may be placed one above the other, leaving longitudinal slots. The upper edges of the side walls may be grooved longitudinally to receive the thimble supports. The base of the saggur is provided with a longitudinal knife-edge support.—W. F. F.

Brick-kiln and method of operating the same. C. E. Vredenburg, Mechanicsville, N.Y., and T. Lacey, Quincy, Mass. U.S. Pat. 1,224,243, May 1, 1917. Date of appl., Feb. 19, 1915.

A FORCED draught of air is supplied to the zone of fuel between the heads of the kiln and passes downward through the fuel. An independent forced draught is supplied laterally to the fuel beneath the head or heads, and the two draughts of air are prevented from mixing.—W. F. F.

Kiln for and method of treating ceramic and similar material. J. T. Underwood and I. M. Justice, Dayton, Ohio, Assignors to Underwood Engineering Co., Detroit, Mich. U.S. Pat. 1,224,978, May 8, 1917. Date of appl., Apr. 17, 1916.

GAS and air are forced into the top of a kiln and are there burned. The outlet flue in the sole is restricted, so that the pressure inside the kiln is greater than that outside and incoming draughts of cold air are prevented. (See Reissue of U.S. Pat. 1,105,724; this J., 1917, 310.)—A. B. S.

Tunnel kiln. C. Dressler, Marlow, England. U.S. Pat. 1,225,318, May 8, 1917. Date of appl., May 21, 1916.

A MODIFICATION of Eng. Pats. 18,114 and 28,617 of 1910 (this J., 1911, 1251) in which a series of sleeves, each with gas- and air-burners, is provided for heating the combustion chambers at several points, in addition to the burner at one end of each chamber.—A. B. S.

Earthenware and the like: Cranks or frames for supporting—during firing. W. L. Aynsley and G. Reynolds, Longton, Staffs. Eng. Pat. 106,145, May 17, 1916. (Appl. No. 7021 of 1916.)

Apparatus for drying sand and the like. U.S. Pat. 1,224,132. See 1.

Tunnel muffle furnaces for burning ceramic ware and heating metals, chemicals, and other materials. Ger. Pat. 295,987. See 1.

IX.—BUILDING MATERIALS.

Cement drain tiles [pipes] and concrete in alkali soils; Durability of —. R. J. Wig, G. M. Williams, A. N. Fimm, S. H. McCrory, E. C. Bebb, and L. R. Ferguson. U.S. Bureau of Standards, Tech. Paper No. 95. J. Franklin Inst., 1917, 183, 625—628.

THE use of concrete has proved unsatisfactory in some of the arid regions of the United States in which the soil contains free alkalis. It is concluded that in such situations only a dense concrete, made with not less than 1 part of Portland cement to 3 parts of aggregate and with a minimum amount of water to give a "quaking" consistency, should be used. Porous concrete is liable to disintegration resulting from the expansion of crystalline salts absorbed by the concrete from the soil. Apparently, the greater the quantity of sulphate and magnesium present and the greater the total concentration of salts, the greater will be the disintegration. The cores should not be removed until several hours have elapsed after casting. Machine-made pipes are more resistant than hand-made ones. Steam curing is not better than sprinkling with water. Sand-cement is not so good as Portland cement. A tar-coating and cement grouting do not prevent the absorption of alkalis from the soil. The addition of ferrous sulphate confers no advantage.—A. B. S.

PATENTS.

White hydraulic cement and polish salts; Process of making —. C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,224,454, May 1, 1917. Date of appl., June 29, 1911.

A MIXTURE of a silicate mineral containing potassium with a calcareous substance is heated to a temperature below the volatilising point of the potassium compounds, and the heated mixture is quenched in calcium chloride solution. The product in a subdivided condition is rapidly heated to a clinkering temperature, thus forming a cement clinker, and volatilising the potassium salt, which is separated from the gases.—W. F. F.

Cement mortar [and concrete]; Process of mixing —. M. T. Hochstrasser, Gainesville, Fla. U.S. Pat. 1,225,129, May 8, 1917. Date of appl., July 25, 1916.

FINELY ground cement is sifted into an excess of water to form a colloidal mass. The excess of water is drained off, and the residue is then mixed with the coarser ingredients of the concrete or mortar.—A. B. S.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Ferromanganese in the iron and steel industry. R. J. Anderson. J. Franklin Inst., 1917, 183, 579—592.

IN a statistical review of the industries concerned,

particulars are given of the chief sources of manganese ore and the production of ferro-alloys. The uses of manganese in the metallurgy of iron and steel are described and reference is made to the more limited employment of other deoxidants (aluminium, ferrosilicon, ferrotitanium, etc.) in metallurgy, and also to the use of molten ferro-manganese in the manufacture of special steels. Practically no organised effort to find a substitute for manganese in the iron and steel industry has been made hitherto, and to this end the co-operation of manufacturers and research chemists is now urged.—W. E. F. P.

Steel; Torsional hysteresis of mild —. J. J. Guest and F. C. Lea. Proc. Roy. Soc., 1917, A.93, 313—332.

THE angular strain produced in bars of steel when subjected to a varying torsional force was measured by the displacement of a beam of light reflected from two mirrors attached at a definite distance apart along the bar. For any given value of the torque, the slope of the stress-strain curve, and thus the modulus of rigidity, was found to depend upon the way the stress is changing; at any given stress, including zero stress, it is not a constant quantity but depends on the previous history of the material. Hysteresis loops given by the stress-strain curves on cyclical variation of the load were found to exist at stresses considerably below the accepted elastic limits for mild steel; they increase with the range of loading. By allowing bars which had been overstrained to rest for several days, the width of the hysteresis loop was reduced, and heating to 100° C. had also a marked effect in extending the range in which the hysteresis loop is narrow. This is in accordance with the observation that the elastic limit in compression of cold-drawn steel tubes is raised by tempering at temperatures from 300° to 550° C. Steel in which a condition of overstrain has been produced, e.g., by cutting machinery, may be normalised gradually by a considerable period of rest or rapidly by slight heat treatment. Since fatigue effects depend on the gradual increase of the width of the hysteresis loop with repetition, it would appear that tempering at comparatively low temperatures removes initial stresses and thus considerably increases the resistance of the steel to repetition stress.—J. N. P.

Steel; Embrittling action of sodium hydroxide on mild —, and its possible relation to seam failures of boiler plates. P. D. Merica. Met. and Chem. Eng., 1917, 16, 496—503.

FAILURES at the seams of boiler plates have been traced to the action by alkali on the steel and the effect has been found to be analogous to the brittleness produced during the "pickling" of steel in dilute acids, or when the metal is exposed as cathode during electrolysis. In all these cases, nascent hydrogen is generated on the surface of the metal and diminishes the toughness of the steel. While at ordinary temperatures iron is passive or non-reactive to hydroxide solutions at concentrations between $N/10$ and $2N$, if the concentration of the hydroxide is increased, the passivity disappears and a reaction of the form: $\text{Fe} + x\text{OH} = \text{FeO}_x + x\text{H}$, becomes possible. With $2N$ sodium hydroxide, iron assumes a potential of about 0.2 volt, and with $16N$ sodium hydroxide this increases to about 1.2 volt, at which the formation of hydrogen becomes possible. At higher temperatures, the reaction is more rapid, hydrogen being generated by the action of $N/1$ sodium hydroxide on steel at 150°—200° C. Measurements were made of the tensile strength, and resistance to impact and alternating stress, on samples of steel after exposure in closed

iron vessels to a solution of 13·6N sodium hydroxide, for intervals varying from 5 to 30 days, at temperatures of 100°, 180°, and 280° C. The steel used was in the form of annealed wire of $\frac{1}{4}$ in. diam. and contained C 0·18, P 0·024, S 0·015, and Mn 0·42%. The degree of chemical action was indicated by the pressure of hydrogen generated. The results of the tensile tests showed no effect of the sodium hydroxide on the yield point or on the ultimate strength, and the lowering of elongation was generally within the limits of experimental error. A marked embrittling effect of the sodium hydroxide was shown by the results of the repeated bending test, the number of alternations of stress withstood after treatment at 180° and 280° C. being on an average about 20% lower than the value for untreated metal. The influence of time of treatment showed that the brittleness increased up to about one week, and then decreased, the steel recovering its original mechanical properties either partially or wholly. This effect may be due to the hydrogen liberated during the first period of the action of the alkali, before the oxide is formed by corrosion, being given up in the nascent state and absorbed by the iron, while later the hydrogen formed by the anodic solution of the iron is evolved at the cathode, which is now the electro-negative oxide and can come in contact with the iron itself only by secondary diffusion or after it has assumed the molecular state. After the embrittling action of the alkali has ceased, the metal gradually returns to its original condition through continued exposure to heat, which enables the hydrogen to diffuse out of the material, as in the case of iron which has been "pickled" in acid and which loses the acquired brittleness by subsequently heating for a short time to 100° C. It was found that at a higher temperature the alkali reacts more quickly and to a greater degree than at lower temperatures. With more concentrated alkali, the action was increased; with N/10 alkali at 200° C. no effect on the tensile properties was observed, though there was noticeable corrosion. Samples exposed while under tension in a steel frame showed slightly less tendency to become brittle by the action of alkali. Apart from the view that the action of alkali on the physical properties of steel is due to absorption of nascent hydrogen, the action has been attributed to a penetration of the alkali into the metal, causing an eating away of the amorphous intercrystalline material, which is the first to be attacked. It has also been suggested that sodium hydroxide causes a crystallisation or coalescence of the smaller crystals into larger ones. According to either of these theories, which do not account for the gradual recovery of the original mechanical properties, the brittleness would be similar to that produced by burning or overheating, whereas no increase in grain size was observed as a result of treatment with alkali. Measurements of potential showed that after treatment with concentrated alkali at 100° C. and above, the E.M.F. of samples of steel in contact with dilute sodium hydroxide, was considerably higher than that of the original metal, and by turning off from 0·015 to 0·30 in. from the surface of the metal before measuring, it was found that the effect extends into the specimen for a considerable distance, and that this increase of potential is also produced by immersion for a few minutes in dilute acids or by cathodic polarisation. The embrittling effect of alkali can be prevented, as would be expected from the theory of hydrogen occlusion, by adding an oxidising agent such as sodium bichromate to the solution. Potential measurements showed this action to be one of depolarisation, and the E.M.F. between iron and concentrated solutions of sodium hydroxide was considerably lowered by the

addition of bichromate. The corrosion of samples of steel by alkali was also found to be considerably diminished and of a different character in presence of bichromate. With sodium hydroxide alone, the surface became rough and covered with a porous, loose deposit of black Fe_2O_3 , while with the addition of sodium bichromate, the surface was smooth and covered with a thin, firmly adherent coating of brown Fe_2O_3 . The corrosion of boilers which occurs at the seams and tube caps has been particularly observed in cases where the feed water contains appreciable amounts of sodium carbonate. By dissociation of the carbonate and escape of the carbon dioxide, sodium hydroxide is left and becomes concentrated in the seams by enclosure and leakage outwards. Moreover as the passivity of iron in alkali at low concentrations is diminished by the presence of chlorides, corrosion may take place at low hydroxyl concentrations. Sodium carbonate is also frequently present as a constituent of boiler compounds. Samples of boiler scale or incrustation which ooze through at the seams have been found to contain from 1 to 5% of sodium hydroxide. The remedy against the corrosion in question would appear to consist in the elimination from boiler water of alkali, which can be precipitated by adding ferrous or magnesium sulphate. Sodium chromate, which inhibits the action of the alkali, might also be advantageously added to alkaline water.—J. N. P.

Iron and boron. N. Tschischewsky and A. Herdt. *Rev. Soc. russe Mét.*, 1915, 1, 533—546. *Rev. Mét.*, 1917, 14, Extr., 24—26.

IRON-BORON alloys containing up to 11·54% B were prepared from pure Swedish iron and ferroboron, and their cooling curves determined. For micrographic examination the specimens were cooled slowly and etched with a solution of sodium picrate. The eutectic alloys presented the appearance of pearlite ("boron-pearlite") to a greater degree than the corresponding carbon steels. At 0·08% B continuous masses of ferrite were exhibited, surrounded by thin lines of pearlite; the latter gradually widened and extended as the boron content increased, until the eutectic composition and the maximum of pearlite were reached at 3·1% B. At 3·5% B the formation of prismatic boride crystals ("boron-cementite") commenced; these increased with the boron content and finally agglomerated into masses separated by veins of eutectic. Polished sections of alloys containing more than 8% B were prepared only with difficulty, owing to general brittleness and lack of cohesion. The 8·85% alloy consisted of a mass of long prismatic crystals of the composition Fe_2B . The results of the chemical, thermal, and micrographic analyses are shown in a diagram.—W. E. F. P.

Iron-boron-nickel alloys [boron-nickel steels]. N. P. Tschischewsky and S. Mikhailovsky. *Rev. Soc. russe Mét.*, 1915, 1, 547—559. *Rev. Mét.*, 1917, 14, Extr., 16—21.

THE effect of boron upon iron is similar to that of carbon as regards progressive hardening, but more intense; the hardness is accompanied by great brittleness. In seeking to produce ternary alloys which, while retaining the hardness of the iron-boron series, would also possess sufficient tenacity for commercial requirements, nickel was employed as the alloying metal. From pure Swedish iron (C 0·1%), ferroboron (B 19·56, C 0·17%), and pure nickel, ten series of alloys were prepared containing (1) C 0·05—2·27%, B and Ni none; (2) B 0·0—4·32%, Ni none; (3) B 0·0—4·41, Ni 4·7—5·0%; (4) B 0·0—1·21, Ni 10·0—10·7%; (5) B 0·0—0·78, Ni 0—20%; (6) B 0·73—1·04, Ni 0—22%; (7) B 1·21—1·42, Ni 0—25%; (8) B 2·17—2·76,

Ni 0.0—19.81%; (9) B 3.15—3.90, Ni 0—25%; and (10) B 4.24—4.41, Ni 0—10%. Diagrams are given showing the Brinell hardness of the alloys as a function of the boron and nickel content, respectively. In the absence of nickel the hardness increases with the boron content up to 2%, then decreases as the boron is increased to 2.4%, and again increases between 2.4 and 4.32% B. The effect of nickel is to increase the hardness still more, without changing the general form of the curves. Under the pneumatic hammer, only the alloys of highest boron content were brittle when hot. Up to 4.32% B the alloys were still forgeable at red heat; but at 2% B the alloys were brittle in the cold state. The fragility of the iron-boron alloys in the cold was increased by the addition of nickel; but with increasing nickel the alloys became more forgeable owing to the lowering of the forging temperature. The brittleness of the alloys in the cold state is attributed to the presence of a fusible eutectic which increases in proportion with the nickel content; the authors are of opinion that the forgeable alloys will find practical applications by reason of their extreme hardness.

—W. E. F. P.

Cyanide solutions; Solvent power of — [for gold].

H. R. Edmonds. Monthly Jnl. Chamber of Mines of W. Australia, 1916, 143. J. Chem. Met. Soc. S. Africa, 1917, 17, 160.

THE solvent action of zinc sodium cyanide solution on strips of gold in the absence of free lime was found to be only 5—6% of that of sodium cyanide solution of nearly equivalent strength (0.14% KCN). The retarding effect of free lime increased with its concentration, and with about 0.07% of CaO, sodium cyanide was almost without action after 16 hours' agitation, while zinc sodium cyanide dissolved a very small amount of gold. Thiosulphates did not affect the solvent power adversely, but were reduced in contact with zinc dust, with formation of zinc sulphide. Thio-cyanates were not thus reduced.—W. R. S.

Manganese-gold alloys. L. Hahn and S. Kyropoulos. Z. anorg. Chem., 1916, 95, 105. Rev. Mét., 1917, 14, Extr., 27—30.

THE manganese employed in the preparation of the alloys was obtained by the aluminothermic reaction and contained Mn 91.7, Al 5.3, Fe 0.7, Si 0.5, and Cu 0.4%. The curve showing the solidifying points of the alloys has a distinct maximum at 50 atomic % Au, and two minima at 32½ and 77½ atomic % Au. The alloys were grey in colour up to 62.5, but yellow between 75 and 87.5 atoms % Au; all were homogeneous in structure. Dendritic and polyhedral crystallites were present in those containing up to and above 50 atoms % Au, respectively. The dimensions of the latter form increased with the percentage of gold; the manganese content of the dendritic crystallites decreased from the centre towards the periphery. The velocity of diffusion of gold in manganese appeared to be very slow. The alloys were very brittle at about 55, difficultly forgeable between 55 and 62.5, and easily forgeable above 62.5 atoms % Au. Specimens were exposed to the action of hydrochloric acid for periods up to 1157 hrs., and the losses of manganese and gold determined. The results were in general agreement with Tamman's theory of solubility (Z. anorg. Chem., 1914, 90, 297).—W. E. F. P.

"Nichrome"; Analysis of cast —. E. W. Reid. J. Ind. Eng. Chem., 1917, 9, 488—490.

FOR the analysis of cast nichrome, which usually

contains Ni 58—62, Fe 23—26, Cr 8—14, Mn, Zn, and Si 0.5—2.0, and C 0.2—1.0%, the following method is submitted as affording satisfactory results:—*Silicon.* 2.5 gms. of the alloy (turnings) is dissolved in *aqua regia* (6HCl:1HNO₃) and two evaporations to dryness are made to render silica insoluble. The ignited residue is treated with hydrochloric and a little nitric acid, the liquid diluted and filtered, and the "silica insoluble" ignited and weighed. As the latter usually contains particles of undissolved metal and oxides, the silica is removed, and the silicon determined, by two evaporations with hydrofluoric and sulphuric acids; the final residue is boiled with hydrochloric acid, any insoluble matter being fused with sodium peroxide and the melt dissolved in hydrochloric acid. The combined acid solutions are diluted to 500 c.c. and aliquot portions used for subsequent determinations. *Nickel.* The volumetric cyanide process is preferred as being more rapid and accurate than the dimethylglyoxime method in the presence of iron, manganese, chromium, zinc, vanadium, and tungsten. In this process the slightly ammoniacal nickel solution, containing a known amount of silver iodide in suspension and to which excess of tartaric or citric acid has been previously added to prevent precipitation of iron, etc., is titrated first with a standard solution of potassium cyanide (containing free alkali) until the silver iodide is completely dissolved, and then back with standard silver nitrate until a faint opalescence is obtained; the method is an adaptation of Moore's process described in Sutton's "Volumetric Analysis," 9th Ed., 1904, p. 251. *Iron, chromium, and zinc.* The first two constituents are precipitated together by ammonia in the presence of ammonium chloride in excess, the precipitate being filtered off and the filtrate set aside for the determination of zinc. *Iron.* The precipitate is dissolved in hydrochloric acid and the solution made strongly alkaline with sodium or potassium hydroxide, when excess of bromine water is added and the liquid boiled and filtered. The iron precipitate is next re-dissolved in hydrochloric acid and re-precipitated as before, then re-dissolved in hydrochloric acid and re-precipitated by ammonia, and finally re-dissolved in sulphuric acid and the solution reduced with zinc and titrated with standard potassium permanganate. *Chromium.* The combined filtrates from the iron precipitation are acidified with sulphuric acid and cooled to 20° C.; excess of manganous sulphate is then added, followed by excess of standard ferrous ammonium sulphate and titration with standard permanganate. *Zinc.* The filtrate from the iron-chromium precipitation is evaporated nearly to dryness, treated with concentrated nitric acid and evaporated to about half bulk, when excess of potassium chlorate is added and the liquid boiled, diluted, and filtered through a Gooch crucible. The solution is then neutralised with ammonia and heated to boiling, when a slight excess of dimethylglyoxime solution is added and the nickel precipitate removed, the filtrate being subsequently acidified with hydrochloric acid, heated to 70°—80° C., and titrated with standard potassium ferrocyanide. *Manganese.* An aliquot portion of the acid solution is evaporated almost to dryness, treated with nitric acid, and evaporated to about half bulk, when excess of potassium chlorate is added, the liquid evaporated to small volume, and a second addition of chlorate made to complete the precipitation of manganese. The liquid is then diluted and filtered through asbestos, the precipitate being dissolved in excess of standard ferrous ammonium sulphate and the solution titrated back with standard permanganate. *Carbon* is determined by direct combustion in a current of oxygen or by the method described in Blair's "Chemical Analysis of Iron and Steel," 7th Ed., 1912, p. 134.—W. E. F. P.

Phosphorus: Determination of— in zinc phosphide. G. Libéri. *Annali Chim. Appl.*, 1917, 7, 144—151.

THE zinc phosphide is decomposed with dilute sulphuric acid, and the liberated hydrogen phosphide is absorbed in a solution of silver nitrate. The resulting precipitate is decomposed when the liquid is diluted with water: $(\text{PAg}_3 \cdot 3\text{AgNO}_3) + 3\text{H}_2\text{O} = 6\text{Ag} + 3\text{HNO}_3 + \text{H}_3\text{PO}_3$. The decomposition flask is fitted with a funnel provided with a stop cock, and communicates with an absorption tube with 8 to 10 bulbs, followed by a Peligot tube, and with a Kipp apparatus, from which a current of dry carbon dioxide can be admitted. The air is first displaced by this gas, 0.2 to 0.3 grm. of the zinc phosphide introduced, the gas again passed through the apparatus, and about 20 c.c. of water and 50 c.c. of dilute sulphuric acid admitted through the funnel. Reaction takes place in the cold, but it is necessary finally to heat the flask gently for about 30 mins., the slow current of carbon dioxide being meanwhile continued. The contents of the absorption vessels are then transferred to a beaker, and the tubes washed out first with nitric acid and then with water. The silver is precipitated from the solution by means of hydrochloric acid in slight excess, the liquid filtered, and the phosphoric acid in the filtrate precipitated in the usual way and weighed as magnesium pyrophosphate. The weight of the precipitate multiplied by 0.2787 gives the quantity of phosphorus in the zinc phosphide.—C. A. M.

Tin-cadmium and tin-bismuth alloys: Constitution of—. A. Bucher. *Z. anorg. Chem.*, 1916, 98, 97—127. *J. Chem. Soc.*, 1917, 112, ii., 211.

SMOOTH rods were obtained by melting the alloys *in vacuo*, forcing them up into an evacuated glass tube, and subsequently breaking away the glass. The electrical conductivity and its temperature-coefficient, and the thermo-electric force were determined on the rods, silver being used as comparison metal. The results showed that tin and cadmium are reciprocally soluble to the extent of 3% in the solid state, the conductivity and thermo-electric curves being straight between those limits. The solubility of tin in solid cadmium diminishes with falling temperature. These results were in accord with the micro-structure of the alloys. Tin will hold up to 14% of bismuth, and bismuth up to 1.5% of tin in solid solution. The conductivity temperature-coefficient and the thermo-electric curves of the tin-bismuth alloys show strongly marked discontinuities at the eutectic composition. This appears to be connected with the micro-structure, alloys on the tin side of the eutectic point being fine-grained, whilst those containing free bismuth have a very coarse structure.

Ore flotation: Theory of—. H. P. Corliss and C. L. Perkins. *J. Ind. Eng. Chem.*, 1917, 9, 481—488.

FROM a consideration of practical and theoretical data it is concluded that, to be capable of flotation, an ore particle must pass to the interface between oil and water, or completely enter the oil phase. In the absence of oil the particle must pass to the interface between water and air, but the force holding the particle to the bubble is much greater when oil is present. In addition to its value as a lifting agent, the bubble serves to produce a large air surface in contact with the pulp, and as this surface is covered to a greater or less extent by an oil film, a small amount of oil is very efficient. The emulsification of the oil should be sufficient to last during the actual flotation period in pneumatic processes, but should in no case be so com-

plete as to prevent the transference of oil to the bubble surface. The harmful effect of certain colloids and so-called "flotation poisons" is due to their property of causing too stable an emulsion, or of being adsorbed on the oil film at the bubble surface and thus preventing mineral attachment. The froth formed is attributable to the soluble portion of the flotation mixture, which produces a variable surface tension, or to finely divided or colloidal materials. All the above factors are affected more or less by the presence of acids, alkalis, and salts, but with the exception of colloidal charges, electrical effects are not important in flotation. All solids possess the inherent property of adhering to oil or water to a certain degree, and under the conditions of flotation treatment these forces tend to come to equilibrium with the interfacial tension between oil and water at some definite contact angle. If the substance is smooth and shiny (e.g., polished metal or newly fractured sulphide crystal) the liquid first touching it is easily pushed back to the equilibrium position when brought to the interface with another liquid, but if the substance has a dull (i.e., capillary) surface, so that the liquid first wetting it is strongly held in its pores, no interfacial properties may be exhibited although the same material might show even a preference for the second liquid if the particles were smooth.

—W. E. F. P.

Blast furnaces: Air drying for—. L. Canamen. *Proc. Eng. Soc. W. Pa.*, 1917, 33, 199—204.

A 30% SOLUTION of calcium chloride neither gains nor loses water in contact with air at the ordinary temperature, but becomes very hygroscopic when cooled to -9°C . Air is dried by passing it, in counter-current, through the calcium chloride solution maintained at the proper temperature. Having become diluted through absorption of moisture, the brine is concentrated in evaporators and passed through cooling coils, when it is again ready for use. The process is continuous, requires little labour, and obviates the high temperature required for dehydrating the salt. The cost of the necessary machinery is estimated at one-quarter of that required for the dry-cold process.—W. R. S.

Lead blast-furnace slags: Treatment and utilisation of—. F. von Schlippenbach. *Metall u. Erz*, 1916, 13, 437. *Chem.-Zeit.*, 1917, 41, Rep., 78.

THE molten slag is allowed to stand, and to cool partially, in large vessels, whereby matte and lead settle to the bottom or adhere to the walls, the inner liquid slag only being removed. By this means about one-half of the lead and silver contents can be saved. The slag is not suitable for granulation as its sulphur content prevents its use for builder's sand or for concrete buildings; it may, however, be used for the manufacture of slag bricks, or, if broken up, for concrete foundations and for road-making. It is possible that it would pay to recover zinc oxide from it.—E. H. T.

PATENTS.

Steel ingots: Casting of — W. G. Armstrong, Whitworth, and Co., Ltd., and H. H. Ashdown, Newcastle-on-Tyne. Eng. Pat. 105,617, Apr. 20, 1916. (Appl. No. 5802 of 1916.)

INGOTS of large size such as for use in the manufacture of guns and marine forgings, which may weigh 100 tons or more, are cast in a mould having a cooling medium circulating in its walls in such a manner that the sides of the ingot are quickly cooled and the segregation of non-metallic material in the main body of the ingot is prevented. The mould is provided in its walls with pipes through which the cooling medium, such as air or water, is circulated, the piping being divided into independently controlled sections. The metal is admitted by a feeding head of usual construction and generally the sides of the ingot are first cooled and then the metal is cooled from its base upwards. In some cases, especially when very large ingots are being cast, the operation takes a considerable time and the upper portion of the mould becomes hot before the level of the metal reaches it, and it may be desirable to cool this portion of the mould early in the operation. An increase of the life of the mould is also secured by this system of inside cooling, which avoids the heavy stresses otherwise developed by the great differences of temperature between the inside and outside faces of the mould.—J. N. P.

Steel ingots: Manufacture of — G. A. Wilson, Middlesbrough. Eng. Pat. 105,875, Nov. 29, 1916. (Appl. No. 17,119 of 1916.)

To prevent the formation of cavities in the upper part of steel ingots when cast in moulds, the top surface is covered with blast-furnace or other slag wool. A heavy cover of iron plate or brick is used to give a downward pressure and to prevent loss of heat. The top surface of the ingot has a concave depression when solid.—W. F. F.

Steel: Manufacture of — F. D. Carney and L. B. Lindemuth, Bethlehem, Pa. U.S. Pat. 1,223,030, Apr. 17, 1917. Date of appl., Nov. 20, 1916.

BESSEMERISED metal is charged into a basic open-hearth furnace together with sufficient manganese-bearing material to produce a slag of which the manganese content is sufficiently high to cause a portion of the manganese to enter the metal of the bath beneath it. The slag should contain at least 10% and the metal at least 0.15% Mn.—W. H. P.

Metallic coatings: Process for making — by means of a compressed gaseous medium. G. Stolle, Kiel, Germany. Eng. Pat. 12,719, May 23, 1914. Addition to Eng. Pat. 23,289 of 1913, dated Oct. 21, 1912 (this J., 1917, 294).

As an improvement on the original process, in which partly or wholly volatilised metal is blown against the articles in the open, the present addition has for its object the lowering of the vaporising temperature of the coating metal, by the use of a vacuum chamber, so that inflammable or similar articles may be coated without injury. The metal vapour from the volatilising chamber is drawn through a suction nozzle which acts as an ejector and is operated by compressed gas. A partial vacuum is thus formed in the chamber, while the volatilised metal particles are cooled by the gaseous current before impinging on the article under treatment.—W. E. F. P.

Aluminium or aluminium alloys: Coating of — with other metals. Clement Talbot, Ltd., and P. E. Kneil, London. Eng. Pat. 105,971, May 3, 1916. (Appl. No. 6362 of 1916.)

ALUMINIUM articles are heated and cleaned by

abrasion while hot, and the surface is coated with an aluminium solder. A less corrodible metal such as tin is then rubbed on to the coating of solder while still hot. The method is particularly applicable for lining bearings with white metal such as Babbitt metal, the white metal being run in, in the usual way, after coating with solder. A suitable solder consists of tin 81%, zinc 14.58%, aluminium 3.61%, and commercial phosphor tin 0.78%.—W. F. F.

Metals [iron]: Vapour treatment of — [by zinc]. Machine for continuous treatment of metals.

(A) W. A. Darrah and S. Trood, Wilkesburg, (B) S. Trood, New Castle, Pa., Assignors to Industrial Development Co. U.S. Pats. (A) 1,224,339 and (B) 1,224,340, May 1, 1917. Dates of appl., Apr. 4 and June 16, 1914.

(A) THE metal (iron) is heated in the presence of the metal vapour (zinc) under reduced pressure in a chamber from which other gases and vapours have been previously exhausted. (B) The heating chamber of the apparatus is provided with a seal of the liquid coating metal and with a trap for preventing loss of the latter. The seal is designed to control the passage of vapour to and from the chamber and to withstand the pressure of the atmosphere when the chamber is exhausted.

—W. E. F. P.

Tempering metal: Process and apparatus for forming and — The Rockefeller Motor Co., Cleveland, Ohio, Assignees of T. J. Fay, Brooklyn, N.Y., U.S.A. Eng. Pat. 101,142, Apr. 26, 1916. (Appl. No. 6000 of 1916.) Under Int. Conv., Aug. 11, 1915.

THE apparatus is particularly suitable for tempering steel plates in the manufacture of springs. The steel plate is heated to a temperature just above recalcence, e.g., to 1460° F. (793° C.) to 1535° F. (835° C.), and placed in suitable dies which are resiliently pressed together by counterweights through the medium of springs. The dies are each composed of thin parallel plates having their edges serrated so that the area in contact with the spring plate is minimised, and an adjustable cam may be provided at the ends to impart an additional curvature to the spring. Electrically operated means are provided whereby the spring plate is clamped, lowered while still just above recalcence temperature through two jets of quenching liquid directed longitudinally over the plate toward the centre, and then into a tank containing oil above and water below. The plate is then withdrawn after a predetermined interval which may be varied by varying the distance moved through the liquid or by varying the rate of travel. The surface temperature on withdrawal should be about 100° F. (205° C.) and the final uniform temperature about 850° F. (455° C.).—W. F. F.

Metals: Winning — from sea-water or other natural solutions. O. Nagel, Laussingrande, Austria. Eng. Pat. 103,310, Jan. 12, 1917. (Appl. No. 636 of 1917.) Under Int. Conv., Jan. 8, 1916.

IN obtaining precious metals such as gold, silver, platinum, thorium, radium, or the like, from sea water, by precipitation on adsorbents such as fullers' earth, clay, crushed bricks, light granulated blast furnace slag coated with colloidal ferric hydroxide, colloidal ferric hydroxide, infusorial earth, coal, coke, peat charcoal, wood, etc., the water is first filtered or centrifuged to remove suspended matter. Alternatively the adsorbing mass is cleaned intermittently by back washing, or the two methods may be combined.—W. F. F.

Ores; Concentration of — [by flotation]. H. L. Sulman, E. Edser, and Minerals Separation, Ltd., London, Eng. Pat. 105,627, Apr. 20, 1916. (Appl. No. 5851 of 1916.)

IN an agitation-froth process for the concentration of oxide or carbonate ores, a small regulated quantity of soap is used as the frothing agent. Either the metalliferous particles or those of the gangue are floated in preference according to the nature of the ore, and the particular soap and quantity used. The amount of salts present in the water used, which would bring about precipitation of the soap, must be ascertained, or the liquid should, in the first place, be made slightly alkaline to avoid this decomposition. In cases where both the gangue and metallic particles tend to be floated together, the recovery and concentration of the mineral in the froth can be improved by the addition of hydrocarbon oils, sodium silicate, phosphate, or hydroxide, or silicic acid sol. A hot liquor is in some cases favourable to the separation. —J. N. P.

Ores; Washing and classifying apparatus for —. C. R. Pinette, Chalon-sur-Saône, France, Eng. Pat. 105,690, July 31, 1916. (Appl. No. 10,802 of 1916.)

THE ore is fed on to an inclined screen suspended in a tank filled with water. The screen receives a rapid reciprocating motion, and the coarser particles of ore are delivered from the upper edge, which is above the level of the water, into an outlet passage. The finer particles, falling through the screen, are pushed to the sides of the tank by a right and left-handed screw, and then raised by elevators, working in inclined passage-ways, along with a certain amount of water, to overflow outlets. Several apparatus may be mounted in series, with various sizes of screen. The feeding of water to the first tank then suffices for the whole series.

—W. H. P.

Copper; Obtaining [by electrolysis] of — from its ores. A. A. Lockwood, London, Eng. Pat. 105,772, Jan. 21, 1916. (Appl. No. 1900 of 1916.)

PULPED copper ore passes from a reservoir, where it is kept agitated by an air jet, to an electrolysing vessel containing cathodes consisting of iron plates, and anodes of lead. The iron plates are dipped in boiling tar and covered with powdered graphite which may be coated with copper. Alternatively the copper may be deposited on the tarred plates without the use of graphite. The deposited copper may be removed on warming the plates. (See also Eng. Pat. 22,627 of 1911; this J., 1912, 196.)—W. F. F.

Copper; Hydrometallurgical apparatus for the recovery of —. E. R. Weidlein, Thompson, Nev., Assignor to Metals Research Co., New York, U.S. Pat. 1,223,451, Apr. 21, 1917. Date of appl., Feb. 21, 1916.

COPPER-BEARING material is leached with sulphuric acid and the solution passed into a tall cylindrical tank which is provided with an annular jacket through which heated oil is circulated in order to raise the temperature of the charge. The copper is precipitated by admitting sulphur dioxide under pressure, the precipitated metal is withdrawn at the base of the tank, and the remaining solution circulated continuously with the solution in the leaching tank. —J. N. P.

Copper; Hydrometallurgy of —. J. C. Greenway, Warren, Ariz., and H. W. Morse, Los Angeles, Cal., U.S. Pat. 1,221,458, May 1, 1917. Date of appl., June 5, 1916.

ORE containing copper and iron is treated with sulphuric acid, and copper is precipitated from a

portion of the solution by means of metallic iron. The ferric sulphate in another part of the solution is reduced to ferrous sulphate partly by the action of sulphur dioxide and partly by the action of precipitated copper obtained as above. The precipitated copper is thus dissolved, the solution is acidified, and the copper finally deposited by electrolysis. —W. F. F.

Furnace [; Melting —]. A. C. Ionides, jun., London, Eng. Pat. 105,810, May 11, 1916. (Appl. No. 6757 of 1916.)

IN a melting furnace of the reverberatory hearth type, the material to be melted is fed by the tube, *k*, into the annular crucible, *f*, having a removable cover, *i*, and contained in a casing, *l, j*. A combustible gaseous mixture, distributed according to

the system described in Eng. Pat. 102,983 (this J., 1917, 206), is supplied to tangential inlet nozzles passing through both walls of the ring, *m*, into the crucible. The combustion products leave by the aperture, *x*, space, *o*, and pipe, *b*, and the molten metal is drawn off by the pipe, *h*. In a modification, the pipe, *b*, extends upward into the crucible to provide an additional passage for the gases. —W. F. F.

Calcining furnace [; Electric —]. W. R. Clymer, Lakewood, Ohio, Assignor to National Carbon Co., U.S. Pat. 1,223,475, Apr. 24, 1917. Date of appl., Oct. 16, 1915.

A SHARP furnace, with provision for heating the charge by means of electrodes placed horizontally near the base, is provided with a conveyor consisting of an inclined tube which permits the material to slide slowly into the top of the furnace. The inclined tube is surrounded by an enclosed space through which hot gases from the furnace are passed in order to preheat the charge before admission to the furnace. Heat is also supplied by the combustion of volatile products evolved from the charge in the conveyor, which escape through perforations in the central tube and burn on mixing with air in the surrounding chamber. —J. N. P.

Refractory auriferous ores; Treatment of —. J. H. Niemann, Adelaide, S. Australia, U.S. Pat. 1,222,789, Apr. 17, 1917. Date of appl., July 14, 1913.

THE raw ore is treated in the presence of selenium or a selenium compound with a weak cyanide solution in a non-oxidising atmosphere. The gold is precipitated from the resulting selenocyanide solution in the form of a slime. The slime may be distilled to recover values other than gold, and is finally retorted in a reducing atmosphere. —W. H. P.

Smelting furnace; Oil or gas burning—. O. P. Moore, Spokane, Wash. U.S. Pat. 1,225,470, May 8, 1917. Date of appl., Aug. 2, 1916.

ORE is fed through the opening, 21, into the pre-heating and reduction chamber, 18, the wedge, 34, deflecting it on to the ledges, 35. The rods, 30, are reciprocated at intervals to feed the ore through the opening, 26, into the smelting or refining vessel, 9. Two burner jets, 6, are directed on to the surface of the material. A system of air flues and heating flues surrounds the vessel, 9, so that a draught is produced through the discharge chamber, 17. The air and heating flues are so arranged that a partial upward draught is produced in the pre-heating chamber, 18, when the discharge chamber, 17, is closed.

—W. F. F.

Annealing articles; Method of—. A. L. Pollard, Batavia, N.Y. U.S. Pat. 1,222,793, Apr. 17, 1917. Date of appl., Dec. 1, 1916.

A LAYER of articles to be annealed is placed in an oven covered with a layer of protecting material, and heated till malleable. Another layer of articles and another layer of protecting material is added and the heating continued. The process is continued till the oven is filled, and when the last layer is sufficiently heated the whole mass is allowed to cool slowly.—W. H. P.

Fine ores and flue dust; Agglomeration of—. W. Schumacher, Berlin, Germany, Assignor to General Briquetting Co., New York. U.S. Pat. 1,222,893, Apr. 17, 1917. Date of appl., Jan. 26, 1916.

FINELY divided particles of fine ores of which the sintering and melting points are relatively close together, are formed into round or egg-shaped briquettes, which are exposed to a temperature between the sintering and melting points of the ore. While in the sintering or roasting zone the briquettes are maintained in constant movement.

—W. H. P.

Magnetic objects; Apparatus for testing—. F. P. Fahy, Washington, D.C. U.S. Pat. 1,223,377, Apr. 24, 1917. Date of appl., Sep. 23, 1912.

THE effect of heat treatment (e.g., annealing) on a material is determined by electromagnetically comparing the test-piece with another test-piece of the material, of the same shape, but which is in a thoroughly annealed condition. The two test-pieces are subjected simultaneously to different portions of the flux of a changing magneto-motive force, and the differential of the induction produced is measured.—J. N. P.

Vanadium-bearing ores; Method of treating—. R. S. Davis, Newmire, Colo., Assignor to Primos Chemical Co., Primos, Pa. U.S. Pat. 1,223,567, Apr. 24, 1917. Date of appl., July 28, 1911.

THE ore is subjected to a chloridising roast, the roasted ore is leached with water, and the undissolved residue then leached with a solution prepared by dissolving in water the gases evolved during the roasting. The vanadium is thus recovered as soluble vanadate.—J. N. P.

Zinc and iron; Method of recovering—from solutions thereof. C. E. Baker, Chicago, Ill. U.S. Pat. 1,224,657, Apr. 24, 1917. Date of appl., Jan. 26, 1917.

THE method consists in precipitating the two metals simultaneously in the form of a non-compact deposit, and then effecting a separation by vaporising the zinc.—W. H. P.

Aluminium-calcium alloy and process of making the same. H. S. Cooper, Assignor to The Cooper Co., Cleveland, Ohio. U.S. Pat. 1,224,562, May 1, 1917. Date of appl., Sept. 29, 1916.

FOR use in casting, an alloy of aluminium with not more than 8% of calcium is claimed. The alloy is ductile and specifically lighter than aluminium.

—W. E. F. P.

Nickel and nickel alloy; Flux for welding—. R. Samseutheuer, Assignor to Autogenwerk Sirius, G.m.b.H., Dusseldorf-Eller, Germany. U.S. Pat. 1,224,418, May 1, 1917. Date of appl., Dec. 29, 1914.

THE flux consists of a mixture of "alkali, metal chloride and chromium"; part is applied in the form of a paint to the edges of the weld and to the filling wire, and part is incorporated in the filling wire.—W. E. F. P.

Ores; Method of treating [extracting metals from]—. H. L. Friberger, Eureka, Kans., Assignor to V. C. Joslyn and C. H. Keller, El Paso, Tex. U.S. Pat. 1,224,917, May 8, 1917. Date of appl., June 3, 1916. Renewed Mar. 20, 1917.

FINELY-DIVIDED ore containing precious metals is treated with a solution containing cyanide and an alkali resinate, and subdivided air currents are blown through. Part of the ore is thereby "frothed" and the solution is filtered and treated for the recovery of the precious metals. The treating solution is made by dissolving a resinous substance in alcohol, adding alkali till neutral, distilling off superfluous solvent, and adding cyanide solution.—W. F. F.

Soldering compound. F. E. J. Litot, Wilkinsburg, Pa. U.S. Pat. 1,224,941, May 8, 1917. Date of appl., June 5, 1916.

A SOLDERING alloy contains zinc, tin, and lead, the zinc being in smaller quantity than the tin or lead, to reduce the melting point. As an example, the proportions, zinc 25 parts, tin 45 parts, lead 55 parts, are given.—W. F. F.

Lead sulphide ores; Treatment of—[to produce basic lead sulphate]. P. C. H. West, London. U.S. Pat. 1,225,296, May 8, 1917. Date of appl., Nov. 24, 1915.

POWDERED lead sulphide is fed on to a deep bed of incandescent coke at a temperature below that which would be produced by injecting air, and is volatilised at 1000°–1100° C. at reduced pressure. The vapour is partly oxidised and the oxidation is completed at a lower temperature. Basic lead sulphate is obtained.—W. F. F.

Zinc; Method and apparatus for recovering—from zinc-bearing ore. D. B. Jones, Lake Forest, Ill. U.S.A. Eng. Pat. 106,050, Oct. 25, 1916. (Appl. No. 15,180 of 1916.)

SEE U.S. Pat. 1,213,180 of 1917; this J., 1917, 313.

Sulphating materials [ores]; Method of—. H. B. Hovland, Duluth, Assignee of G. B. Frankforter, Minneapolis, Minn. U.S.A. Eng. Pat. 100,488, May 12, 1916. (Appl. No. 6816 of 1916.) Under Int. Conv., May 15, 1915.

XI.—ELECTRO-CHEMISTRY.

Current-potential lines; Some particular cases of —. A. H. W. Aten, Proc. K. Akad. Wetensch. Amsterdam, 1917, 19, 653—670, 768—778. J. Chem. Soc., 1917, 112, ii., 163, 190—191.

THE form of the curve connecting the electrode potential with the current density is considered and it is shown that the limiting current is proportional to the ion concentration of the solution and to the diffusion-coefficient and inversely proportional to the thickness of the diffusion layer.

These considerations are applied to the electrolysis of solutions containing halogen ions with a silver anode. The most favourable conditions for the separation of halogen in the form of silver halide at the anode with a minimum loss of silver by anodic dissolution, deduced from the theory put forward, are for the most part those which have been found most satisfactory according to the empirical experiments which have been made by various observers. The fact that the accuracy with which the halogens can be estimated by this method increases with increase in the atomic weight of the halogen, is due to the diminishing value of the ionic insolubility product of the corresponding silver halides. The conditions favourable to the formation of insoluble metallic compounds by the anodic dissolution of the metal are also derived and found to agree with those indicated by practice. The author's views are also applied to the electrolysis of solutions of complex salts, the alkali silver cyanide solution being specially considered, and it is shown that the conditions under which silver cyanide is deposited on the anode, thereby increasing the resistance and reducing the current, may be deduced from the theory. To avoid this in practice, the current density must not exceed a certain value, which, of course, depends to some extent on the concentration of the solution.

Electro-reduction of nitrates of potassium and lithium by alternating current. J. Kliatchko and C. Binggely. Ann. Chim. Analyt., 1917, 22, 81—81.

THE authors have electrolysed solutions of potas-

sium and lithium nitrate with alternating current under various conditions to investigate the factors determining the extent to which reduction takes place. Rotation of the electrodes is always accompanied by more reduction. The electrode materials used vary in effect but can be arranged in the following order of reducing power: cadmium, lead, zinc, copper. Aluminium becomes coated with oxide and the solution becomes heated. Tables are given showing the effect of varying initial concentration of the nitrates, but no general connection is apparent. Reduction is more rapid in solutions containing sulphuric acid, but the electrode is quickly attacked with the formation of a precipitate of sulphate of the electrode metal.—W. H. P.

Gas reactions; Apparatus for effecting endothermic — by means of an electric arc. J. A. Currie, Toronto, Canada. Eng. Pat. 105,953, May 1, 1916. (Appl. No. 6229 of 1916.)

A PAIR of tubular electrodes, with wide, flat, annular arcing surfaces are arranged opposite to one another, and a relatively thick annular arc is produced between the flat ends, by means of a suitable high-tension current. The air or gas is drawn or forced through the electrodes, and also drawn through the annular arc. The electrodes are cooled, the upper one by an external water-jacket, and the lower one by circulation of water in the hollow walls of the electrode.—J. B. C. K.

Generating electricity; Apparatus for —. S. A. Reed, New York. U.S. Pat. 1,225,175, May 8, 1917. Date of appl. Jan. 16, 1914.

AN extended surface of a fused acid electrolyte, containing a metallic oxide, such as a manganese oxide, which is reducible to a lower degree of oxidation, is subjected to a gas containing oxygen in an oxidising region, and to carbon or hydrogen in a reducing region. The carbon or hydrogen is supplied as fuel independently of the electrodes, and the electrolyte is maintained in a fused condition. The two regions are in open communication below the surface of the electrolyte only, and an electrode is in each case in conductive contact with the electrolyte in the oxidising and reducing regions respectively, the electrodes being included in a suitable circuit.—B. N.

XII.—FATS; OILS; WAXES.

Fat; Sources of — in Germany in 1916. W. Fahrion. Z. angew. Chem., 1917, 30, 125—126.

INCREASED cultivation of poppy, rape, and to a less extent of flax, has yielded considerable quantities of oil. Linseed oil was used as an edible oil only in certain districts of Saxony and Silesia. Last year the bulk of the oil from this source was used for munitions, and the remainder was used in the

manufacture of margarine. Sunflowers were also extensively cultivated. According to an American report from Dresden, over 300,000 kilos. of sunflower seed oil was obtained in 1915; but this estimate is decidedly too high seeing that in 1916 only 100 tons of seed was obtained from every 77 tons sown. Horse chestnuts contain in the dry condition about 6% of a yellow oil which resembles rape oil and is edible. The extraction of this oil has now been undertaken by a department of the German War Office, and the residue is used as fodder. The expectations of obtaining fat from yeast have not yet been fulfilled. Experiments made at the close of last year on the removal of the germs from cereals with a view to obtaining the oil, have given much more promising results. Wheat contains 2 to 3% of germs; rye, 2.5 to 4%; barley, 2 to 3.5%; oats, 3 to 4%; and maize, 10 to 14%. The germs contain about 12% of fat and about 35% of protein. The annual production of wheat in Germany is 15 million tons, and if only 1% of germs was separated from 10 million tons, and 10% of oil was obtained from these, the total yield of oil would be 10,000 tons. Millers are now compelled to separate the germs and to deliver them to the War Department. Rye is freed from husks in one machine and then crushed in a second machine, and the germs are separated by sifting. In the case of wheat they are sifted from the coarser and medium grains. The grain oil, when refined, is suitable for the manufacture of margarine, and for other edible purposes. In Austria the Oil and Fat Control has bought up all used coffee grounds to extract from them the 12% of oil which they contain. More than 4000 "fat-retainers" have been affixed to the sewage outlets of different towns, but so far these have not fulfilled expectation. A sample of the crude "fat" was found to contain about 50% of water and dirt. When purified by boiling with dilute sulphuric acid it yielded a yellow-grey fat which would be suitable for technical purposes.—C. A. M.

Fish oils [herring oil]; Chemical composition of —.
J. A. B. Svendsen. Tidsskrift for Kemi, 1916, Heft 14-16. Z. angew. Chem., 1917, 30, Ref., 31.

HERRING oil was found to contain the following fatty acids in approximately the proportions given:—Myristic, 6; palmitic, 17; Bull's C₁₆-acid, 12; stearic, 2; oleic, 7 to 8; isolinolic, 6 to 7; gadoleic, 10; erucic, 16; clupanodonic acid and new acids, C₂₆H₅₀O₂, C₂₂H₃₂O₃ and C₂₂H₃₄O₂, together 7; acids not identified, 10%; and residue from the distillation, 6%.—C. A. M.

Seeds of Spartium junceum; Lipolytic enzyme and oil in —. M. Raffo. Annali Chim. Appl., 1917, 7, 157—164.

THE berries of the tree *ginestra* (*Spartium junceum*, Linn.) contain a lipolytic enzyme which hydrolyses oils, very slightly in an acid medium but to a considerable extent in the presence of sodium carbonate. For example, on treating 10 grms. of sesame oil with 0.5 gm. of the powdered seed for 96 hours at 38° to 40° C. in the presence of 12 c.c. of N/10 sodium carbonate solution, the acidity due to the action of the enzyme corresponded with 19.0 c.c. of N/10 alkali. This was the highest degree of hydrolysis reached. Similar results were obtained with arachis and cottonseed oils. The most favourable alkali concentration was from 8 to 12 c.c. of N/10 sodium carbonate. The berries contain about 10% of a greenish oil, with an aromatic odour and a bitter taste. A sample had the following characters:—Sp. gr. at 15° C., 0.9103; refractometer reading (Zeiss) at 25° C., 73.5°; acid value, 9.1; saponification value, 198.6; iodine value, 134; Hehner value, 89.85; Reichert-Meissl value, 0.41. *Fatty acids*:—Sp. gr. at 17° C.

0.9208; m. pt., 26°—27° C.; and solidif. pt., 21.5° C. The oil may be classed among the semi-drying oils.—C. A. M.

Cottonseed oil; Incomplete hydrogenation of —.
H. K. Moore, G. A. Richter, and W. B. van Arsdel. J. Ind. Eng. Chem., 1917, 9, 151—162.

COTTONSEED oil was partially hydrogenated under varying conditions of temperature, pressure, etc., and the changes in its physical and chemical characters were determined. The relative proportions of oleic and linolic acids in the hydrogenated products were determined by the lead-ether method and from the iodine values of the fractions. It was found that while both linolin and olein were hydrogenated more rapidly at a high temperature (200° C.) than at a lower temperature (125° C.), the linolin was hydrogenated relatively more rapidly at the high temperature, so that under such conditions the olein tends to accumulate. In other words there is a more "selective" hydrogenation of the more highly unsaturated glycerides at the higher temperature. Increasing the pressure (e.g., to 20 and 40 lb.) has the opposite effect to increasing the temperature, the action being less "selective" than at a low pressure. The conditions necessary for obtaining a product with the same iodine value as another, but relatively higher in saturated glycerides and linolin, are the use of a lower temperature, higher pressure, more violent agitation, and a larger percentage of catalyst. The linolin may be hydrogenated to olein with only the slightest increase in the saturated glycerides, by working at a high temperature, low pressure, with little agitation, and with only a small amount of catalyst. The speed of hydrogenation of cottonseed oil increases with the increase in the temperature, pressure, agitation, and amount of catalyst. This increase in velocity of hydrogenation is approximately proportional to the increase in the pressure or amount of catalyst, whilst an increase of 10° C. between 160° and 180° C. (the ordinary temperatures in practice) increases the velocity by about 20%. The solidification point ("titer" test) of the fatty acids first falls to a minimum point before rising, which is in accordance with the fact that a mixture of two solid fatty acids melts at a lower temperature than either of its constituents. To reach a given titer at 125° C. requires about four times as long as when the hydrogenation is effected at 200° C., which corresponds with an average coefficient of about 20% for every 10° C. The chromogenetic substance which gives Halphen's reaction was destroyed after 15 mins.' hydrogenation with 2% of nickel catalyst at 150° to 160° C. The iodine value of the oil had then fallen from 104.9 to 97.6. With regard to the effect of various impurities on the activity of nickel catalysts, it was found that nickel chloride, reduced iron, and sodium chloride, sulphate, and nitrate had no effect, but that sodium sulphide gradually destroyed the activity, whilst sulphur destroyed it immediately.—C. A. M.

Hydroxy-fatty acids; Behaviour of the hydroxyl group of — on catalytic hydrogenation by means of nickel. T. Jurgens and W. Meigen. Chem. Umschau, 1916, 23, 99—102, 116—120. Z. angew. Chem., 1917, 30, Ref., 31.

ON hydrogenating the esters of ricinoleic acid, especially castor oil, with a nickel catalyst as in Normann's method, below 200° C., practically only the double bond is saturated, but above that temperature the hydroxyl group is also reduced, sometimes even more rapidly than the double bond. Ricinoleic acid itself is but little affected at the lower temperature; at the higher temperature a pronounced reduction of the hydroxyl group takes place. In the hydrogenation of castor oil

by means of nickel oxides, as in Erdmann's method, the hydroxyl group is reduced much more rapidly than the double bond. In experiments with 2% of nickel catalyst, under high pressure, the reduction of the hydroxyl group, but not that of the double bond, proceeded more slowly than under atmospheric pressure. The explanation of this is afforded by Le Chatelier's rule, according to which the increase in the tension of the steam caused by the decomposition of the hydroxyl group tends to prevent further decomposition of this group. If the steam produced in the decomposition is allowed to escape from the autoclave, the hydroxyl value of the hydrogenated fat will be considerably lower. — C. A. M.

Hardened oils: Analysis of ——. Identification of hardened marine animal oils and rape oil. W. Normann and E. Hugel, Chem. Umschau, 1916, 13, 131—133. Z. angew. Chem., 1917, 30, Ref., 108—109.

The separation of arachidic acid and identification by its melting point is insufficient in some cases to identify hardened marine animal oils or rape oil. If, however, pure stearic acid is added and the melting point again determined, a higher or a lower value will be found according to the relative proportions of arachidic and stearic acids. The authors employ the neutralisation value for a more precise determination. This is best effected by saponifying the fatty acids with excess of alkali and titrating back with hydrochloric acid. A direct determination with $N/10$ alkali is uncertain on account of the separation of these acids with high melting point during the titration.

— H. J. H.

Fats: By-products of the hydrolysis of ——. (Glycerin from waste fats.) Henkel and Co. Seifenfabr., 1916, 36, 769—770. Z. angew. Chem., 1917, 30, Ref., 108.

CRUDE glycerin, made from waste fatty materials which have undergone some decomposition by fermentation, may show abnormalities on analysis. Its specific gravity may be lower than usual and its oxidation value by the bichromate method may exceed 100%. This has been traced to the presence of *n*-propyleneglycol (trimethyleneglycol). It is stated that the quantitative determination of glycerol in presence of the latter can be made by the isopropyl iodide method of Zeisel and Stritar (this J., 1902, 992). — H. J. H.

Soap substitutes and washing powders. M. Battler, Kunststoffe, 1916, 6, 301. Chem.-Zeit., 1917, 41, Rep., 130.

Soap substitutes now on the market in Germany consist of mixtures of clay, chalk, alkali carbonates, sodium sulphate, sodium silicate, and gelatin or other binding material; a small quantity of boric acid or salicylic acid is added as a preservative. Substances containing saponin are sometimes added to the mixture. A material for washing fabrics is prepared from the tryptic enzyme of the pancreas, but this preparation cannot be used at temperatures above 10° C. A solid soap is made by heating together 10 kilos. of resin, 1.5 kilos. of sodium carbonate, and 3.5 litres of water and then adding 70 kilos. of clay, 5 kilos. of sodium carbonate, and 10 litres of water. The washing powders usually consist of mixtures of sodium or potassium carbonate, ammonium chloride, clay, and saponin, and sometimes perborates; sodium peroxide and carbon tetrachloride are also used in these mixtures. One soap powder which is sold contains 17% of soap, 3% of resin soap, and 80% of fillers, the latter including 50% of sodium carbonate and a quantity

of sodium silicate. The use of an extract of linseed has been proposed as a binding material for soap substitutes. — W. P. S.

Detergents containing saponin: Determination of active oxygen in ——. A. Grün and J. Jungmann, Seifenfabr., 1916, 36, 753—751. Z. angew. Chem., 1917, 30, Ref., 110.

The titration of active oxygen with permanganate in the presence of saponin is difficult and uncertain on account of the foam produced. The latter causes no difficulty in the iodometric determination. Extraction of the saponin with carbon tetrachloride increases rather than decreases the difficulty. Even with materials containing little saponin, extraction with carbon tetrachloride is unnecessary.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Turpentine: Oil of — recovered in the digestion of sulphate wood pulp. O. M. Halse and H. Dedichen, Ber., 1917, 50, 623—630.

IN the manufacture of wood pulp by the alkali sulphate process, generally from a mixture of spruce and pine woods, a volatile oil is obtained having a very bad odour due to mercaptans. After elimination of the sulphur compounds, either by fractional distillation or carefully regulated oxidation, the refined oil is very similar to ordinary oil of turpentine and serves as a commercial substitute. The yield of oil per ton of cellulose ranges from 1—1.5 kilos. for spruce and up to 10 kilos. for pine wood. On distillation of the crude oil with steam in presence of mercuric chloride, about 8% of a thick brown resinous fluid remains behind. The purified oil has been subjected to an elaborate process of fractional distillation and separated into two main components: α -pinene in large proportion and β -pinene in small quantity; there were probably also traces of dipentene. The β -pinene has been fully characterised and yields no pinic acid on oxidation with permanganate. This oil is therefore very similar to ordinary oil of turpentine, only differing in the fact that the β -pinene contained in the by-product oil is dextro-rotatory whereas that in the natural oil is laevo-rotatory. The α -pinene apparently is capable of passing through the alkaline digestion process without change, whereas

in the bisulphite process it is converted quantitatively into the stable hydrocarbon, *p*-cymene.

PATENTS.

(A) *Titanic oxide product and method of obtaining the same.* (B) *Composite titanic oxide pigment and method for producing the same.* (C) *Method for producing basic titanic sulphate products and pure titanic oxide therefrom.* L. E. Barton, Niagara Falls, N.Y., Assignor to The Titanium Alloy Manufacturing Co., New York. U.S. Pats. (A) 1,223,356, (B) 1,223,357, and (C) 1,223,358, Apr. 24, 1917. Dates of appl. (A), July 27, 1915, (B) and (C) Aug. 29, 1916.

(A) TITANIC oxide, containing traces of chloride, is obtained by heating a mixture of 100 parts by volume of titanium tetrachloride, 200 parts of water, and 35 parts of sulphuric acid to expel hydrochloric acid, and calcining the residue. The oxide is very friable, highly absorptive, with sp. gr. 3.5 to 3.65, white by reflected light, yellowish by transmitted light, and yields a bluish-white paint with oil. (B) A base or an "extender pigment" is suspended in a solution of titanium sulphate, the solution is electrolysed and heated, so as to precipitate basic titanium sulphate on the suspended particles, and the composite precipitate calcined. (C) A solution of titanic sulphate which may have been previously rendered basic by treatment with lime and filtering off the precipitated calcium sulphate, is electrolysed and at the same time heated not quite to boiling point, whereby a basic titanic sulphate is precipitated.

XVI.—SOILS; FERTILISERS.

Soil; Organic matter of the —. V. A study of the nitrogen distribution in different soil types. C. A. Morrow and R. A. Gortner. Soil Sci., 1917, 3, 297—331. (See this J., 1917, 226, 227, 696.)

THE distribution of the organic nitrogen of soils, as determined by the Van Slyke method of analysis, is essentially the same for all types of soil. Experiments were made to find the effect of the presence of ignited subsoil upon the relative amounts of the products formed by hydrolysing a pure protein-fibrin from blood, the ratio of ignited material to protein being 20:1. The results for ammoniacal nitrogen were not affected, but the humin nitrogen was greatly increased, and the histidine fraction disappeared completely. Hence the data found for the nitrogen distribution in soils are only useful for comparing one soil with another. The presence of carbohydrates in soils probably accounts for much of the total humin found, for they yield furfural on treatment with acid, and the furfural combines with or adsorbs other nitrogenous compounds, thus causing an apparent increase in the total humin. The true humin nitrogen, which comprises from 22.93 to 28.27% of the total nitrogen, is left in the residual soil after the hydrolysis with acid. The fraction of nitrogen removed from a colourless solution by the addition of calcium hydroxide, representing 3.26—9.21% of the total nitrogen, consists almost entirely of material of non-protein origin; it should be recorded separately. The concentration and volume of the hydrochloric acid used for the hydrolysis are without influence provided that the acid be as strong as that of constant boiling point, and the ratio of acid to soil be at least 2:1. Such acid extracted an average of 72.19% of the total nitrogen of the soils investigated, the minimum being 66.63% and the maximum 77.65%. The results of other workers gave an average of 75.19% for 37 soils of widely different origin.

—E. H. T.

Plant toxins; Soil constituents which inhibit the action of —. E. Truog and J. Sykora. Soil Sci., 1917, 3, 333—351.

THE main conclusion drawn from the investigation of the influence of calcium carbonate, finely divided quartz, and of kaolin, upon the toxic action of copper sulphate, copper nitrate, and sodium arsenite on wheat seedlings, was that the ameliorating effects of these substances is conditioned quite as much by chemical reactions as by physical actions, e.g., adsorption. The artificial cultures used were (a) 250 grms. of quartz sand, (b) 225 grms. of sand and 25 grms. of quartz flour, (c) 225 grms. of sand and 25 grms. of kaolin. These were put in tumblers, treated with a mineral nutrient solution, and then planted with wheat

seedlings. The controls of quartz sand also received the nutrient solutions, and the moisture content of all was kept at 13%. The copper sulphate was used in concentrations varying from N/300 to N/10, and in each case the toxic action was proportional to the concentration; with N/200 to N/50 solutions the plants in (b) and (c) were superior to those in (a), a result explicable on the assumption that the poison was adsorbed on the surface of the quartz and the kaolin. Similar experiments with the addition of calcium carbonate showed the remarkable ameliorating effect of this substance. The tests with copper nitrate confirmed the results obtained with the sulphate. The toxic effects of sodium arsenite, applied in concentrations of N/6400 to N/400, were marked and about equal in (a) and (c), but the plants in (b) were practically unharmed, probably owing to the oxidation of arsenite to the less poisonous arsenate by catalytic impurities present in the quartz flour. The toxicity of sodium arsenite in pure quartz sand was not influenced by the presence of calcium carbonate; the beneficial effect of quartz flour was not enhanced by the carbonates, but with kaolin the carbonate produced a marked stimulation. The toxic effect of cultures containing 200 or more parts per million of guanidine carbonate became evident after 3–5 days, and the plants wilted and died in a short time. Kaolin, on the other hand, exerted a very beneficial effect, particularly upon the root development, which was not enhanced by the presence of calcium carbonate. Seedlings grown in kaolin cultures containing 1000 parts per million of guanidine carbonate, showed roots as good as those of plants grown in sand or quartz flour containing 200 parts per million. This action may be due to the acidic nature of kaolin, which would form an insoluble compound with guanidine. Experiments with guanidine carbonate (in concentrations of 200, 500, and 1000 parts per million) on an acid red clay, both in lined and unlined cultures, showed that the ameliorating effect of the clay was greater than that of pure kaolin. Calcium carbonate had an inhibiting effect on the plants grown in the kaolin culture containing 1000 parts per million of guanidine carbonate, but was without action on the corresponding clay cultures. Experimenting with two field soils contained in large pots, it was observed that vanillin was toxic on a poor sandy soil containing neither nutrients nor limestone; but when nutrients were present, and to a lesser extent when limestone was added, the toxic action was much reduced. Similar tests on an acid silt loam soil, rich in potash and nitrogen, showed that vanillin was apparently harmless; when calcium carbonate was present, a depressing effect was noted.—E. H. T.

Soils; Extraction and saturation of—with volatile antiseptics. J. P. du Buisson. *Soil Sci.*, 1917, 3, 353–392.

The effects of treating a silt loam (Volusia) and a clay loam (Dunkirk) soil with volatile antiseptics was to increase the yields of oats and wheat subsequently grown in them. The order of efficiency was: alcohol (90%), ether, benzene, toluene, commercial gasoline; the last-named usually proved detrimental. The silt loam responded better than the clay loam. The residual effects of the antiseptic treatment upon the second crops (buckwheat following oats, and oats following wheat) were beneficial, but less marked than the effects upon the first crops. Very little difference was observed between the saturation and the extraction methods of applying the antiseptics. By extraction with alcohol, a substance was isolated which proved toxic in water cultures but harmless in the soil itself. The

antiseptic treatment enhances ammonification from the outset, the maximum being reached after 6 weeks; nitrification was inhibited during the same period, but began again after 12 weeks. The water-soluble salts in the soils showed a tendency to increase. After two croppings, the effect of the antiseptics upon ammonification and nitrification disappeared. The beneficial effects of applying volatile antiseptics are not due to a change in the physical nature of the soil, nor to the suppression of toxins, nor to the production of acid by oxidation of the antiseptic; they can only be correlated with biological changes.—E. H. T.

Soil solution obtained by the action of a hydraulic press. G. Ramann, S. März, and H. Bauer. *Int. Mit. Bodenkunde*, 1916, 6, 27. *J. Chem. Soc.*, 1917, 112, i., 311–312.

The authors point out that the analysis of drainage waters from soils does not afford an accurate means of determining the composition of the normal soil solution, as drainage only occurs when the soils are supersaturated. For this reason they adopted the method of forcing water out of the soil with a hydraulic press. Samples of 3 kilos. of soil were taken from the fields and subjected to a pressure of 300 kilos. to the square cm., the liquid expressed being then analysed for calcium, magnesium, sulphates, phosphoric acid, and potassium. The sampling was done on six different occasions over a period lasting from May to October; both surface and subsoil were used. The calcium content was found to vary considerably in the surface soil, but in the subsoil it seemed fairly constant, except for a rise in mid-summer. Potassium, contrary to the generally accepted view, behaved very much like calcium, that is, its content fluctuated according to the general concentration of the soil solution, rising when evaporation took place and being lowered by spells of wet weather. Further, there was evidence of potassium and calcium being transported from the subsoil to the surface during a prolonged period of drought, but no evidence was obtained that adsorption exerted any regulating effect on the concentration of the soil solution. The exchange of bases only occurred when the proportion which the dissolved substances bore to one another was altered. The authors suggest that the selective action of the plant roots, by throwing the soil solution out of equilibrium, would have a considerable effect in bringing fresh supplies of nutrient substances into solution. They state also that the pressure method of obtaining soil water is only applicable in the case of soils made up of very fine particles or containing a considerable amount of humus.

Garbage tankage: its composition, the availability of its nitrogen, and its use as a fertiliser. P. J. Schroeder. *J. Ind. Eng. Chem.*, 1917, 9, 513–518.

In about half of the large cities of the United States the garbage, i.e., household refuse, food waste, etc., is treated for recovery of grease, and the residual matter, known as tankage, is of value as a low-grade fertiliser. In 1914 about 1,200,000 tons of garbage was thus treated, and yielded, besides grease, 173,000 tons of tankage valued at about £230,000. The garbage is first sorted, to remove broken glass, tins, etc., and then treated by one of the following methods:—(1) heating with steam under pressure, pressing out the water and liberated fats as completely as possible, separating the fats from the water by settling and skimming, and in some cases extracting the dried residue with gasoline to recover more fat; (2) crushing to uniform size, drying, extracting with gasoline, and grinding the residue; (3) boiling with gasoline to evaporate moisture and extract fats at the same time. In some plants the aqueous extract obtained by the first method is

concentrated to a syrupy liquid, known as "stick," and mixed with the tankage before the latter is dried. Garbage tankage is a coarse brown powder, either granular or finely fibrous, and usually contains pieces of broken bone, glass, or crockery, the amount of which depends on the efficiency of the sorting of the garbage. The accompanying table shows the average percentage composition of garbage (75 samples) and tankage (20 samples from different plants, 4 of which did not remove fats).

	Moisture.	Ash.	Ether extract.	Potash.	Nitrogen.	P ₂ O ₅ .	Combustible matter.
Garbage	73.78	3.60	5.32	0.27	0.7	0.43	22.65

* Percentage referred to dry matter.

Efforts have been made recently to utilise tankage as a cattle food, and flotation processes have been devised to remove particles of hard matters. It is used most extensively, however, as a base in the preparation of mixed fertilisers, for which purpose its physical characters render it well suited. A certain quantity has been used with success as a complete, low-grade fertiliser. Its high content of organic matter increases its value for soils deficient in humus. It commands a relatively low price owing to a widespread belief that its nitrogen is of very low manurial value, but from experiments described the author concludes that this belief is unwarranted. The alkaline permanganate method indicated that 40% or more of its nitrogen is "available" (as compared with 57% in the case of cottonseed meal), and good results were obtained also in experiments on nitrification by Lipman's method (this J., 1916, 1168). Nearly one-quarter of the total nitrogen in tankage is soluble in water, and this proportion could be increased considerably by treatment with sulphuric acid.—J. H. L.

Potash [in fertilisers]: Study of the determination of — chiefly concerned with the Lindo-Gladding method. P. L. Hibbard. J. Ind. Eng. Chem., 1917, 9, 501—513.

THE author has made an exhaustive study of the method of the U.S. Association of Official Agricultural Chemists for the determination of potash in fertilisers (U.S. Dept. Agric., Bureau of Chem., Bull. 107). The method consists in extracting the material (10 grms.) with boiling water, precipitating iron, calcium, phosphates, etc., with ammonia and ammonium oxalate, evaporating an aliquot part of the filtrate (corresponding to 1 gm. of material) with sulphuric acid, and incinerating, and determining the potash in the residue as platinichloride. The following are some of the author's conclusions. Ammonium oxalate should not be added until the liquid is alkaline with ammonia (which should not be used in excess), and if there is more than enough phosphoric acid to combine with the alkaline-earth bases, no oxalate should be added, as it increases the amount of phosphate remaining in solution. When much phosphate is present a special procedure is necessary—either addition of excess of calcium and re-precipitation, or greater dilution, for potash is adsorbed by the gelatinous phosphate precipitate. Addition of a little sugar during evaporation reduces spattering. Carbon should be burnt off at a low temperature and the residue raised to a moderate red heat only for a few minutes. For accurate results in the precipitation of potash, the concentration of the latter should not be sufficient to produce an immediate precipitate with platinum chloride, and the amount of the latter added should not be much more than required for the

potash, as sodium platinichloride is not readily washed out of the precipitate by alcohol. Free sulphuric or nitric acid or organic matter should not be present, but evaporation should be stopped while some free hydrochloric acid still remains. Where much soda is present the potash is best first precipitated as cobaltinitrite. For the collection of the platinichloride an ordinary Gooch crucible with asbestos felt gives more accurate results, though it is less convenient, than a filter

tube. Drying may be carried out between 100° and 140° C., but 1 hour at 120° C. is usually sufficient. The perchlorate method of determining potash was found to be longer, more difficult, and more costly than the platinichloride method. A bibliography of the subject is appended to the paper.—J. H. L.

Extraction of potash from silicate rocks. Ross. See VII.

XVII.—SUGARS ; STARCHES ; GUMS.

Beet molasses: its composition and utilisation. S. J. Osborn. Met. and Chem. Eng., 1917, 16, 436—443.

THE paper opens with some observations on the conventional melassigenic factor of 5 for the ash of molasses which is based on the fact that in both beet and cane molasses the quantity of sugars present is five times that of the ash. In beet molasses sucrose with but a trace of invert sugar is present, whilst cane molasses contain sucrose and invert sugar in approximately equal proportions. The various precipitation processes for the recovery of crystallisable sugar from molasses are described and discussed. The baryta process appears to be only in operation at one place, Wallaceburg, Ont., Canada. It is carried out in iron tanks with false bottoms of 60-mesh wire. The required amount of barium hydroxide is first introduced in the form of a milk, followed by the undiluted molasses; the precipitate forms readily on stirring at 40°—50° C. The pasty mass is drained on the screen, washed first with the sweet water from a previous charge, then with water containing a little barium hydroxide. The washed precipitate is suspended in water, treated with carbon dioxide, and the filtered solution mixed with fresh juice. The main difficulty is the regeneration of the barium oxide, which requires an extremely high temperature in an electric furnace. In Germany the strontia process is employed, being worked at five large factories obtaining molasses from a number of beet factories; the strontia process is combined with the destructive distillation of the mother-liquors. In the United States, Steffen's lime process is worked. Powdered quicklime is added slowly, with mechanical stirring and artificial cooling. The apparatus has a large central well and several hundred cooling tubes, and a propeller draws the liquid down through the well, forcing it up through the tubes. When the precipitate of tricalcium succinate has formed, it is drained in filter-presses, washed with cold water, and used for liming fresh juice. One of the main essentials for satisfactory working is the use of

extremely finely ground lime, graded from the ball mill by means of an air-current so that 98–99% will pass through a 200-mesh sieve. The presence of more than 2% of water in the form of hydroxide is objectionable. Calcium oxide will combine with sugar in preference to water so long as the former is in excess, but if owing to slow stirring, too fast or uneven addition, or too coarse powder, the lime is locally in excess, it becomes hydrated and useless; excessive foaming may cause the same defect. The theoretical quantity of lime required is 49% of the sugar, but 100% is considered good in practice. The temperature must be as low as possible, but good results can be obtained up to 17° C. The economy of lime is greater the higher the concentration of the sugar solution, but the liquid becomes too thick for efficient circulation; in Colorado the molasses is diluted 7–10 times to give a solution containing 5–7% of sucrose. The addition of lime is continued so as to leave about 0.4% of sucrose in the mother liquor; beyond this point the consumption of lime is excessive. Thorough washing of the filter-press cake is difficult because the cake is somewhat soluble, and constant attention is required to avoid "channeling." The great disadvantage of the Steffen process is that certain impurities are co-precipitated with the sucrate and accumulate in continuous work, making it necessary to discard a portion of the molasses at regular intervals, as these impurities render the mass extremely viscous and interfere with crystallisation. A comparison of the "purity" of the juice obtained by decomposition of the three kinds of sucrate shows: barium process 93.65, strontium 88.33, and calcium 81.22%. —J. F. B.

Sorghum juice; Chemical changes caused by defecation of — for syrup manufacture. A. K. Anderson. J. Ind. Eng. Chem., 1917, 9, 492–499. (See also Bryan, this J., 1912, 696.)

In Minnesota, in the larger factories, sorghum juices destined for the production of syrup are defecated by lime; in the smaller ones as a rule no lime is added but impurities are skimmed off from the juice in the course of evaporation. A third method which has been proposed, but not yet adopted, is to heat the juice for 30 mins. with acid calcium phosphate (e.g., 5 lb. per 1000 gallons) and then neutralise with lime. The acid phosphate inverts some of the sucrose present and thus tends to prevent crystallisation of the resulting syrup. Moreover, the precipitate of tricalcium phosphate formed has a clarifying action on the juice. The author has studied the effect of all these methods of defecation. The results are discussed in detail. To judge by the commercial quality of the products the phosphate method gives rather better syrups than the lime method, but, taking into account the cost of working, the lime method is considered preferable. As regards the amount of lime to be used, that calculated from a titration of the juice with sodium hydroxide in presence of phenolphthalein produces proper defecation with the minimum darkening of the juice.—J. H. L.

p-Tolyhydrazones of L-arabinose, rhamnose, fucose, D-mannose, and D-galactose. A. W. Van der Haar. Rec. Trav. Chim. Pays-Bas, 1917, 36, 316–351.

The *p*-tolylhydrazones of L-arabinose, rhamnose, fucose, D-mannose, and D-galactose (m. pts. 160°, 166°, 169°, 190°–191°, and 168° C. respectively) were prepared by heating equal quantities of sugar and purified *p*-tolylhydrazine in 20 parts of 96% alcohol until all the sugar had dissolved and for 15 mins. longer. The cooled liquids in all cases deposited crystals of hydrazone within 24 hours, and the products were re-crystallised from alcohol or water. The characters of these hydrazones are described,

with illustrations. They are all less soluble than the corresponding phenylhydrazones, and might serve for identifying any one of the sugars named, in presence of xylose, levulose, or dextrose, none of which gives a crystalline product within 24 hours under the conditions stated. Mannose, which yields a very insoluble tolylhydrazone of high melting point, can also be similarly detected in presence of other monoses, and arabinose in presence of rhamnose within certain limits.—J. H. L.

Starch; Polarimetric determination of — in the presence of other optically active substances. C. Baumann and J. Grossfeld. Z. Unters. Nahr. Genussm., 1917, 33, 97–103. J. Chem. Soc., 1917, 112, ii, 223–224.

THE method described is particularly useful for the estimation of starch in products which contain starch paste, dextrins, and sugars, and depends on the fact that starch, whether raw or heated, is precipitated completely by lead tannate when the latter is formed in the starch solution. Ten grams of the substance under examination is shaken for 15 mins. (or for 1 hour if dextrins are present) in a 100 c.c. flask with 75 c.c. of water; 5 c.c. of 10% tannin solution is then added, followed by 5 c.c. of basic lead acetate solution, and the mixture is diluted with sodium sulphate solution to 100 c.c. After filtration, 50 c.c. of the clear filtrate is mixed with 3 c.c. of 25% hydrochloric acid and heated for 15 mins. in a boiling water-bath, then cooled; 20 c.c. of 25% hydrochloric acid and 5 c.c. of sodium phosphotungstate solution (12 grms. of sodium phosphate and 20 grms. of sodium tungstate per 100 c.c.) are added, the mixture is diluted to 100 c.c., filtered, and polarised in a 200 mm. tube. Another portion of 5 grms. of the sample is heated directly with hydrochloric acid (compare Ewers' method, this J., 1908, 238) and the solution polarised after the addition of a further 20 c.c. of hydrochloric acid and clarification with sodium phosphotungstate. The difference between the two polarimeter readings is multiplied by 5.441 to obtain the percentage of starch present; this factor is calculated from the average rotatory power of various starches, the average being $[\alpha]_D = +183.7^\circ$. On account of the presence of acetates in the first part of the process, it is necessary to add 3 c.c. of hydrochloric acid, instead of 2 c.c. as given by Ewers, to bring the acidity of the mixture to the required concentration; the additional quantity of hydrochloric acid introduced after the inversion is for the purpose of insuring the complete precipitation of organic bases, alkaloids, etc., which may be present; sodium phosphotungstate fails to effect their entire removal from the more dilute hydrochloric acid solution. The error of the method does not exceed 0.2% when dealing with substances containing from 10 to 60% of starch together with large proportions of sucrose, dextrose, dextrins, milk, etc.

XVIII.—FERMENTATION INDUSTRIES.

Enzyme actions; Domestic application of — in Eastern countries. H. C. Prinsen Geerligs. Nederland. Chem. Ver., Dec. 28, 1916. Z. angew. Chem., 1917, 30, 256–257.

A MILK-LIKE product produced by grinding soya beans with water contains 6.9% of total solids, 3.13% of proteins, and 1.89% of fat; this product, unless boiled, rapidly undergoes lactic acid fermentation, and a cheese may be obtained by the

addition of a quantity of the fermented liquid to a larger volume of the normal liquid. To prepare an extract resembling meat extract, the cooked beans are subjected to the action of fungi which are found on the leaves of a species of mallow (*Hibiscus tiliaceus*), the mass is then extracted with salt solution, spices are added to the extract, and this is then concentrated to a thick syrup. A similar product is prepared from a mixture of soya beans and rice by the action of fungi. Another food is obtained by submitting soya bean cakes to the action of fungi found on banana leaves, etc. The fungi found in rice meal and rice straw are utilised for converting rice meal into alcohol: rice meal may be saccharified by treatment with the fungi occurring on banana leaves and the liquid obtained is subsequently converted into rice wine. One of the most important results of enzyme action is the production of sugar in the palm: the stem of the latter is free from sugar but contains large quantities of starch: the conversion of the starch into sucrose proceeds in the tree, but laboratory experiments with the separated enzyme resulted in the formation of dextrose alone.

—W. P. S.

Enzymes; Formation of —. M. Jacoby. Biochem. Zeits., 1917, 79, 35—50. J. Chem. Soc., 1917, 112, i., 305. (See this J., 1916, 901, 1269.)

THE following substances were found to stimulate the formation of a urease by bacteria: dextrose, *d*-galactose, glycerol, *dl*-glyceraldehyde, dihydroxyacetone, pyruvic acid, and lactic acid. The stimulating action of these substances was great. A stimulating action was shown, but less markedly, by *d*-lævulose, *d*- and *l*-arabinose. Mannose, *d*-sorbose, rhamnose, heptose, the polysaccharides, glucosides, and the sugar alcohols were without action.

Enzyme action. I. Enzymic degradation of polypeptides. E. Abderhalden and A. Fodor. Fermentforschung, 1916, 1, 533—596. J. Chem. Soc., 1917, 112, i., 306—309.

THE authors have investigated the action of enzymes on synthetic polypeptides which are formed from such amino-acids as occur naturally. All comparative experiments were performed with one and the same solution of the enzyme prepared in a definite manner. Uniform conditions were also maintained in other respects, and it is emphasised that the results obtained are only valid under these conditions and do not apply, for example, to processes within the cell. Solutions of the enzyme were prepared from dried yeast according to Lebedev; it was found that different consignments of the preparation from the same firm showed considerable differences in activity. Strictly comparable experiments were therefore always carried out with the expressed juice of yeast from a single consignment. The juice was fairly acid to litmus, and was therefore nearly neutralised, since otherwise the desired regulation of the solutions could not be obtained. The yeast-juice was preserved until constant in its behaviour towards glycyl-*l*-leucine as substrate. The greatest stability of peptase occurs with a hydrogen-ion concentration of about 3×10^{-7} : variation in either direction caused a distinct decomposition after one hour at 25° C. and the sensitiveness was greater towards an increase in the hydrogen-ion than towards an increase in the hydroxyl-ion concentration.

The rate of fission of a number of dipeptides by yeast was studied. The course of the degradation at different H^+ and OH^- concentrations (usually within the limits $p_H=6.5-8.5$) was followed: it was found that not merely the rate of reaction but also its nature is dependent on them. Increase in the concentration of the yeast extract greatly

diminishes the rate of reaction, but this depends also on the acidity or alkalinity and on the amount of yeast peptase present. It is true for glycyl-*l*-leucine in very dilute acid or faintly alkaline solution ($p_H=6.20-7.50$) in the presence of an excess of yeast extract, whilst increase of an originally very small amount in this interval increases the amount hydrolysed. Beyond $p_H=8$, a quantity of yeast extract which previously diminished the reaction velocity, is found to cause a further increase. The amino-acids which are formed as products of hydrolysis can exert a powerful retarding action: glycine behaves thus in alkaline, *l*-alanine and *l*-leucine only in acid solution. The optimum hydrogen-ion concentration has been determined for a number of polypeptides with the following results, the values of p_H being enclosed within brackets: glycyl-*l*-leucine (8.41, 8.50); *l*-leucylglycine (7.50, 7.56); *d*-alanyl-*l*-leucine (7.30—8.13); glycyl-*d*-alanine (7.30—7.91); *d*-alanyl-*l*-leucine (6.76, 6.85); *l*-leucyl-*d*-alanine (6.80—7.89); *dl*-leucyl-*l*-aspartic acid, 2% (6.76); *dl*-leucyl-*l*-aspartic acid, 10% (6.80); *l*-leucylglycylglycine (7.26); *l*-leucyldiglycylglycine (7.29); *l*-leucyltriglycylglycine (7.28); *l*-leucylpentaglycylglycine (6.24). The results which have been obtained support the view that enzymes act as colloidal catalysts and are closely connected with the work of Bredig and his co-workers on "inorganic ferments." The assumption that an enzyme is active towards a definite grouping of atoms is not supported by the authors' experiments.

Pyruvic acid; Production of — by biochemical oxidation of lactic acid. P. Mazé and M. Ruot. Comptes rend. Soc. Biol., 1916, 79, 706—710. J. Chem. Soc., 1917, 112, i., 310. (Compare Mazé, this J., 1913, 503; Fernbach and Schoen, this J., 1914, 97, 707.)

Amphomyces Roucii (a mould related to *Mucor*) and another undetermined fungus, parasitic on maize, oxidise lactic acid to pyruvic acid in a solution containing no other carbon compound, and ultimately also destroy the pyruvic acid formed. The yield is better with free lactic acid than with calcium lactate, for in the latter case the solution becomes alkaline and growth is inhibited. As may be foreseen, the respiratory quotient is low (0.77—0.90). Similar effects may be obtained with sucrose in thin layers of a solution not more concentrated than 1% (in order to avoid the formation of alcohol).

Pentoses and compounds of pentoses; Utilisation of certain — by *Glomerella cingulata*. L. A. Hawkins. Amer. J. Botany, 1915, 2, 375—388.

PREVIOUS investigators have shown that pentoses and pentosans are of some value as food for higher animals, but the latter appear to secrete no enzyme capable of hydrolysing pentosans, this transformation being probably effected by intestinal bacteria. Some of the invertebrates utilise pentoses readily and can probably hydrolyse some pentosans. Pentoses have been found to be a good source of carbon for certain fungi, and there is evidence of decomposition of pentosans by enzymes secreted by fungi, though the products of such decomposition have apparently not been identified. In experiments with *Glomerella cingulata* the author found that this fungus can utilise dextrose, xylose, arabinose, xylan, or arabin as sole source of carbon. The three sugars are most efficiently utilised, xylose perhaps best of all. The pentosans are much less readily assimilated, and arabin less readily than xylan. The presence of a pentosanase in filtered aqueous extracts of the fungus mycelium, was also demonstrated by the conversion of xylan into xylose, the latter being isolated in crystalline form.—J. H. L.

Glycerol; β -Monoglucoside of — obtained by biochemical synthesis. E. Bourquelot, M. Briet, and A. Aubry. *Comptes rend.*, 1917, 164, 831—833.

A PRODUCT of the action of emulsin (β -glucosidase) on dextrose and glycerol, obtained in a non-crystalline form two years ago, has since crystallised on prolonged contact with alcohol and ether at low temperatures. It is a monoglucoside of glycerol, very soluble in alcohol; m. pt. 130°—135° C., and $[\alpha] = -28.16^\circ$. It is non-reducing, and is hydrolysed by acids and by emulsin.—J. H. L.

XIXa.—FOODS.

Proteins: Chemistry of the —. E. Herzfeld and R. Klinger. *Biochem. Zeits.*, 1917, 78, 349—353. *J. Chem. Soc.*, 1917, 112, i, 300—301.

WHEN serum is dried in a film on a glass plate, a product is obtained which is soluble in water. If, however, the product is ground up in a mortar, a powder is formed which is no longer completely soluble. The following explanation is offered of this "mechanical denaturation" of the protein. The scale preparation is considered to consist of spheres of the protein surrounded by a layer of protein degradation products, to the presence of which the disaggregation of the protein in water is due (this *J.*, 1914, 707; 1915, 811). By grinding in a mortar, the spheres are broken up, and fresh surfaces are exposed on which there are no degradation products, and owing to the exposure of surfaces of protein without these products, complete solubility is no longer possible.

Amino-acids [from proteins]: Improvements in the copper method for determining —. P. A. Kober. *J. Ind. Eng. Chem.*, 1917, 9, 501—504.

THE author has previously described (see Kober and Sugiora, *J. Amer. Chem. Soc.*, 1913, 35, 1516) a method for determining amino-acid nitrogen, in which a solution of the amino-acids containing sodium borate as "buffer salt" is treated with a suspension of cupric hydroxide. The latter combines with the amino-acids (and polypeptides) forming complexes, some of which are soluble and are determined after filtration by titrating the filtrate with thiosulphate in presence of potassium iodide, whilst others are insoluble and require to be freed from excess of cupric hydroxide by treatment with potassium bicarbonate before their amount can be determined. A further modification is designed to make allowance for the presence of polypeptides the free amino groups of which react with the copper hydroxide. In the present paper some modifications of a practical nature are suggested which are of general interest. In using weighed quantities of copper sulphate crystals for standardising the thiosulphate solutions, the somewhat variable moisture content of the crystals introduces a possible error. The author suggests drying the crystals to the stage of monohydrate in a tared tube through which a current of air dried by calcium chloride is passed, the tube meanwhile being immersed in paraffin at 250° C. Suspensions of

cupric hydroxide which retain for months their blue colour and their original reactivity towards amino-acids, may be prepared by precipitating copper sulphate solutions with slightly less than the calculated quantity of alkali, with the precautions previously indicated (*loc. cit.*). A saturated solution of potassium iodide containing soluble starch and acetic acid can be kept colourless for months when covered with a layer of mineral oil in a flask fitted tightly with a siphon tube, the outer and lower end of which is provided with an automatic pipette for drawing off small quantities of solution as required, and with an air inlet tube fitted with a trap containing strong alkali to wash the entering air. At the outset the solution in the flask is treated with a few c.c. of copper sulphate solution and after half an hour carefully rendered colourless by means of thiosulphate solution and then boiled for half an hour.—J. H. L.

Arginine in proteins: Determination of —. B. C. P. Jansen. *Chem. Weekblad.*, 1917, 14, 125—129. *Z. angew. Chem.*, 1917, 30, Ref., 114.

THE arginase for use in the method described (this *J.*, 1917, 562) is prepared from the liver of a recently killed dog or cat. This is rinsed with water, and triturated to a thin paste with quartz sand, water, and toluene. The paste is submitted to dialysis, centrifuged for a short time, and the resulting turbid liquid treated with 2 vols. of alcohol and 1 vol. of ether. The precipitate is centrifuged, washed with alcohol, and suspended in water. The arginase preparation thus obtained will keep unaltered for 3 months in an ice-chest. Arginase can be used for the determination of creatine as well as of arginine.

Lime: Detection of — when used as a neutraliser in dairy products. H. J. Wichmann. U.S. Dept. of Agric., Bull. No. 521, May 7, 1917, 1—22.

THE ash of milk, of unneutralised cream, and of unsalted butter made from the same contains from 21 to 23% of calcium oxide; when lime has been added to the cream in the process of manufacture, the quantity of calcium oxide in the ash increases to above 25%, the increase varying with the amount of lime added and the degree of washing. The same holds good with salted butters, provided that the calcium oxide is calculated on the salt-free ash. Some dairy salts contain calcium sulphate and this increases the calcium content of the ash, but a determination of the sulphate in the ash would allow a correction to be made for this impurity. The ash of milk, cream, or butter is determined in the usual way, and, in the case of salted butter, the quantity of salt in the ash is determined gravimetrically. To determine the calcium oxide in the ash, the latter (obtained from 10 to 50 grms. of the sample) is dissolved in dilute hydrochloric acid, the solution neutralised with sodium hydroxide, acetic acid is added, and the calcium precipitated from the hot solution by addition of ammonium oxalate.

—W. P. S.

Pepsin: Experiments with — to replace rennet [in cheese making]. D. W. Stuart. *J. Bd. Agric.*, 1917, 24, 57—59.

IT was found that 1 oz. of pepsin powder (1—3000) was equivalent, in cheese making, to 12 oz. of standard rennet extract, and that it was impossible to detect any difference between cheese made with pepsin and that made with rennet. To prepare the pepsin solution for use, 2 lb. of common salt and 3 oz. of boric acid should be dissolved in 1 gall. of water, the solution boiled, cooled to 104° F. (40° C.), and 13½ oz. of the pepsin powder then added.—W. P. S.

BLOOD from which the fibrin has been separated to retard coagulation is converted into an easily digestible, water-soluble mass by freezing it, allowing it to thaw, and evaporating it to dryness *in vacuo*, at about 30° C., on surfaces heated above the coagulation temperature of the albuminous constituents. The dried material should not be heated above 40° C.—F. Sp.

XIXB.—WATER PURIFICATION; SANITATION.

Water analysis; Contributions to —. L. W. Winkler. Z. angew. Chem., 1917, 30, 113—116.

Standard caustic soda solutions. To prevent standard solutions of caustic soda from undergoing change, the solution should be made up with one-third of its volume of glycerol. *Hardness.* The modern method of ascertaining the hardness of a water is to determine the alkalinity and to subtract the "carbonate" hardness calculated from this, from the total hardness. For these results, the terms "carbonate" hardness and "remaining" hardness should be used, and the terms temporary and permanent hardness reserved for the results of the soap test. The reason for this is that the two methods give different results for the same water. *Determination of bromine.* The residue from a litre of the water is distilled after oxidation with permanganate in presence of manganous sulphate, and the bromine in the distillate titrated with arsenious acid. *Determination of iodine.* The residue from a litre of the water evaporated with caustic soda is ignited and dissolved, the solution acidulated and shaken with carbon tetrachloride. The depth of the colour produced is proportional to the amount of iodine present. *Determination of arsenic.* 100 c.c. of the water, or 1 litre concentrated to 100 c.c., is introduced into a flask with

zinc and sulphuric acid, the neck plugged with cotton-wool soaked in lead solution, and the mouth of the flask tied over with white linen moistened with gold chloride solution. The reddish-blue colour produced is proportional to the amount of arsenic present. *Mineral analysis.* The results of a complete mineral analysis should be checked by dividing the weights of each anion and cation found by its equivalent; the resulting quotients for the anions are added together, also those for the cations; the two sums should equal one another.—J. H. J.

Antiseptic power and valency; Relationship between —. E. Friedberger and G. Joachimaghu. Biochem. Zeits., 1917, 79, 135—151. J. Chem. Soc., 1917, 112, i., 306.

IN experiments with bacteria and protozoa it was found that compounds of trivalent arsenic (sodium arsenite and salvarsan) have a greater toxic effect than the compounds of quinquivalent arsenic (sodium arsenate and atoxyl). A similar difference was observed between the compounds of trivalent and quinquivalent antimony (tartar emetic and potassium pyroantimonate respectively). Arsenites inhibit the action of yeast to a greater extent than do arsenates.

Garbage tankage; its composition, availability of its nitrogen, and its use as fertiliser. Schroeder. See XVI.

PATENTS.

Water; Method for obtaining pure — from salt water. F. T. Evans, Assignor to G. H. Benjamin. New York. U.S. Pat. 1,225,118, May 8, 1917. Date of appl., July 1, 1913.

SALT water in a state of agitation is heated by a steam coil, and the vapour given off, containing a little salt, is passed into a vessel in which it is superheated by another steam coil at a higher temperature and thus expanded. In the second heating, the salt is deposited. The superheated vapour is subsequently condensed.—J. H. J.

Water for drinking and industrial purposes; Removal of iron and manganese from —. Permutit-Filter Co., G. m. b. H., Berlin. Ger. Pat. 297,300, Feb. 14, 1911. Addition to Ger. Pat. 211,118.

NATURAL waters which contain iron or manganese in organic combination are usually yellow or brown in colour, have an inky taste, and may remain clear for several days. The iron or manganese may be removed by treating the water with a quantity of permanganate insufficient to precipitate the total iron or manganese content, and passing it over higher oxides of manganese deposited on natural or artificial zeolites.—F. Sp.

Septic tank. W. C. Ferguson. St. Louis, Mo. U.S. Pat. 1,221,913, May 8, 1917. Date of appl., Nov. 16, 1916.

A VERTICAL cylindrical chamber is provided near the middle of its length with a conical throat piece, the walls of which slope downward and inward. Lugs project inward from the throat piece and support an upright conical partition, thus forming a settling chamber above and a digesting chamber below. Solid particles in the sewage introduced into the settling chamber escape into the digesting chamber through the constricted passage between the throat piece and the conical partition.—W. F. F.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Opium; Identification of—with the aid of meconin and meconic acid. O. Tunnmann. *Apoth.-Zeit.*, 1916, 31, 499–500, 503–501. *J. Chem. Soc.*, 1917, 112, ii., 226.

Zinc chloro-iodide is a suitable reagent for the microchemical detection of opium in broken pieces and dust; when the preparation is gently warmed with the reagent, the polygonal epidermal cells of the poppy capsule are well defined, the secondary membranes being coloured violet-blue, the primary deep yellow. The meconic acid content of opium may fall as low as 1.5%. In using Autenrieth's method of testing for meconic acid, it is necessary to filter the solution of magnesium meconate at the boiling point. In addition, it is frequently advisable to decolorise the aqueous solution of the residue obtained from the alcoholic extracts by means of benzene previous to boiling with magnesium carbonate. The maximum meconin content in opium in seven cases investigated was 0.112%. Little reliance can be placed on the sulphuric acid test for meconin. The copper, silver, ferrous, and pyridine salts of meconic acid are suitable for its microchemical detection. The copper salt forms 3–5–10 μ long, pale yellow, intermingled needles and rods with occasional nodules. Limit of sensitiveness, 40–50 μ g. In spite of their smallness, the crystals shine brightly between crossed nicols. The silver salt appears under the microscope as yellow, occasionally almost black, needles (diameter, 15–25 μ) grouped in clusters, less frequently as colourless crystals, of length up to 20 μ . In polarised light, the smaller nodules show a dark cross, the larger groups appear grey and greyish-brown. Extinction in the single crystals is parallel to the long axis. The limit of sensitiveness is 5 μ g. The ferrous salt is prepared by adding a grain of dehydrated ferrous sulphate to a drop of meconic acid; the mixture is warmed until a pale red solution is formed. After five to ten minutes, the formation of reddish-brown nodules and single crystals is observed, the latter gradually forming aggregates. All the crystals glow red in polarised light and show strong pleochroism. Limit of sensitiveness, 15–20 μ g. The pyridine salt forms long, fine, colourless, single, prismatic needles, occasionally grouped in sheaves; the mean length of the needles is 60–120 μ and mean breadth 2.3 μ . Between crossed nicols they appear pale grey. Limit of sensitiveness, 50 μ g. Lastly, the reactions with zinc chloro-iodide, potassium bismuth iodide, and potassium iodide-iodine can be used. The former yields a yellow, amorphous precipitate, whilst the other reagents give yellow or yellowish-brown nodules and sun-like crystal aggregates which, with the last-named reagent, attain a diameter of 300–400 μ .

Ipecacuanha; Alkaloids of—II. P. Karrer. *Ber.*, 1917, 50, 582–586. (See also this J., 1916, 1177).

In the previous paper the production of the iodide of a quaternary base, dehydroemetine, was recorded as the result of the oxidation of emetine with iodine. This is identical with the rubremetine of Carr and Pyman (this J., 1911, 761); its salts are not decomposed by sodium hydroxide. The revised formula for the iodide is $C_{25}H_{43}N_2O_4I$; the base thus contains 7 hydrogen atoms less than emetine and it is suggested that in the oxidation two tetrahydroisoquinoline rings are oxidised, one with a secondary N-atom and the other with a tertiary N-atom forming part of two contiguous rings. Dehydroemetine may be reduced both in alkaline and acid media, giving different products

in the two cases. On reduction with zinc dust and sulphuric acid it yields a white substance, $C_{25}H_{40}N_2O_4$, which is not identical with emetine and has therefore been named isometine. Neither isometine nor its salts, nor the product of its complete methylation, $C_{29}H_{52}N_2O_4 \cdot CH_3 \cdot (CH_3)_2$, with methyl iodide and sodium carbonate, show any tendency to crystallisation. Emetine and isometine behave differently in their colour reactions with diazotised sulphanilic acid:—Emetine couples with this reagent only in alkaline solution in presence of sodium carbonate; if the liquid be acid it remains yellow. Isometine coagulates in neutral solution; on the addition of sodium carbonate the liquid clears but if this solution be then acidified the colour changes to a deep violet-blue. Isometine is rather less toxic than emetine.—J. F. B.

Aconite alkaloids. Pyraconiline and pyraconine H. Schulze and A. Liebm. *Arch. Pharm.*, 1916, 254, 567–583. *Z. angew. Chem.*, 1917, 30, Ref., 124.

ACONITINE and japaconitine yield the same pyraconitine, and also, contrary to the statement of Dunstan and Read (this J., 1899, 1153), the same pyraconine. Of the nine oxygen atoms of pyraconitine, $C_{39}H_{43}(11)NO_9$, four are present in methoxyl and two in hydroxyl groups and two in a benzoyl group; the remaining one is probably in the form of an ether (alkylene oxide) linkage. Pyraconitine is an N-methylated tertiary base. It yields pyraconine, $C_{25}H_{38}(37)NO_8$, and benzoic acid when heated with alkali or water. Pyraconine is not identical with pseudaconine. Its hydrochloride crystallises with 24 mols. H_2O , melts at 135°C., and has $[\alpha]_D^{20} = -121.6$ (see also Dunstan and Carr, this J., 1894, 172).

Sparteine; Anomalous solubility of—A. Valeur. *Comptes rend.*, 1917, 164, 818–820.

A MIXTURE in equal volumes of sparteine sulphate and sodium carbonate solutions remains clear at ordinary temperatures but forms a milky precipitate on raising the temperature to 30°C., and the solution clears again on lowering the temperature. The precipitate may be due to the formation either of a basic sulphate of sparteine or the free base. A saturated aqueous solution of sparteine gives a precipitate on slight elevation of temperature, and at other concentrations, down to 0.14 gm. per 100 c.c., the more dilute the solution, the higher is the temperature necessary for precipitation. The base is less soluble in sodium carbonate than in water, so that even at a concentration of 0.01% in 12.3% sodium carbonate solution, turbidity occurs by immersion in boiling water. Similar anomalies are shown by several piperidine bases.—J. N. P.

Tobacco leaves; Critical examination of the methods of estimating nitrogenous substances in—G. Paris. *Staz. sperim. agrar. ital.*, 1916, 49, 405–421. *J. Chem. Soc.*, 1917, 112, ii., 227.

AMMONIA-NITROGEN is not completely precipitated by phosphotungstic acid in sulphuric acid solution, but is partly contained in the amino-nitrogen estimated by difference. The general methods of estimating amino- and protein-nitrogen also yield inexact results. The volumetric estimation of nicotine is accurate if certain precautions are taken. The following methods are proposed: Water, total nitrogen, and nicotine are estimated in the tobacco itself, total nitrogen, protein nitrogen, nicotine nitrogen, ammonia nitrogen, nitric acid nitrogen, and amino-nitrogen in the aqueous extract. The latter is obtained by agitation for six hours with water at 30–35°C. Total nitrogen is estimated by the Kjeldahl method, nicotine by Bertrand and Javillier's method (by

precipitation as silicotungstate and weighing the silica and tungsten oxide after ignition, etc.), soluble protein-nitrogen according to Stützer, ammonia-nitrogen by distillation under diminished pressure, nitric acid nitrogen by the Schlesing-Wagner method. For the estimation of amino-nitrogen, the protein nitrogen in the extract is removed by basic lead acetate, the filtrate freed from lead by sulphuric acid, and the bases precipitated by phosphotungstic acid (10%), care being taken to avoid any excess. A portion of the filtrate is freed from sulphuric and phosphotungstic acids by means of baryta; the solution is made up to a definite volume and filtered; after removal of excess of baryta with carbon dioxide the filtrate is concentrated to 50–60 c.c. at a low temperature, care being taken to maintain neutrality by periodical addition of very dilute nitric acid. The solution is finally precipitated by freshly prepared, clear mercuric nitrate solution, an excess of the reagent being avoided. The precipitate is collected, decomposed with sulphuric acid according to Kjeldahl, and the nitrogen estimated. The filtrate from the mercury precipitate contains traces of asparagine and other amides and aspartic acid which have escaped precipitation. It can be made alkaline and the liberated ammonia distilled under diminished pressure.

Phloretin; Synthesis of— and preparation of the nitriles of phenolcarboxylic acids. E. Fischer and O. Nouri. Ber., 1917, 50, 611–623.

PHLORIDZIN is hydrolysed by dilute acids to dextrose and phloretin, which latter is resolved by dilute alkalis into phloretic acid and phloroglucinol. A method devised by Hoesch (this J., 1915, 952) for the synthesis of phenol-ketones by means of nitriles has been applied by the authors to the synthesis of phloretin. The methyl ester of phloretic acid was converted into the amide by heating with methyl alcoholic ammonia under pressure; this was acetylated in order to fix the phenolic group and then converted into the nitrile by warming with phosphorus oxychloride in chloroform solution. The nitrile of acetylphloretic acid when treated in ethereal solution with phloroglucinol and zinc chloride and saturated with gaseous hydrogen chloride, according to Hoesch's method, yields a keto-imide which may be isolated in the form of its crystalline sulphate. This, on warming in aqueous solution, yields acetylphloretin, which is readily saponified by cold alkali giving phloretin in all respects identical with that prepared from phloridzin. The nitriles of *p*-coumaric acid and of gallic acid have been prepared in a similar manner from the amides of their acetyl derivatives. The product of the combination of *p*-coumaric acid nitrile with phloroglucinol was not identical with naringenin, but an isomeride differing in melting point and solubility, and lacking the ferric chloride reaction. The product obtained from phloroglucinol and the nitrile of cinnamic acid also lacked this property and is regarded as a derivative of hydrocumarin.—J. F. B.

Emodin-bearing drugs; Identification of—. W. S. Hubbard. J. Ind. Eng. Chem., 1917, 9, 518–521. (See also this J., 1917, 565.)

THE following methods for identifying aloes, cascara, rhubarb, and senna in medicinal preparations, have been in use for some time at the U.S. Bureau of Chemistry. An ether extract of the material is prepared after acidification with sulphuric or hydrochloric acid. If addition of ammonia gives a red colour (Bornträger's reaction), and phenolphthalein is absent or has been removed (see this J., Warren, 1914, 1171; Bailey, 1914,

501), a portion of the ether extract is treated with an equal volume of saturated borax solution. Aloes produce a green fluorescence, sometimes only perceptible after half an hour, rhubarb an old rose colour, cascara a brown, and senna sometimes a light brown but usually no colour at all. According to the indications of this borax test special confirmatory tests may be applied, a number of which are described and discussed. If rhubarb is present, an aqueous solution of bleaching powder, added to a portion of the ether extract, produces a red ring, or a red colour in the aqueous layer, or even a red precipitate (calcium chloride or lime gives a pink to red colour with all the drugs mentioned). If a saturated solution of ferric or ferrous sulphate is used instead of bleaching powder, a blue colour, sometimes faint but always recognisable against a white background, is formed in presence of rhubarb. No known substance besides rhubarb answers to both these tests, though samples of senna have responded to the first. A preparation of 1:8-dihydroxyanthraquinone ("Istizin"), used for the same general purposes as these drugs, gives the Bornträger reaction and that with bleaching powder, but does not respond with borax or iron salt. The brown coloration in the borax test is distinctive for cascara provided rhubarb is absent. Senna responds to none but the Bornträger test, and not always readily to that, so it cannot be identified in presence of any of the other drugs. Some colour reactions of the four drugs (ether extracts) with solutions of ammonium thiocyanate, ammonium molybdate, and uranium acetate are mentioned.—J. H. L.

Antipyrine; Determination of—. J. Bougault. J. Pharm. Chim., 1917, 15, 337–339.

THE following modifications are suggested for rendering the volumetric and gravimetric methods for the determination of this substance more trustworthy (see François, this J., 1917, 353). *Volumetric method.* Ten c.c. of a 1% aqueous solution of antipyrine is treated with 1 gm. of potassium bicarbonate and excess of N/10 iodine solution is added. After 1 hour, the mixture is acidified with 1 c.c. of acetic acid, 10 c.c. of chloroform is added, and the excess of iodine is titrated with thiosulphate solution. This method yields 99.6% of antipyrine when dealing with the pure substance. *Gravimetric method.* A quantity of about 0.5 gm. of antipyrine is dissolved in 50 c.c. of water, 2 grms. of potassium bicarbonate is added, and 20% iodine solution is run in drop by drop. The brown turbidity which forms with the addition of each drop should disappear before the next drop is added, otherwise a pasty black precipitate of iodoantipyrine mixed with iodine is formed. Colourless crystals of iodoantipyrine begin to appear soon after a slight excess of iodine has been added (this should require 30 minutes), but become blackened by the excess of iodine. After 1 hour, the mixture is decolorised by the addition of sodium thiosulphate, the precipitate is collected, washed with a few c.c. of water, dried, and weighed. The filtrate and washings from the precipitate are extracted with chloroform to recover a quantity of iodoantipyrine which remains in solution. This method yields about 99% of the antipyrine present.—W. P. S.

Acetic anhydride; Testing of—. C. E. Sage. Perfumery and Ess. Oil Rec., 1917, 8, 162–163.

IN estimating the value of acetic anhydride the total acidity is determined by direct titration with alkali hydroxide solution, and also the residual acidity after treatment with aniline in the cold, by which the anhydride is decomposed with the production of equimolecular parts of acetanilide

and acetic acid. From these two titration numbers the amount of anhydride is calculated, the remaining acidity being due to acetic acid or to acetic and butyric acids if the latter is present, which is determined by a preliminary qualitative analysis; the relative proportions of these two acids may also be calculated from the same titrations. It is suggested from the figures obtained and the large scale results when using anhydride containing butyric acid, that other anhydrides than acetic may also be present (see also H. D. Richmond, this J., 1917, 519; Radcliffe and Medofski, page 628).—B. V. S.

Ether for anaesthesia: Determination of alcohol and water in —. R. L. Perkins. J. Ind. Eng. Chem., 1917, 9, 521—523.

The author has studied the influence of 0–4% of alcohol and 0–1% of water, separately and together, on the specific gravity of pure ether at 25° C., and constructed graphs by means of which the alcohol- and water-contents of ether for anaesthesia can be found from the specific gravities before and after drying with potassium carbonate. This avoids weighing the carbonate as required by the method of Mallinckrodt and Alt (this J., 1916, 1081).—J. H. L.

Preparation of carbon suboxide from malonic acid and phosphorus pentoxide. Stock and Stoltzenberg. See VII.

PATENTS.

Acetic anhydride; Manufacture of —. H. Dreyfus, Basle, Switzerland. Eng. Pat. 100,452, May 8, 1916. (Appl. No. 6600 of 1916.) Under Int. Conv., Apr. 28, 1915. Addition to Eng. Pat. 100,450 (this J., 1917, 611).

In the process described in the principal patent, the acetic anhydride should be distilled off *in vacuo* at temperatures below 150° C., otherwise it is partially decomposed by the free sulphur with formation of acetic acid.—F. Sp.

Liquid pharmaceutical preparations: Method of solidifying —. C. A. Cofman-Nicoresti, Snarebrook. Eng. Pat. 105,949, May 1, 1916. (Appl. No. 6198 of 1916.)

SOLUTIONS of potent drugs in alcohol or liquid paraffin are solidified by the addition of salts of the higher fatty acids, for the purpose of manufacturing suppositories, pessaries, bougies, etc. *Example.* To 100 c.c. of an alcoholic solution of iodine is added 5–6 grms. of sodium stearopalmitate or animal soap. The mixture is heated above 50° C. until the soap is incorporated, and then poured into moulds and allowed to cool. Solidification may be accelerated by adding 1 grain of hard paraffin or wax to 1 oz. of the solution. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 961 of 1892, 12,446 of 1893, and 2343 of 1901; this J., 1893, 31; 1901, 495.)—F. Sp.

Chlorinating [hydrocarbons]; Process of — and *products thereof.* G. Mersereau, New York. Assignor to Chemical Development Co. U.S. Pat. 1,221,485, May 1, 1917. Date of appl., Mar. 27, 1913.

PETROLEUM oil is cracked to yield a mixture of unsaturated hydrocarbons. After separation of "condensable matter," the residual gas is treated

with chlorine in successive stages at increasing temperatures, *e.g.*, one treatment may be at 15° C., and another at 100° C.—F. Sp.

Tobacco: Method of dehydrating and curing —. G. H. Benjamin, New York. U.S. Pat. 1,224,703, May 1, 1917. Date of appl., Sep. 23, 1914.

TOBACCO is dehydrated and cured by heating it in a current of hot air to 110° C. for 1–2 hours, then to 120° C. for 2–5 hours, and then to 140° C. until the original moisture content is so reduced as to permit endosmotic action through the cell membrane but is insufficient to react with the enzyme of the tobacco to produce fermentation or mould. Finally the tobacco is heated to 200° C. for 2–10 hours, with or without exposure to electric light, in order to develop the aromatic character of the essential oils of the tobacco, and progressively to change its colour.—F. Sp.

Hog-cholera antitoxin; Process of treating —. J. Reichel, Philadelphia, and H. Werner, Norwood, Pa., Assignor to H. K. Mulford Co., Philadelphia, Pa. U.S. Pat. 1,221,860, May 1, 1917. Date of appl., Jan. 19, 1917.

HOG-CHOLERA antitoxin treated with the usual preservatives, *e.g.*, phenol or tricresol, is mixed with not more than 0.5% of an aldehyde, *e.g.*, formaldehyde, and heated for a sufficient length of time to kill the foot-and-mouth disease virus. The addition of the aldehyde prevents coagulation and produces sterility. The heating process may be carried out in the vessels in which the preparation is finally to be sold.—F. Sp.

Camphor; Production of concentrated solutions of — *in fatty oils, stable in the cold.* J. D. Riedel. A.-G. Ger. Pat. 297,084, Oct. 28, 1914.

CASTOR oil or the fatty acids from castor oil are added to olive oil or similar fatty solvents of camphor, in order to increase their solvent power. More concentrated solutions of camphor for therapeutic use can thus be obtained which do not deposit camphor in the cold.—F. Sp.

p-Aminophenyl salicylate; Manufacture of a bromo-derivative of —. I. Abelin, Berne, and S. Lichtenstein-Rosenblat, Berlin. Ger. Pat. 297,243, Dec. 30, 1915. Addition to Ger. Pat. 291,878 (this J., 1916, 867).

p-AMINOPHENYL salicylate is treated with an α-bromodithylacetyl halide, instead of an α-bromo-isovaleryl halide as in the original patent. The new product has a stronger sedative, antirheumatic, and soporific action, and is tasteless.—F. Sp.

Process of transforming mineral oils [into terpenes]. U.S. Pat. 1,224,787. See IIa.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Lithographic key on zinc and aluminium; Photographic production of a —. J. I. Crabtree, Comm. No. 48 from Eastman Kodak Research Laboratory. J. Franklin Inst., 1917, 183, 635–636.

A PRELIMINARY treatment is given with a 1% solution of citric acid for zinc, and oxalic acid for aluminium, followed by quick drying. The plate is then coated with a sensitising mixture of 3 parts of a solution of 30 grms. of ferric ammonium citrate (brown scales) in 150 c.c. of water with 1 part of a solution of the same strength of potassium ferriyanide. After exposure the image is developed in water or in a solution of 0.5% potassium ferriyanide and 0.5% citric acid (for zinc) or

oxalic acid (for aluminium). With this treatment there is no danger of the final image washing off the metal plate.—B. V. S.

Negatives and prints; Scientific washing of——. A. W. Warwick. From American Photography. Brit. J. Phot., 1917, 44, 261—4.

THE hypo solution retained by a fixed photographic negative or print is partly on the surface and partly in the film, and in the case of a print partly in the base. In subsequent washing by changes of water, the former, the "surface solution," will naturally obey Bunsen's Rule,

$$1/A = \left(\frac{v}{v+V} \right)^n \text{ where } 1/A \text{ is the fraction of hypo}$$

after n washings, v and V being the volumes respectively of the residual solution and the added water for each washing. The latter, or "absorbed solution," follows the same rule only if sufficient time is allowed at each washing for the attainment of equilibrium, which takes about 5 mins. A factor, K , was determined experimentally for the departure from the rule for a certain set of conditions, by determining the amounts of hypo left in and on the film after each washing. In the case of N.C. film K varied from 1.37 to 1.04, with an average of 1.25 for the

$$\text{logarithmic form of the rule } n = K \frac{\log A}{\log \left(1 + \frac{V}{v} \right)}$$

The conditions for plates are similar to those for N.C. films except that there is less hypo to remove; for prints the difference in the rate of obtaining equilibrium in the base as compared with the film complicates the problem. In the case of washing in running water, assuming that the conditions are such as to keep the water over the film constantly free from hypo the rule $\log A = Kt$ applies, where A is as before, t is the time (in minutes), and K an experimentally determined factor. For an ordinary tank washer for plates K was found to be 0.129 and for Windoes' shelf washer (Amer. Phot., Apr., 1914) 0.14. For prints K drops to about 0.65. A value of 1/50000 for A is suggested as being quite safe and this is reached in about 5 washes of 900 c.c. each for 6 mins. for a $5'' \times 4''$ N.C. film, in about 35 mins. for a shelf washer, and a little longer for a tank washer for plates, and in about 72 mins. in a tank washer for prints.

—B. V. S.

PATENTS.

Sulphur acids from fixed photographic media; Process of eliminating salts of the weak——. S. H. Weinhandler, New York, and J. S. Simson, Philadelphia, Pa. U.S. Pat. 1,224,981, May 8, 1917. Date of appl., Sept. 9, 1916.

THIOSULPHATES or salts of other weak sulphur acids are eliminated by the action of hypochlorite, which may be produced by the electrolysis of a bath of common salt containing the negatives or prints to be treated. By working in strongly alkaline solution the gelatin is rendered porous and the action of the hypochlorite on the sulphur salts extends right through the film before bleaching of the image sets in. Easily soluble salts are formed which are removed by washing with water.—B. V. S.

Colour photography. H. Hess, Assignor to Hess-Ives Corporation, Philadelphia, Pa. U.S. Pat. 1,225,246, May 8, 1917. Date of appl., Mar. 26, 1914.

IN the preparation of multicolour prints from a multicolour diapositive, a series of negatives is taken by exposure through the diapositive to lights of various suitable colours. Colloid relief

prints are taken from these negatives, stained in colours complementary to those used in taking the negatives, and combined in register.—B. V. S.

Photographic images; Methods of bleaching and dyeing——. Brewster Film Corporation, Assignees of H. Miller, New York. Eng. Pat. 100,098, Feb. 2, 1916. (Appl. No. 1,560 of 1916.) Under Int. Conv., Feb. 26, 1915.

SEE U.S. Pat. 1,214,940 of 1917; this J., 1917, 403.

XXII.—EXPLOSIVES; MATCHES.

Guncotton; Sand fusions from [exploding]——. C. E. Munroe. Amer. J. Sci., 1917, 43, 389—390

A CAST-IRON shell with walls $1\frac{1}{2}$ in. thick, after being charged with 3 slabs of wet guncotton, one dry primer, and an igniting charge of 4 oz. gunpowder, was buried to a depth of 3 feet in compact sea-sand. On firing, the base plug of the shell was projected to a short distance and the shell broken into large fragments which remained embedded. In some cases no crater was formed, the wet guncotton was incompletely burned, and the surrounding sand was fused or sintered together in the form of a tube resembling *fulgurites* (i.e., vertical tubes with fused walls formed in sand by the action of lightning).—J. N. P.

Fulminates and azides; New——. L. Wöhler and F. Martin. Ber., 1917, 50, 586—596. (See also this J., 1917, 570.)

IN addition to sodium fulminate, the hitherto unknown simple cadmium, thallous, and cuprous fulminates have been prepared by the action of an amalgam of the metal on silver or mercury fulminate in presence of ethyl or methyl alcohol and precipitation of the new fulminate with ether. Treatment with the amalgam is carried out in a rubber-stoppered bottle in a shaking machine, not more than 1—2 grms. of mercury or silver fulminate being treated at one time, and all the operations being performed in an atmosphere of dry hydrogen. Cadmium amalgam is prepared by electrolysis of the sulphate with mercury cathode; the amalgam containing 20% of cadmium is washed with water and methyl alcohol and lastly with methyl alcohol distilled over barium oxide. Two grms. of mercury fulminate with the addition of 30 c.c. of anhydrous methyl alcohol, cooled by ice, is shaken with the amalgam for about 25 mins. until a test of the filtered solution shows no reaction of mercury with stannous chloride. The product is passed through a filter into dry ether, in a current of hydrogen, and the washing of the fulminate with ether is conducted with the same precautions. After drying *in vacuo* the fulminate still retains about 2% of methyl alcohol from which it is not completely freed even by heating at 55° C. over phosphorus pentoxide *in vacuo* for 24 hours. The analysis of the soluble fulminates is made by Vollhard's method, in methyl alcoholic solution, using alcoholic silver nitrate. Cadmium and thallium fulminates are soluble and subject to hydrolytic decomposition in presence of moisture; cuprous fulminate is insoluble and can be prepared by shaking the amalgam with mercury fulminate in presence of water in an atmosphere of hydrogen. Soluble azides of the heavy metals, of normal composition, have been prepared by the action of azoimide (hydrazoic acid) on the carbonates or basic azides in presence of ether. Normal azides of nickel, cobalt, zinc, and manganese are described. The azoimide may be prepared without danger by gradually introducing 5 grms. of finely powdered sodium azide into a mixture of 100 c.c. of ether and 2 c.c. of concentrated sulphuric acid.

shaking, and filtering off the sodium sulphate. The treatment with the metallic carbonates requires 3–4 days in the shaking machine; the material must be dry and very finely powdered. The end of the reaction is indicated by solubility in water; the suspended azide is filtered off and washed with ether. In the case of manganese it is necessary to start from the basic azide because the reaction proceeds too slowly with the carbonate; basic zinc azide may also serve for the preparation of the normal zinc azide. Nickel azide is particularly sensitive to rubbing and explodes violently. The solutions of all these normal azides are readily hydrolysed giving basic deposits. Ferric and chromic azides of normal composition could not be obtained.—J. F. B.

Toluols containing paraffins; Process of nitrating — B. J. Flürscheim, Fleet, England, Assignor to Aetna Explosives Co., Inc., New York, U.S. Pat. 1,225,321, May 8, 1917. Date of appl. Mar. 23, 1916.

NITRATION is carried out in two stages, the mononitrotoluene first formed being separated from the paraffins by solution in about an equal volume of sulphuric acid.—B. V. S.

[Paraffin] wax tapers for matches or other purposes; Manufacture of — W. H. Dixon, London, Eng. Pat. 106,071, Jan. 18, 1917. (Appl. No. 929 of 1917.)

A COMPOSITION for wax tapers for matches consists of paraffin wax of m.p. 110°F . (60°C .) 400 parts, aluminium stearate 25 parts, gum dammar 10 parts, calcium sulphate 75 parts. When artificial thread is used, zinc or magnesium stearate or palmitate may be substituted for aluminium stearate. The calcium sulphate may be replaced by talc, wood dust, or cork dust. The paraffin wax is heated to a temperature slightly above its melting point and the other ingredients mixed and then added as a dry powder.—W. F. F.

XXIII.—ANALYSIS.

Viscosity of very viscous media; Measurement of the absolute — S. E. Sheppard, J. Ind. Eng. Chem., 1917, 9, 523–527.

THE rate of fall of a spherical body through a liquid, after uniform velocity has been attained, furnishes data for the calculation of the absolute viscosity of the liquid, in accordance with Stokes' law, thus: $K(\text{viscosity}) = 2R^2T(s - s')g/9S$, in which R is the radius and s the density of the spherical body, s' is the density of the liquid, g the acceleration due to gravity, and T is the time taken for the body to fall through a vertical distance S (all values being expressed in c.g.s. units). In the author's experiments steel ball bearings ($\frac{1}{8}$, $\frac{3}{16}$, and $\frac{1}{4}$ in. diam.) were allowed to fall axially in glass cylinders 40 cm. high, filled with the liquid and kept at $20 \pm 0.2^{\circ}\text{C}$. by water jackets. The time taken for a ball to fall between two fixed marks distant about 10 cm. from the top and bottom of the liquid column respectively, was measured to within $\frac{1}{2}$ sec. with precautions against parallax. To correct for the impeding influence of the walls of the cylinder it was found necessary to substitute for T in the above equation $T - C(r - 1)^2$, in which C is a constant and r is the ratio of the diameter of the cylinder to that

of the ball. The values for K thus obtained required a further correction for the ratio of the height of the liquid column to the radius of the ball. With these corrections the method is considered satisfactory for very viscous media.

Palladium-gold crucibles as platinum substitutes. Met. and Chem. Eng., 1917, 16, 533.

AN alloy of palladium and gold known as "Palau," which has been prepared as a substitute for platinum, has the surface colour of pure palladium and is similar to, but slightly darker than, hammered platinum. Tests at the U.S. Bureau of Standards showed that a crucible formed of the alloy is not so easily deformed as one of pure platinum though not so rigid as a crucible made of platinum with about 8–10% rhodium. The sp. gr. of the alloy is 17.22 and the melting point 1370°C . The E.M.F. against pure platinum is 8.5 millivolts at 960°C . and 7.2 millivolts at 860°C . A crucible of the alloy was heated to 1200°C . in a furnace free from metal vapours, for two periods of 4 hrs. each, and weighed before and after each heating. The weighings to determine the loss due to heating were followed by treatment for 5 mins. with boiling hydrochloric acid (HCl to HCl_2O) and the loss in weight due to the acid treatment was determined. The solutions obtained from this crucible contained less than 0.01 mgrm. of iron. The tests indicated that the "Palau" crucible, as far as resistance to loss on heating to 1200°C . is concerned, is superior to platinum containing about 2.4% iridium. The comparative freedom from iron is an improvement over most platinum ware now in use. The alloy compares favourably with platinum in resistance to hydrochloric, nitric, hydrofluoric, and sulphuric acids, ferric chloride and sodium hydroxide solutions, and fused sodium carbonate. The "Palau" crucible is not as suitable for potassium pyrosulphate fusions as platinum. Both this alloy and platinum are seriously attacked by fused sodium carbonate and nitrate mixture, though the "Palau" crucible is the more resistant.—J. N. P.

Mercury still [for laboratory use]. L. H. Duschak and S. O. Spencer. J. Phys. Chem., 1917, 21, 311–313.

MERCURY is placed in the cup, A, with a reserve supply in the reservoir, B, by which the level in the cup is automatically maintained constant.

The horizontal branch of the three-way stopcock, C, is joined to a water aspirator or other suction device whereby mercury is raised in the annular space between the extended neck of the flask, D, and the condenser tube within. This flask, which may be of soda lime glass, although Pyrex or Jena glass is preferable, will ordinarily have a capacity of 1000 to 1500 c.c., and is supported by a strong wooden clamp (not shown), which grips the neck just below the gas burner. The elevation of the flask above the cup should be such that the difference in mercury levels will be 20 to 30 mm. less than the barometric pressure. A stream of air is adjusted to enter through the capillary tip at E, so that several bubbles per

second pass up through the mercury in D; a plug of cotton wool prevents dust from altering the size of the orifice. The rate of distillation is so regulated that the condensation of the mercury vapour in the upper part of the tube, F, is practically completed 10 to 15 cm. above the mercury level in the cup, A. From time to time it is necessary to remove the flask, D, in order to wash out the accumulated impurities with nitric acid. As shown in the sketch, the still may be heated by gas, using a piece of "nichrome" gauze and an asbestos hood, or by an electrical heater, and a rate of distillation of about 750 grms. per hour obtained. The presence of the small partial pressure of oxygen causes oxidation of the common metals contaminating the mercury, which are thus separated more effectively than by ordinary distillation.

—J. N. P.

Yellow mercuric oxide as a standard in alkali-metry.

G. Ince. *Z. anal. Chem.*, 1917, **56**, 177—191.

YELLOW mercuric oxide is a trustworthy substance for use in standardising acid solutions; it is readily obtained in a pure state, is free from water of crystallisation, and is not hygroscopic. Its use depends on the reaction:

At least 9 mols. of potassium iodide must be added for each mol. of mercuric oxide; in practice, it is advisable to add a somewhat larger proportion of iodide, for instance, 10 c.c. of 60% potassium iodide solution to 0.4 gm. of the oxide. As soon as the oxide has dissolved in the iodide solution, the mixture is titrated with the acid solution to be standardised, using methyl-orange, phenolphthalein, or methyl-red as indicator. The yellow mercuric oxide as bought is usually pure, but if desired it can be made by dissolving 100 grms. of mercuric chloride in 1 litre of warm water, cooling the solution, and then adding 625 grms. of 6.4% sodium hydroxide solution, the mixture being well stirred during the addition of the alkali. The precipitate is collected, washed until the wash-water is no longer alkaline to phenolphthalein, then air-dried and stored in black glass bottles.—W. P. S.

Analysis: Electrolytic— with small platinum electrodes. F. A. Gooch and M. Kobayashi. *Amer. J. Sci.*, 1917, **43**, 391—394.

A ROTATING electrode was made of a piece of platinum gauze, 1.2 cm. square, in the central meshes of which the tapered end of a lead glass rod was fused. Electrical connection was made by means of a doubled and twisted platinum wire, 0.03 cm. in diameter, wound about the glass rod and welded to a copper wire which during rotation made a sliding contact with a shaft connected with one of the poles of the source of current. The stationary electrode consisted of a strip of thin platinum foil, 5 cm. \times 0.5 cm., welded to the connecting wire by means of which it was suspended against the sides of a thin glass beaker of about 120 c.c. capacity. In order to collect particles which became detached on account of the non-adherent nature of the deposit resulting from the high current density on the small electrode surface, a small filtering tube was made by fusing the flanged end of a lead glass tube to a small disc of platinum gauze and coating the disc with a filtering mat by dipping it in an emulsion of asbestos and applying suction. The beaker, both electrodes, and the filtering tube, which may be ignited without difficulty, were first dried and weighed together, the total weight amounting to about 20 grms. The electrode, which was arranged to rotate at 600 revs. per min., was suspended vertically in the beaker containing the solution to

be analysed. After electrolysis, the liquid remaining was drawn off by suction through the filtering tube and the washed beaker, electrodes, and filtering tube were dried and again weighed together. The copper in an electrolyte of 100 c.c. volume containing 0.5 gm. of crystallised copper sulphate and free sulphuric acid, was completely precipitated within an hour by means of a current of about 0.2 amp. (15 amps. per sq. dm.) with a potential of 4 volts between the electrodes. It was found necessary to allow the cathode deposit, after superficial washing, to stand for a few minutes in distilled water in order to remove occluded sulphuric acid. With nickel, 0.1 gm. of the metal was deposited completely in 1½ hrs. from 100 c.c. of solution containing ammonia and ammonium sulphate by means of a current of 0.8 to 1 amp. at 10 to 12 volts. For the determination of lead, the electrolyte consisted of lead nitrate and 30 c.c. of concentrated nitric acid in 100 c.c. of solution, when lead peroxide is deposited on the electrode on arranging this as anode and rotating at a rate of 150 revs. a minute. As the content of lead is reduced, the peroxide deposit becomes more adherent, and it was found necessary to continue the electrolysis until no detached peroxide, which is gradually redissolved by the nitrous acid present in the electrolyte, remained in suspension in the solution. Twenty minutes before the termination of the electrolysis, urea was added to destroy the nitrous acid and prevent the solvent action of the electrolyte on the deposit on stopping the current. The electrolysis was continued for two hours with a current of 3 to 4 amps. at 5 to 7 volts. The beaker, electrodes, filtering tube, and deposit were finally dried at 200° C. and weighed.—J. N. P.

Water; Determination of— by distillation. A. A. Besson. *Chem.-Zell.*, 1917, **41**, 346—347.

AN apparatus is described in which water can be determined in such substances as soap, cheese, etc. From 5 to 15 grms. of material is heated in an oil bath in a Kjeldahl flask, together with about 200 c.c. of xylol or paraffin oil. The water and the vapour of the distilling medium pass into a Soxhlet apparatus with a graduated lower portion, in which the water can be collected and measured. —W. H. P.

XXIV.—MISCELLANEOUS ABSTRACTS.

Copper ferrocyanide membrane: Selective properties of the — F. Tinker. Proc. Roy. Soc., 1917. A. 93, 268—276.

COLLOIDAL copper ferrocyanide was prepared by

mixing solutions of potassium ferrocyanide and copper sulphate, centrifuging and washing with water to remove the excess of the dissolved salts, and again centrifuging. By partially drying, the precipitate was prepared with a varying content of water and then shaken with sugar solutions for two days, at a temperature maintained at 15° C. Changes produced in the concentration of the sugar through the absorption of water by the copper ferrocyanide, or its liberation from the moist precipitate to the solution, were determined by polarimetric measurement. Equilibrium in the partition of water between the solution and the precipitate was attained within a few hours. The amount of water absorbed or retained by 100 grms. of ferrocyanide when placed in solutions of sucrose of varying concentrations in 100 grms. of water was found to be approximately constant for different samples of the ferrocyanide and, down to a certain limiting value, to decrease as the concentration of sugar increased. With pure water, 30 grms. was absorbed and with a sugar solution of 60% concentration and above, a constant value of 13 to 14 grms. was approached. This result indicates that the ferrocyanide forms the hydrate, $\text{Cu}_2\text{Fe}(\text{CN})_6 \cdot 3\text{H}_2\text{O}$, which corresponds to a moisture content of 15.7 grms. of water per 100 grms. of dry ferrocyanide. With more dilute solutions, the excess of water above this amount absorbed by the ferrocyanide can only be attributed to adsorption on the surface of the colloidal particles, as there was found to be no simple relation between the amount of water taken up and the concentration of sugar, and by varying the weight of ferrocyanide in a solution of given strength the amount absorbed was not a constant as it should be if the water were either dissolved or hydrate water. In the osmotic action of the copper ferrocyanide membrane, the colloidal particles of the hydrated compound are consequently to be regarded as adsorbing water selectively from sucrose solutions, in inverse proportion to the concentration of the sugar, without taking up the sugar to any appreciable extent. The permeability of the membrane is thus due to the pressure of adsorbed moisture, which is greater on the water side than on the solution side, resulting in a continual flow across the membrane as long as there is a concentration difference on the two sides. —J. N. P.

Books Received.

INDUSTRIAL RESEARCH IN THE UNITED STATES. By A. P. M. FLEMING. H.M. Stationery Office. 60 pages, 9½ × 7¼ in. Price 1s. (See p. 030.)

THE CHEMISTRY OF DYESTUFFS. By M. FORT and L. L. LLOYD. Cambridge University Press, Fetter Lane, London, E.C. 311 pages, 8 × 5½ in. Price 7s. 6d.

FOLLOWING a brief historical introduction, the authors give a short account of the distillation of tar and the conversion of tar products into intermediate compounds. Chapters on the application of dyestuffs and on colour and constitution are followed by descriptions of the principal dyes classified according to constitution. The descriptions are clear and concise, and the book is well printed and appears to be quite suitable for the purpose for which it was written, namely, as a manual for students of chemistry and dyeing.

PROHIBITED EXPORTS.

An order-of-Council, dated 22nd June, 1917, orders that the Schedule to the Proclamation, dated 10th May, 1917 (see this J., 1917, 523), prohibiting the exportation from the United Kingdom of certain articles to certain or all destinations,* should be amended as follows:—

The following headings are deleted:—(C) Asphalt; (C) Asphalt, coal tar; (C) Bitumen, liquid or solid; (B) Paraffin, liquid medicinal; (B) Ferro-manganese; (A) Ferro-tungsten; (C) Glue, osseine and concentrated size, fish glue, isinglass, finings and other kinds of gelatin; (C) Iridium and its alloys; (A) Ivory, vegetable; (B) Lubricants and articles and mixtures containing lubricants; (B) Mica, mica splittings, mica powder, micaite, and articles made from, and insulating materials containing, them; (B) Mineral jellies; (A) Molasses; (B) Motor spirit (except benzol); (B) Oil fuel, except oil fuel allowed by the Commissioners of Customs and Excise to be shipped; (B) Oil fuel, shale; Oils, vegetable, the following, and articles and mixtures containing such oils—(B) All other vegetable oils except essential oils; (C) Osmium and its alloys; (C) Palladium and its alloys; (B) Paraffin oil; (B) Petroleum, fuel oil; (B) Petroleum, lighting oil; (B) Petroleum, gas oil; (B) Petroleum spirit and articles containing petroleum spirit; (C) Petroleum and its products not otherwise specifically prohibited; (C) Yeast and articles, mixtures, and preparations containing yeast; (C) Rhodium and its alloys; (C) Ruthenium and its alloys; (A) Tallow; (B) Turpentine substitute, and articles containing turpentine substitute; (B) Varnishes containing shellac, oil, turpentine or turpentine substitute.

The following headings are added:—(B) Asphalt; (B) Asphalt, coal tar; (B) Bitumen, liquid or solid; (C) Adrenaline; (C) Atypin; (C) Aloe juice; (C) Amylene; (C) Anchusa; (C) Anchusin; (C) Apiol; (C) Chlorides, metallic and metalloidal, not otherwise prohibited; (B) Citrates; (C) Digitaline; (C) Ergotine; (C) Eryngo; (C) Eserine; (C) Exalgin; (C) Hydrastis canadensis; (A) Hydrocyanic (prussic) acid and solutions thereof; (A) Lactates, not otherwise prohibited; (A) Lactic acid; (C) Liquorice roots and juice; (C) Lithium compounds; (C) Lycopodium; (A) Manna; (A) Mannite; (A) Paraffin, liquid medicinal; (C) Pepsin; (C) Peptone; (C) Pilocarpine; (A) Potassium carbonate, and mixtures containing potassium carbonate; (C) Saffron; (B) Sodium peroxide; (C) Sulphocyanides, not otherwise

prohibited; (C) Sulphorinates; (C) Tannalbin; (C) Tannigen; (C) Vaccines; (C) Valerianates, not otherwise prohibited; (C) Valerianic acid; (A) Ferro-manganese; (B) Glue, osseine and concentrated size, fish-glue, isinglass, finings and other kinds of gelatin; (B) Gum fragacanth; (C) Insecticides, not otherwise prohibited; (C) Iridium and its alloys, and manufactures containing iridium; (A) Ivory, vegetable, and manufactures thereof; (C) Lithium; (A) Lubricants, mineral, and articles and mixtures containing mineral lubricants; (B) Lubricants not otherwise specifically prohibited, and articles and mixtures containing such lubricants; (A) Mica block and mica splittings; (B) Mica sheets, mica waste, mica powder, micaite, and articles made from and insulating materials containing mica in any form; (A) Mineral jellies; (A) Molasses, and articles, mixtures, and preparations containing molasses; (A) Motor spirit; (A) Oil fuel, except oil fuel allowed by the Commissioners of Customs and Excise to be shipped for use on board the exporting ship; (A) Oil fuel, shale; Oils, vegetable, the following and articles and mixtures containing such oils—(A) Linseed; (B) All other vegetable oils, not otherwise prohibited; (C) Osmium and its alloys, and manufactures containing osmium; (C) Palladium and its alloys, and manufactures containing palladium; (A) Paraffin oil; (A) Petroleum fuel oil; (A) Petroleum gas oil; (A) Petroleum lighting oil; (A) Petroleum spirit, and articles containing petroleum spirit; (A) Petroleum and its products not otherwise specifically prohibited, and mixtures thereof; (A) Levulose; (A) Milk sugar (lactose); (A) Yeast, and articles, mixtures, and preparations containing yeast; (C) Rhodium and its alloys, and manufactures containing rhodium; (C) Ruthenium and its alloys, and manufactures containing ruthenium; (C) Silicon; (A) Tallow and articles, mixtures, and preparations containing tallow; (C) Tar, oil, not otherwise specifically prohibited; (A) Tungsten alloys; (A) Turpentine substitute, and articles containing turpentine substitute; (C) Vanillin; (B) Varnishes containing shellac, oil, or turpentine not otherwise prohibited.

CASTOR OIL AND PALM OIL PRICES. MINISTRY OF MUNITIONS ORDER, JUNE 19TH, 1917.

The Minister of Munitions hereby orders that as on and from June 29th the maximum prices specified in the Schedule to this Order for purchases and sales of and dealings in castor oil and palm oil shall be substituted for those specified in the Schedule to the Order of the 9th May, 1917 (see this J., 1917, 523), for purchases and sales of and dealings in such oils and the Orders of the 1st May (this J., 1917, 497) and 9th May, 1917, shall have effect in all respects as if the prices specified in the Schedule to this Order had originally been specified in the Schedule to the Order of the 9th May as the maximum prices for purchases and sales of any dealings in castor oil and palm oil.

SCHEDULE.

	Per ton.
	£ s. d.
Castor oil (pharmaceutical) ..	88 0 0
Castor oil (ordinary) ..	80 0 0
Palm oil (bleached) ..	50 0 0
Palm oil (unbleached) ..	11 0 0

The above prices are for oil net naked ex ship, mill or warehouse in the United Kingdom.

* The prohibition of exports is as follows:—

Goods marked (A), to all destinations;

Goods marked (B), to all ports and destinations abroad other than ports and destinations in British Possessions and Protectorates;

Goods marked (C), to all destinations in foreign countries in Europe and on the Mediterranean and Black Seas, other than France and French Possessions, Russia, Italy and Italian Possessions, Spain and Portugal, and to all ports in any such foreign countries, and to all Russian Baltic ports.

Packages may be charged extra at current market rates but not exceeding £1 per ton on the oil, or (in the case of castor oil sold for any special purpose in special packages) such higher sum per ton (if any) as may from time to time be authorised to be charged by the Controller of oils and fats.

Edinburgh Section.

Meeting held on Tuesday, December 12th, 1916.

PROF. JAMES WALKER IN THE CHAIR.

THE PURCHASE AND CONTROL OF FACTORY SUPPLIES.

BY B. D. PORRITT, B.Sc. (LOND.), F.I.C.

Many of the more important industrial supplies are limited in variety, fairly uniform in quality, and subject to market control. The organisation necessary to purchase and control supplies of this kind, of which plantation rubber may be cited as an example, are of a simple character, limited to the official responsible for the duty—generally known as the buyer—and the staff necessary for ascertaining the requirements of the factory, certifying the deliveries being correct in quantity, and conducting the clerical work of the purchasing department. Under such conditions little need is likely to be experienced for scientific assistance. When, however, as is generally the case, the factory supplies comprise materials liable to wide variations in quality, due either to the nature of the raw materials or to differences in the processes employed in their preparation, the problem confronting the purchaser is much more complicated, since price is no longer the sole consideration.

The discussion which follows will be limited to instances in which improvements in either the price or the quality of supplies may be effected by judicious purchasing combined with efficient laboratory examination, and the conditions which obtain in a factory devoted to the manufacture of rubber goods will be selected for special consideration.*

A manufacturer will desire his supplies to be of uniform and satisfactory quality. The materials, moreover, will have to be purchased at prices equal to or less than those paid by rivals. The manufacturer will, in addition, require his stocks to be maintained at the lowest quantity consistent with safety.

The control of factory supplies should be divided between three officials, namely, the buyer, responsible for the price and the source of the material; the stores superintendent, answerable for the quantity ordered and the correctness of the delivery; and the factory supplies chemist, entrusted with the duty of determining the standard of quality to be ordered and the suitability of the material supplied.

One of the first steps to be taken in developing and systematising such a factory supply organisation should be the creation of a self-contained department in which the deliveries of goods can be checked, tested, and, if satisfactory, stored until required by the manufacturing departments. In order that the Costing and Sales Department may issue their price lists and quotations, it is customary in most businesses for the Purchasing Department to issue yearly or half-yearly statements giving the prices at which standard materials

will be supplied by the store to the factory. This procedure will also furnish an indication of the efficiency of the work of the buyer and the stores superintendent.

In addition to specifying the quality to be ordered and verifying the correctness of the material supplied, the laboratory will be required to assist the buyer in selecting suitable sources of supply by examining and reporting on the samples received.

In order that the buyer may be at liberty to concentrate his attention on the study of the markets, he should be as free as possible from the distractions of routine clerical work and the petty enquiries and complaints which are inevitable in a large factory. To the stores superintendent, therefore, should be delegated such tasks as seeing that contract deliveries are coming forward to time, investigating complaints and the like.

The duties of the laboratory in connection with the purchase and control of supplies may be said to fall under the following headings:—

(1) The standardisation of all the more important supplies together with the elimination of any unnecessary, unsatisfactory, or unduly expensive materials, and the reduction of the number of standards to the minimum consistent with factory efficiency.

(2) The testing of deliveries from contractors to ensure conformity to the specified standard of quality.

(3) The examination of samples submitted to the purchasing department by would-be suppliers.

Until the work included under the first heading is complete, that falling under the second and third categories obviously can be carried out only to a limited extent. Unfortunately, the amount of work involved in standardising the factory supplies generally will be very considerable, and in some instances three or four years may elapse before every item has been satisfactorily investigated and adjusted. Though the system has to be introduced gradually, its advantages, however, should begin to be experienced as soon as the more important materials have received attention. In order to hasten the completion of the preparatory work the factory supplies chemist should be relieved from the responsibility of devising the necessary analytical and physical tests, which should be assigned to the research section of the laboratory.

The first step towards the standardisation of the supplies should consist in compiling statements showing the materials employed in each department of the factory, the quantity used, the price paid, together with particulars of the purposes for which each is used, and any information available regarding past or present manufacturing troubles attributed to particular supplies. From these lists a summary can be prepared showing all the departments which are interested in particular supplies, together with the total annual cost of each item.

This preliminary work having been accomplished, a conference between the members of the staff responsible for the supplies—the buyer, the factory supplies superintendent, and the chemist, who will together constitute what may be termed the Factory Supplies Committee—should be held in order to discuss the results and determine the order in which the items should be investigated.

Having already obtained all the information available from the factory, the laboratory staff can proceed to elaborate their methods for the analysis of the particular supply. The results will be specially interesting when the material is one supplied under some fancy trade name: in such cases the price will generally be found to be far higher than is justified by the actual composition of the substance. When these analyses have

* "Some Notes on the Raw Material used by the Rubber Manufacturer." This Journal, 1916, p. 986.

been completed, it will remain to consider whether the material is satisfactory in quality and price or whether some other less expensive substance could not be substituted with advantage. At this stage, therefore, it will probably be necessary for the purchasing department to send out inquiries for quotations and samples to a number of suppliers. In certain cases, however, before sending out inquiries, it may be advisable to consider whether it would be advantageous for the firm to produce or manufacture the particular material themselves. Such a proceeding will, in general, be profitable only on a large scale which will enable the plant to be kept running constantly at full capacity or with a view to preventing the disclosure of works' processes or plant. Most of the large rubber works manufacture their own "reclaimed" rubber, and a few of the largest possess their own rubber plantations and weave their own fabrics. The advent of the organic "accelerator" of vulcanisation may induce some rubber manufacturers to undertake the manufacture of organic chemicals in order to prevent the disclosure of their special "compounds" to competitors.

The samples and quotations received by the Purchasing Department as a result of its inquiries should be carefully numbered and all the available information recorded for reference. The samples should then be sent to the laboratory for examination with all these particulars. Those thought promising for various reasons by the buyer should be indicated for special attention. The examination of this range of samples, probably differing considerably in quality, will enable the laboratory to perfect their analytical methods and to form an opinion regarding the standard which is satisfactory for factory use. Such conclusions should be confirmed, first by small scale factory experiments, and secondly, if successful, by manufacturing tests on a larger scale. When as a result of this preliminary work a material has been selected as a standard by the Factory Supplies Committee, the laboratory can proceed to elaborate their routine methods for the examination of samples and the control of supplies respectively. At the same time a specification can be drawn up for the use of the Purchasing Department.

In compiling a "Reference Book" for the use of the factory supplies chemist, each individual supply should be considered very thoroughly and all the information obtained during the preliminary investigations just considered should be recorded for future use. It should, therefore, be possible to ascertain at a glance the departments making use of a particular material and the purpose to which it is put in each. Important references in scientific and technical literature should be noted, together with information regarding the source of the supply or the methods employed in its manufacture which may serve as a guide either to the impurities or defects to be sought during testing or to the conditions likely to influence its price. Full details should be given both of accurate methods of analysis and of the more rapid tests designed to verify the quality of the deliveries received from contractors. Finally the specification or guarantee to which such deliveries will be required to conform should be included, together with the average tests or analyses obtained on the standard supply.

As some of the information in such a complete record is likely to be of a confidential nature, a "Laboratory Method Book" should be prepared for the use of the junior staff and unqualified assistants carrying out the routine work of the laboratory, containing merely the methods employed for examination of the supplies, together with the specifications.

A specification must be regarded merely as a guide to the contractor as to the quality of the

finished article desired and not as an instruction as to how he should carry on his business. Consequently, while it should give clear and concise information regarding the usage to which the material will be subjected, the results desired, and the tests to which it will be submitted, the nature of the raw materials to be used and the methods of manufacture which should be adopted in order to secure a satisfactory result should be left as far as possible to the judgment and experience of the contractor. Any departure from this procedure will, in the event of the goods supplied proving defective in use, largely relieve the contractor from responsibility. Whenever possible specifications should be submitted to a reputable supplier for criticism before they are definitely passed as satisfactory. The adoption of a specification based on an existing satisfactory standard quality evidently should not result in any advance in the prices quoted to the purchasing department in response to their inquiries. For articles which do not lend themselves to rapid or conclusive laboratory tests and which can be proved satisfactory only by actual usage, a carefully worded and legally sound guarantee clause will have to be inserted in the contract as a safeguard against the delivery of inferior goods.

In general, the specification represents all the initial information required by the purchasing department, but in certain cases it may be supplemented with advantage by a certain amount of general information. In many instances the buyer is in a great measure unacquainted with the composition and origin of the products with which he is dealing and frequently is not conversant with the other trades making use of the same or similar materials. The laboratory, therefore, can often supply information which will enable him to obtain a clearer insight into the factors which may influence the market quotations. The importance of such knowledge must have been realised in many businesses during the past three years of abnormal conditions, and perhaps in the near future the post of buyer may be added to the list of positions for which the chemist possessing business capacity and experience is considered eligible.

The successful examination and control of supplies purchased on a specification basis is almost entirely a question of accurate sampling combined with rapid and reliable methods of testing. The difficulties incidental to securing an average sample, as is well known, will vary greatly from industry to industry. They may be very considerable as, for example, with moist wood pulp, pyrites, and crude rubber, or may be comparatively slight as in the case of the majority of the "fillers" employed by the rubber manufacturer. Where difficulties are likely to be experienced an understanding regarding the methods of sampling and analysis to be employed should exist between the buyer and seller and be embodied in the specification. Before a delivery of material is sampled by the laboratory it should be examined by the store to determine whether the quantity is in accordance with that stated on the invoice. If correct in this respect it should be stored entirely separate from approved factory supplies until the laboratory report is received.

A range of standards should be collected in the laboratory for ready reference, and must be kept up to date as modifications occur in consequence of changed conditions of manufacture or alterations in the sources of supply.

The samples submitted for report by the purchasing department to the laboratory should be accompanied by all the available information likely to be of assistance, especially the price quoted and the names of the suppliers. If the cost is greatly in excess of the standard the sample

in general may be dismissed after a brief examination, and a few preliminary tests together with a comparison with the standard material will serve to eliminate a further proportion of those remaining. At this stage a search should be made through the laboratory reports for the results of the examination of any similar samples previously received from the same source. The information thereby secured will frequently well repay the trouble, since many firms send out samples of their standard products at short intervals to all likely customers. Any laboratory report dealing with this work should be entered on a card index both under the name of the supplier and the nature of the article. Copies of these reports should be issued to the purchasing and stores department, so that they may be discussed at the periodical meetings of the Factory Supplies Committee, and further action agreed on to determine fully the merits of those samples which appear promising as a result of this preliminary examination.

The foregoing duties will evidently involve the laboratory in a large amount of routine work when once the methods of analysis and testing are established on a satisfactory basis. The greater part of this work will therefore call for care and thoroughness rather than originality, and should be within the capacity of the unqualified laboratory assistant. The part of the mill supplies chemist in this connection, therefore, should be limited to securing correct samples and interpreting the results of the analyses, so that he may be able to devote his time to investigations of a more difficult character arising out of the discussions of the Factory Supplies Committee.

Few technical processes exist which can be claimed as perfect and there are generally places, even in the best managed businesses, where modification of either plant or methods seems possible with a view to either the total or partial saving of some expensive supply or its substitution by a relatively cheaper material. Investigations with these objects in view will probably result in failure more frequently than in success. Failures of this kind, however, should be regarded as tokens of the efficiency of the factory and not as proofs of the inutility of the chemist.

All the varied work carried out by the laboratory in connection with the factory supplies will require to be systematically reported, and copies of these reports should be sent to the buyer, the stores superintendent, and the factory manager. The manager, moreover, should be supplied with a résumé of the matters discussed at the Supplies Committee meetings, and any proposal involving alteration in either the quality or the source of any particular supply should be submitted for approval to him and those responsible for the direction of the business before any definite action is taken.

In order to carry out the scheme of control which has been outlined above a manufacturer must offer liberal salaries in order to secure the services of an adequate and efficient staff. This outlay must be considered as a percentage of the total sum spent annually in the purchase of the factory supplies. Calculated in this manner and judged merely as a means of ensuring the correctness of supplies, both in quality and quantity, the expenditure should require little or no additional justification. When, however, allowance is made for the savings which can be effected both by purchasing on a competitive basis and by economies in factory use, together with the reduction in manufacturing troubles and the enhanced sales resulting ultimately from a more uniform product, no reasonable doubt can exist that, as usual, efficiency is the truest form of economy.

London Section.

Meeting held at Burlington House on Monday, June 18th, 1917.

MR. A. R. LING IN THE CHAIR.

THE UTILISATION OF THE SULPHUR CONTENTS OF ZINC ORE.

BY H. M. RIDGE.

Spelter was formerly made only from calamine, which is the carbonate of zinc, but as the world's supply of this mineral is limited it became necessary, particularly about the middle of the last century, to use zinc sulphide ore, and the demand increased very rapidly.

The main source of spelter to-day is zinc blende. When pure this consists of zinc sulphide with 67% zinc and 33% sulphur and is a white transparent mineral. The pure mineral is rarely found; zinc blende is generally black or brown and contains several per cent. of iron as amorphous FeS , and frequently also some manganese. In consequence of impurities, the sulphur content is usually less than the above-mentioned figure, but if pyrites, FeS_2 , is present, the sulphur assay rises.

In the ore deposits zinc blende is usually associated with galena and occasionally with copper pyrites, but it is found with most sulphide ores. No particular kind of gangue predominates; in addition to quartz, calcite, strontianite, magnesite, ankerite, siderite, barytes, and fluorspar are frequently present. Quartz and calcite are lighter than blende, barytes is heavier; the differences in specific gravity are sufficient to allow of separation by ordinary wet methods of concentration. If fluorspar is present wet concentration should be carried out carefully because it is desirable to remove fluorine, as far as possible. Siderite and ankerite have been taken out efficiently on the Continent on magnetic separators after a preliminary flash roast to form magnetic Fe_3O_4 .

The utilisation of the zinc contents of the big deposit of argentiferous zinc and lead ore at Broken Hill presented unusual difficulty, because of the presence of garnet and rhodonite of about the same specific gravity as zinc blende. This was first overcome by the use of the Wetherill electro-magnetic separator with an intensely strong magnetic field. When I started the first of these plants at Broken Hill in 1899, we lifted the garnet and rhodonite out of the ore with one set of machines and then passed the residue through an even stronger field which separated the zinc blende from the galena, quartz, and calcite. The process was too expensive to be able to compete permanently and was superseded by the modern methods of flotation; to-day the whole of the zinc concentrates at Broken Hill are produced by flotation. Unfortunately, flotation methods are not, up till now, effective for separating fluorspar or carbonates from blende.

The rapidly-increasing consumption of spelter threatened to cause a shortage of ore as long as calamine was the main source of supply, but improved methods of concentration and of smelting have resulted in making available enormous resources of sulphide ore and there is an adequate supply of suitable concentrates to cope easily with all prospective demands.

I propose, in dealing with the utilisation of the sulphur contents of zinc ore, to divide the subject into:—

1. The extraction of the sulphur from the mineral.
2. The utilisation of the sulphur.
3. Statistics and economics.

The sulphur can be separated from the zinc by:—

(a) Smelting with a metal having greater affinity for sulphur.

(b) Treatment with the oxide of a strong base.

(c) Heating in the presence of oxygen.

Zinc sulphide is decomposed by molten metallic iron or copper and a sulphide is formed, while metallic zinc vapour is driven off. Considerable experimental work has been done on this process, but without success, because of the expense of roasting the iron or copper sulphide and the possibility when copper is used of losing some of this metal in the process. The operation has to be carried out in a retort or crucible at a high temperature. This has some similarity to the ancient methods of brass manufacture by smelting copper ore and zinc carbonate together with carbon.

Zinc blende can be smelted with lime and carbon to form zinc, carbon monoxide, and calcium sulphide; this has been carried out in an electric furnace but it entails a continuous fresh supply of lime, while the resulting impure sulphide of lime quickly oxidises to sulphate and has to be run to waste.

The usual method of separating the sulphur from blende is to roast the ore with a sufficiency of air to form zinc oxide and sulphur dioxide. This is the method in general use.

The further treatment of the zinc concentrates after roasting consists in heating the zinc oxide in retorts, with suitable reduction material, to reduce the oxide and distil the reduced metallic zinc which is cooled and condensed to liquid metal.

In roasting zinc blende the sulphur is oxidised to SO_2 with a small amount of SO_3 , and sufficient oxygen is required for the formation of zinc oxide. The reaction is exothermic, but it is not possible to obtain a sweet roast without the application of heat. Sulphates are formed in roasting and these have to be decomposed; this necessitates additional heat units.

The heats of formation are:—

$$\begin{aligned} (\text{Zn} + \text{S}) &= 43,000, \\ (\text{Zn} + \text{O}) &= 84,800, \\ (2\text{S} + \text{O}) &= 69,260. \end{aligned}$$

If 97 kilos. of zinc sulphide is oxidised completely with air containing 48 kilos. of oxygen, 81 kilos. of zinc oxide and 64 kilos. of sulphur dioxide, equal to 22.22 cubic metres, are obtained. 208 kilos. of air with 160 kilos. of nitrogen will be used.

The reaction gives:—

$$\begin{aligned} \text{Formation of 81 kg. ZnS} &+ 84,800 \text{ calories.} \\ \text{Formation of 64 kg. SO}_2 &+ 69,260 \text{ "} \end{aligned}$$

$$\begin{array}{rcl} \text{Total} & 154,060 & \text{"} \\ \text{Decomposition of 97 kg. ZnS} & - 43,000 & \text{"} \end{array}$$

$$\text{Net heat evolution} \quad 111,060 \text{ "}$$

In practice this result is not obtainable; the ore and the air have to be heated up, while the roasted ore and the sulphur fumes are discharged at a high temperature and as the heat units cannot all be retained in the furnace, coal has to be burnt to maintain the temperature and to remove the last units of sulphur.

If the sulphur has to be used for technical purposes, the fumes must not be contaminated and diluted with fire gases.

Constructional difficulties were encountered in the design of furnaces for this purpose. Muffled furnaces have to be used in which the fire gases do not come into contact with the ore, and the heat units have to be passed through fire brick in order to maintain the heat while the last units of sulphur are being oxidised and while any sulphates, which may have been formed, are decomposed.

In Germany and Belgium prolonged efforts were made to prevent the emission of large quantities of sulphur fumes into the air and the consequent destruction of vegetation in the neighbourhood of the works, and the first practical results were obtained about 1855 by Hasenclever, who, after a series of experiments, built a furnace at the Rhenania works. This is shown in Figure 1.

FIG. 1.

The furnace has two roasting hearths, of which only the top hearth is muffled, and after the ore has been rabbled along this hearth and has given off some of its sulphur, it is dropped to the bottom hearth to complete the roasting in direct contact with the fire gases. The arches of the furnaces were too high for practical work and the fumes were low in SO_2 .

In 1865 a much improved furnace was built by the Rhenania Co., and this is illustrated in Figure 2. The results improved, but the capacity

FIG. 2.

of the furnace was small and the strength of the gas continued deficient; it is worthy of note that the designer realised that it was only necessary to heat the ore during the last stages of oxidation, because there is enough heat at the commencement of roasting, but this point was overlooked for many years. The general idea of the construction of the furnace is very similar to that of "Delplace," which will be referred to later.

An effort to reduce the amount of labour was made in 1872 with the furnace shown in Figure 3. A number of these furnaces were built at various works in Germany, but they again laboured under the disadvantage of the final roast being carried out in contact with the fire gases. The furnace had 215 square feet of area on the bottom direct fired hearth and above this a muffle of the same size was heated from above and below by the fire gases. The incline had an angle of 13° , which had been determined by experiment, and baffles were placed in this, so as to spread the ore in a fairly uniform thin layer. Openings were arranged for access in case of blockage. The ore travelled a total distance of about 90 feet in the furnace.

Much labour was required for breaking up lumps of ore which formed, and the furnace had to be very carefully tended. During the period when much sulphur is being given off the ore will run like water if the temperature rises too high, and if iron or lead are present in appreciable quantity, the overheated ore will set hard. This frequently

FIG. 3.

occurred on the incline and the design was finally discarded, because more labour was required for freeing the incline than is necessary for working a horizontal hearth. The output of the furnace per 24 hours was about 3 tons of roasted ore with a coal consumption of 15 cwt., and three men were necessary per shift, so that the output per man per shift with a 12-hour shift was only 10 cwt.

In the furnaces which were designed for part of

the work to be done in the muffle and the balance in a reverberatory, only about two-thirds of the sulphur contents were available for further use, while the remaining one-third was so diluted by the fire gases that it had to be allowed to escape into the atmosphere.

In England attempts were also made to roast zinc ore in muffled furnaces, but they were not entirely satisfactory. It is remarkable that the first roasting of blende appears to have been done here. In 1758 John Champion of Bristol obtained a patent for using blende or black jack in the manufacture of brass.

The first of the furnaces of the so-called Rhenania type is shown in Figure 1; this was built in accordance with a German patent of 1882. The furnace is provided with one fire box, and the fire gases travel four times the length of the furnace, which has nine muffles each 2 ft. 5½ in. wide and four hearths in which the ore is rabbled by hand at right angles to the direction of the travel of the fire gases. The air for the muffles is preheated and the sulphur fumes leave the furnace with about 6% SO₂. The capacity is 3 to 3½ tons of roasted ore with a coal consumption of 27%; the ore remains in the furnace about 48 hours. Improvements were made in this furnace by cutting out the division walls between the muffles, so that the ore could be rabbled sideways along the hearths in the opposite direction to the travel of the fire gases; later it was found unnecessary to heat the upper parts of the furnace because the oxidation of the ore gives off sufficient heat, but before this stage was reached furnaces were built embodying almost every conceivable variation in the arrangement of the fire flues and the muffles.

Twelve years ago I still built furnaces with three superimposed muffles, the fire gases travelling beneath and above the bottom muffle, whereas it is only necessary, with proper design, to pass the fire gases under the bottom muffle. I found that in one part of the furnace, the fire gas was no longer heating the ore but that heat units were being transferred from the ore to the gas.

For the sake of completeness I illustrate one of the later modifications of the Rhenania furnaces in Figure 5. This furnace is 47½ feet long by 17½ feet wide, so that the ore travels a distance of 118 feet along the hearths. With a 12-hour shift a total of 8 men were required for the pro-

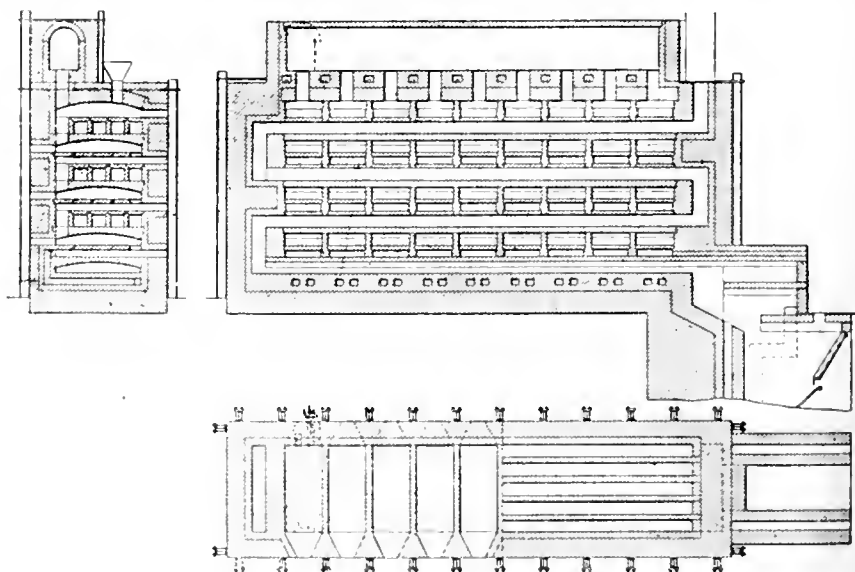

FIG. 4

duction of 6 tons of roasted ore per 24 hours. By working with 8-hour shifts only 6 men were required and the production per man per shift rose from 14 or 15 cwt. to 18 or 19 cwt. The coal consumption is about 25%.

These furnaces have been generally built together in blocks of four and have been more largely used than any other type of furnace.

Owing to high price of fuel, "Delplace" furnaces have, since 1895, been largely built in Belgium; Figures 6 and 7 show the details of this furnace,

have also been erected in this country and in Germany. Experienced labour is required to work them satisfactorily and the men prefer to work on the Rhenania furnaces in which the ore is rabbled sideways, whereas in the Delplace type it has to be alternately pushed from and drawn towards the worker.

Work on zinc ore-roasting furnaces is most laborious, and even on the Continent continuous efforts have, ever since the start of the industry, been made to replace hand labour by machinery.

FIG. 5.

The first attempt to do this was made by the Société de la Vieille Montagne, who succeeded in carrying out the first part of the operation in a furnace like a MacDougall burner for pyrites fines—the furnace is shown on Figure 8. The ore, after passing over three or in some of the furnaces, over four hearths, drops to two hand rabbled hearths similar to those used in the Rhenania furnace. The mechanically stirred part had a diameter of 8 feet, but although various modifications of this furnace were tried it was not much used, mainly because of mechanical difficulties, which 40 years ago proved insuperable. The furnace is stated to have been able to treat $3\frac{1}{2}$ tons of ore in 24 hours with 17% of coal and $\frac{3}{4}$ horse-power.

In America, where hand labour was even more difficult to obtain, it was impossible to use hand

which, with good labour, and if carefully built, gives satisfactory results. The travel of the ore on the 7 superimposed hearths is only 40 feet, but the ore is exposed thoroughly to the air because the arches are low and only a thin bed of ore is maintained on each hearth. Only 16% of coal is required for heating. These furnaces have been built mainly in Belgium and in France, but a few

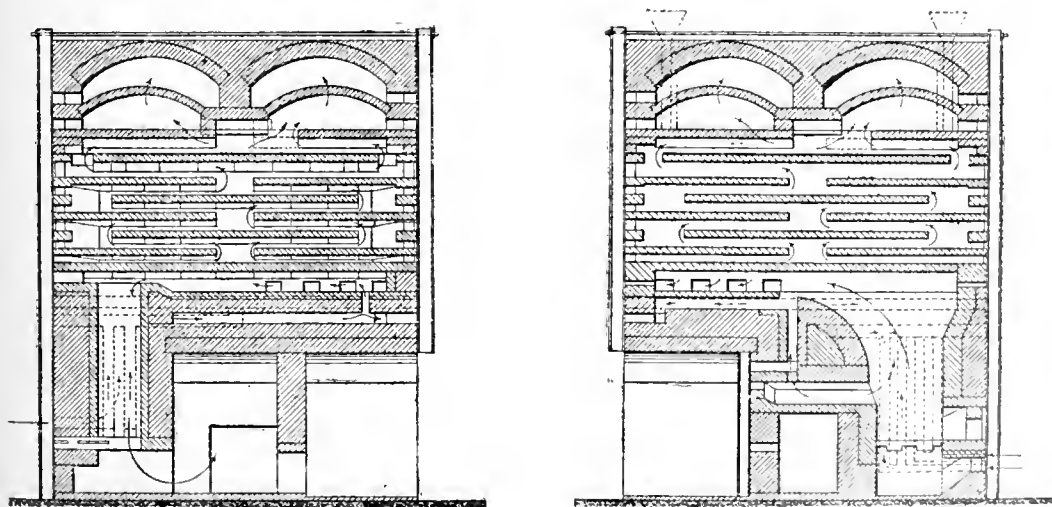

FIG. 6.

down and put out of commission. I understand that on the Continent it has only been possible to work a furnace continuously for a maximum of three months before the arches have to be removed and overhauled, because no repairs can be carried out while the furnace is working.

Figures 15, 16, and 17 illustrate the general

FIG. 9.

design of the Ridge mechanical zinc blende furnace, in which, after experiments extending over many years, the mechanical arrangements have been so far worked out that freedom from mechanical difficulties is assured, while the whole furnace is accessible. The shafts are each made in one piece and are water-cooled; about 15,000 gallons of cooling water is passed through the shafts in 24 hours to prevent overheating. The rabblers which stir the ore are easily and quickly renewed and the part to be replaced weighs only 5 lb. The ore is fed continuously to the drying hearth on top of the furnace and passes over three roasting hearths and finally to the cooling hearth, where it serves to preheat the air required for the oxidation. The mechanism of each furnace is driven by a separate electric motor which takes 8 to 10 horsepower. The motor and all the gearing are on a solid foundation beneath the furnace and fully accessible. The discharge opening is separated from the gearing by a brick wall to keep out all dust. The furnace runs noiselessly, the only sound being the hum of the motor. It is gas-fired and the gas is burnt only under the bottom roasting hearth. Broken Hill zinc concentrates are roasted down to 0.75% total sulphur with a feed of 12 tons of ore per day of 24 hours and a coal consumption of 10%. The sulphur fumes leave the furnace with 6½ to 8½% sulphur dioxide and at a temperature of 380° C. so that they can be used satisfactorily in the lead chamber process. One man per shift can attend to the furnace and the producer.

Zinc concentrates with 14% lead have been satisfactorily treated and also concentrates with 17% iron; when roasting an ore, high in lead or iron, it is essential that a mechanical furnace be kept working continuously, because half an hour's stoppage means that the ore on the hearths sets hard and forms lumps which have to be broken up. It has been found possible in this furnace to use the rabblers for breaking up the lumps, and the gearing can, if necessary, be run alternately backwards and forwards till the hearths are free.

I have dealt at length with the design of furnaces for roasting the ore, because this question has played such an important part in the past history of the art, and the utilisation of the sulphur contents of the ore, and, in fact, the treatment of zinc blende has only become possible in consequence of the development of furnace design.

In some ores the presence of substances which interfere with the desulphurising is important; lime, magnesia, strontia, and baryta, if combined with sulphur, retain it in the roasting furnace; if combined with carbonic acid, this is driven off and in some cases the lime, etc., will take up sulphur from the ore. In considering the sulphur contents of roasted blende, allowance must be made for this combined sulphur. Lead becomes a nuisance in hand-rabbled furnaces, but in a properly designed mechanical furnace I have found no trouble; if ore high in lead is treated continually an accretion will form on the hearths, but the rabblers can be made to remove this. High iron content is found in some Spanish and German ores and makes complete roasting in hand furnaces almost impossible; in Germany, I was able, in a mechanical furnace, to reduce the sulphur left in

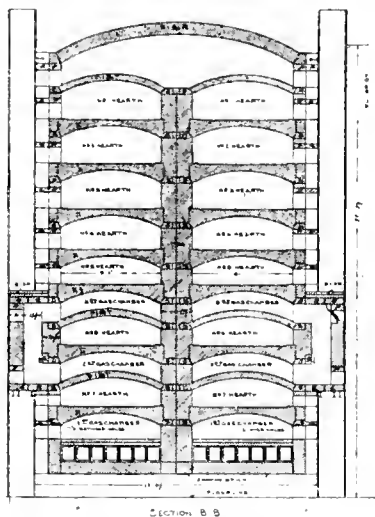

FIG. 10.

the roasted ore to more than 1% less than had been possible in hand furnaces.

The sulphur dioxide given off in roasting is utilised for making sulphites, liquid SO_2 , or sulphuric acid.

Aluminium sulphate has been made at Flone in Belgium by passing the roaster gases into large chambers excavated in the hill side and filled with alum shale. At Anspin this method was also used for making alum with gas from reverberatory furnaces; it seems that sulphite is formed and this readily oxidises to sulphate.

The manufacture of liquid SO_2 was started by Grillo at Hamborn in Westphalia, because the fumes from the roasting furnaces were low in SO_2 .

FIG. 11.

and it was, at that time, considered impossible to utilise them for making sulphuric acid. The furnace gases pass to a scrubbing tower sprayed with water, which dissolves the sulphur dioxide, and the liquor gravitates to a series of pans, which are placed over the burners, the heat of which is sufficient to drive off the SO_2 gas, which, after being cooled, is compressed and liquefied at a pressure of 7 atmos. In Germany two plants are in operation, viz., one at Hamborn and another at Lipine in Silesia, but, in this country, the method has not been employed on the fumes from zinc ore. The demand for liquid SO_2 is limited.

The main commercial use for the sulphur fumes is the manufacture of sulphuric acid and this can be carried out in lead chambers, or by the contact process.

ores, to circulate the tower acids, the fluorine contents seem to remain in the circuit so that the attack on the packing of the towers gradually increases, but, contrary to expectation, I have not found increased corrosion of the lead work of the chambers by fluorine. Many efforts have been made to overcome the trouble with the packing. Glover towers have been built entirely of lead, and with lead sheets as a packing, so as to avoid the use of silicious material, but it is found necessary in this case to use two Glover towers in series, the first one being an empty tower followed by a tower filled with suspended lead sheets. I have found it preferable to overcome the trouble by passing the whole of the chamber acid through the towers instead of only circulating the tower acids, and by this means

FIG. 12.

Most zinc ores offer the advantage of being free from arsenic, but on the other hand they frequently contain fluorine of which even as little as 0.01 to 0.02% becomes noticeable. Fluorine occurs with the ore as calcium fluoride, which is decomposed in the roasting furnace in the presence of silica and forms silicon fluoride. If this gas passes into the Glover tower it is decomposed and hydrofluosilicic acid is formed; this, in turn, appears to split up. As it is usual, when treating zinc

keeping down the fluorine contents of the acid, and at the same time to pack the towers with a well-burnt brick packing of a suitable composition which would offer the maximum possible resistance to the attack of hydrofluoric acid. Glover towers built in this way, and properly operated, have been worked continuously for 12 months and longer without trouble.

Other important impurities affecting sulphuric acid manufacture are antimony, mercury, and chlorine.

Some years ago I experienced trouble in consequence of the unexpected presence of chlorine, and on investigation I found that this was due to the ore having been left lying for several months on the Wharf at Port Pirie, and sprayed with seawater in order to avoid loss by windage.

Mercury is found in some Spanish blendes. It collects at the outer parts of the dish of the lead chamber, where it is not protected by lead sulphate and causes rapid corrosion of the lead. This can be overcome by lining the sides of the dish with thin brickwork.

Antimony occurs frequently in small quantities with zinc blende, and at the high temperature of the roasting furnace some of this is volatilised and passes into the acid. On one occasion I received serious complaints about the presence of arsenic, but found, on examination, that antimony was the cause of the trouble. Antimony was found in the zinc concentrates from Broken Hill when treating ore from the upper levels in one of the mines, but the quantity present was less than 0.03%.

Most zinc ores have lead associated with them, and some of this is generally driven off with the sulphur in the roasting furnace together with the silver which is combined with the lead, but both

the lead and the silver are deposited in the chamber sludge.

The lead chamber process, when working with hand furnaces, has to be carefully watched because of the intermittent evolution of sulphur dioxide in consequence of intermittent rabbling of the ore. In Germany it has been usual to reduce this difficulty by arranging for the furnace hands, working on the different furnaces, to start their shifts at different times, but, in spite of this, it is not possible to obtain a continuous current of uniform gas throughout the 24 hours, and, unless the process is watched carefully, loss of nitre is the result. With modern mechanical furnaces this trouble does not occur.

The design of the chamber plant does not call for special comment. It is in every way similar to that used when burning pyrites.

The nitre consumption, and working cost of the plant, are not higher than with pyrites.

Here and in Belgium lead chamber plants have been used exclusively for making acid, and in Germany this is also the rule, but there are several

The average price realised in 1915 was \$8.85 per short ton.

The use of the contact process for fumes from zinc ore made the biggest strides in the United States, because there the smelters are largely able to rely for their ore supplies upon the produce of one or more mines, and are not dependent upon small parcels of ore shipped from various parts of the world, as has been the case here and on the Continent. They have consequently been able to make provision for eliminating any harmful ingredients which may be present in the raw material which they expected to be treating over a long period. The American smelters also have the advantage of having practically no hand-rabbed furnaces.

The various contact poisons can be eliminated if the tonnage to be treated warrants the initial expenditure on the plant. Fluorine, arsenic, antimony, and lead can be removed by first scrubbing the gas with a suitable liquid, and when this is done the conversion offers no greater difficulties than when brimstone or pyrites is burnt.

Merton Duplex Furnace with Drying Hearths, erected at the Irtlysh Corporation Works, Ekibastous, Russia.

FIG. 13.

contact acid plants at work as well. In America 14 zinc smelters make sulphuric acid, but they mainly use the contact process.

Calculated as 60° B. acid, the American production from zinc blende was—

In the year 1911—	230,643 short tons.
1912—	292,917 short tons.
1913—	296,218 short tons.
1914—	111,911 short tons.
1915—	484,912 short tons.

In England acid has only been made from zinc ore in three plants, and I estimate that their output does not exceed 25,000 tons a year of 140° Tw. acid. This tonnage corresponds to a production of about 10,000 tons of spelter. In 1913 31,290 tons of virgin spelter was made in the country. Part of this was made from calamine, but the available supplies of this ore are steadily decreasing, and it is only a question of a short time, when the whole of the metal will have

to be smelted from zinc blende. The position is really worse than is indicated by these figures, because it has been customary to roast the sulphide ore in reverberatory furnaces from which the fumes cannot be used, so that the sulphur is wasted and the atmosphere polluted.

To illustrate the importance of the utilisation of the sulphur of zinc ores I will refer to the figures for Upper Silesia. The district produces about 60% of the spelter made in Germany, but a good deal of calamine is still available there, so that the maximum production of sulphuric acid from blende has not been reached; the tonnage of calamine treated steadily decreases, but the increased amount of blende compensates for this, and allows of an

Vertical Section through the Spiral Roasting Furnace.

View of one of the Hearths of the Spiral Furnace.

FIG. 14.

increasing spelter and acid production. The last figures available are for 1911, and the accompanying table shows the results for every fourth year since 1887.

Statistics from Upper Silesia.

Year.	Raw blende roasted.	Sulphuric acid refined to 50° B.	Sale value.	
	Metric tons.	Metric tons.	Total marks.	Metric ton of 50° B. acid.
1887	53,882	21,013	479,000	22.81 marks.
1891	66,236	32,676	746,000	22.85 "
1895	84,857	33,229	778,000	23.43 "
1899	123,602	64,029	1,074,000	16.77 "
1903	187,596	104,268	1,728,000	16.62 "
1917	421,006	139,840	2,187,000	15.65 "

1912	—	274,908	—	—

Six works still used their old reverberatory furnaces, so that not all the sulphur could be utilised, but for some years factory legislation has prohibited the emission of noxious fumes and as the plants become worn out they have

The position in the zinc smelting districts in Western Germany is analogous, but the make of acid there is larger in proportion to the production of spelter, because there is no local supply of calamine. The newer smelting works have been placed on navigable waterways so that freights on raw materials and finished products are low. The chamber process is used in all the works except one which has a contact plant; there is also one installation making liquid SO_2 .

In 1913 in Germany 554,760 metric tons of blende was roasted for making sulphuric acid; of this 87,639 tons was imported from Australia and 56,181 tons from other countries.

In Belgium blende is mainly roasted by the chemical manufacturers, who retain the sulphur and receive from the zinc smelter in addition a payment of 6 to 8 francs per 1000 kilos. for roasting the ore. This was facilitated by the low freights on the canals, which reduced transit charges to a very low figure. In Belgium 65% of the total production of sulphuric acid is made from blende; the amount of zinc acid is nearly 400,000 tons.

The most important and serious factor for consideration here in England is the shortage of zinc smelting capacity in the country. In 1913

Figs. 15, 16, and 17.

to be replaced by modern installations. The fumes from the reverberatory furnaces are scrubbed with milk of lime which is sent to waste. Five plants have lead chambers and make acid of 50°—55° B.; this is generally concentrated in cascades or Kessler apparatus and in recent years largely in Gaillard towers. Three works have contact plants as well as lead chambers. There was in 1912 a total of 48 lead chambers.

Of the total production of acid, 11,055 metric tons was sold as acid of 50° B., 111,316 metric tons was sold as acid of 50°—60° B., 42,319 metric tons was sold as acid with 98—100% H_2SO_4 , 216 metric tons was sold as oleum with 20% SO_3 , 1771 metric tons was sold as SO_3 , and in addition 28.55 metric tons of liquid SO_2 was made.

The acid is used for making superphosphates, sulphate of ammonia, dynamite, and gun cotton, and for refining mineral oil. It is distributed by rail over a wide area, some going into Russian Poland, Austria, Hungary, and even to Roumania.

our consumption of spelter amounted to no less than 224,000 tons of which 74% was imported. After allowing for the metal made by the refiners, we imported about 166,000 tons of spelter and zinc in other forms. If this quantity were all made from blende, the roasting fumes could be used to produce annually 400,000 tons of 110° Tw. acid. There is no reason why this should not be done and the corresponding quantity of brimstone and non-cupreous pyrites displaced as well as a portion of the pyrites which is low in copper.

Before the war the cost of making 140° Tw. acid from zinc ore fumes in this country was only between 8s. and 9s. per ton so that the operation is remunerative and profitable.

Zinc ore must be treated because spelter is required, and if the work is not done here, it will be done elsewhere. Cheap sulphuric acid has always been an important factor in the chemical industries and unless we use the resources of the Empire, others will do it for us and we

shall be obliged to continue to look on while the foreign subsidiary industries using the acid abroad go ahead.

MR. J. H. ROSEASON IN THE CHAIR.

COTTON SEED PRODUCTS.

BY KAPILRAM H. VAKIL, B.A., B.SC.TECH.

The first mention of cotton seed oil was made in 1783, when it was pointed out to the Society of Arts that oil might be extracted from cotton seeds. To encourage the manufacture of this oil the Society offered a prize, but as no application was made for it, although the offer was repeated for six years, no award was made. The seed oil was not expressed successfully till 1847 and no satisfactory progress was made till after the Franco-German war. Since then the growth of this industry has been phenomenal, especially in America. The industry, as will be shown later, has attained enormous proportions in this country and occupies to-day one of the foremost positions among staple British industries.

The following tables will indicate the position of the industry in the United Kingdom.

It will be seen that the bulk of seeds crushed in this country comes from Egypt and India. For nearly fifty years after the establishment of this industry Indian seeds were not known to the crushers, and, as will be shown in Table III., the English demand dates from 1900. Since then the business in Indian seeds has assumed very large proportions, and if the attempts of the Government and the cotton growers prove successful in the near future, India will be the chief country in the world to supply not only cotton but cotton seeds to the British Empire. Considering then the importance both present and prospective of the Indian seeds, I propose to treat in detail certain aspects of the cotton seeds of India. The total area under cotton in India has been of late nearly 23,000,000 acres, and the total estimated output of cotton from this acreage is 4,500,000 bales of 100 lb. each, or about 800,000 tons of cotton. From these figures the quantity of seeds produced during the year may be roughly calculated on the basis of 30% lint and 70% seeds, which amounts to nearly 1,870,000 tons. The amount of seeds required for agricultural purposes would be, at the rate of 11 lb. per acre, about 190,000 tons, leaving 1,680,000 tons for feeding cattle and for crushing. In 1901, when Indian seeds were first introduced into England, there was then produced in India 1,260,000 tons of seeds. This huge quantity of seeds was practically wasted, and, as will be seen from the following figures, the value of these seeds in the Indian market was very low. From the following table it will also appear that although large quantities are shipped to England the export is very small compared with the total production. In 1912 a movement was on foot in this country to send a commission to India to enquire why so small a pro-

portion of the total output of seeds appeared in the markets of Great Britain.

TABLE III.
Indian exports of cotton seed.

Year.	Tons.	Total value. £	Value per ton in India. £
1897-98	1,118	5,087	3.6
1900-01	11,240	36,939	3.3
1905-06	199,567	681,160	3.6
1910-11	299,011	1,539,173	5.1
1911-12	203,605	1,012,752	5.0
1912-13	130,568	685,127	5.2
1913-14	284,326	1,416,743	5.0
1914-15	207,788	1,001,524	5.0

Practically the whole of this export trade is with the United Kingdom, mainly from the port of Bombay; *e.g.*, of the 284,326 tons shipped from India in 1913-14 the share of Bombay was 260,121 tons. In short, the whole trade may be said to be between Bombay and Hull.

From Table I, it will be seen that there are principally two varieties of seeds crushed in the United Kingdom, the Egyptian and Indian. The composition and characteristics of these seeds vary considerably. I do not propose to classify the seeds botanically—since the controversy regarding the number of species of cotton seeds is still undecided. For all practical purposes, and particularly from the oil-crushers' standpoint, Buchanan-Hamilton's classification of all cotton seeds into black or naked seed and the white or fuzzy seed will be quite sufficient. The Egyptian seed belongs to the former class. The treatment of this seed for the expression of oil differs considerably from that of the Indian, which belongs to the second division. The Indian seed has on it a double layer of fibre, the under layer or fluff or lint as it is called by the seed-crusher, and the outer layer of the cotton fibre proper. The seeds as they come into the market contain considerable quantities of foreign matter, *e.g.*, dust, sand, dried leaves, stalks, cotton-balls, etc. In addition, they contain broken, diseased, and lighter seeds, which are useless to the miller. Bulletin No. 53 of 1912 of the Indian Department of Agriculture gives the following percentages of sound seeds obtainable from the bazaar seeds:—

TABLE IV.

	Light seeds.	Foreign matter.	Sound seeds.
	%	%	%
Poona Bazaar	13.5	14.0	72.5
Khandesh	21.8	6.7	71.5
Nadiad	15.6	6.4	78.0
Iroach	16.9	7.2	75.9
Dharwar	13.5	4.8	81.9
Average	16.2	7.8	76.0

These percentages for sound seeds seem to be too low. From hundreds of samples examined in my laboratory during the last five seasons I find that on an average there are 92% of sound seeds and 8% of damaged, including foreign matter. The presence of damaged seeds is highly objectionable in seeds that have to be sent abroad or stored during the monsoon. Damaged seeds result mainly from the carelessness of the ginner or from his attempts to increase the output of the gins. This is very much to be regretted, for to my mind the bad reputation of Indian seeds in the foreign markets is due mainly to the ginner's total disregard of what happens to the seeds by

his rough handling of them. It may be mentioned in passing that the type of gin used determines also to a certain degree the percentage of damaged seeds. Saw gins are not much used in India, and their use is limited to the Dharyar district. Roller gins are generally used all over the country, and the best results, so far as sound seeds are concerned, are obtained by Platt's gins. Dobson's coming next to them. It is not possible to go into details in this paper with regard to the composition of Indian seeds, for from my experience I find that no two samples of seeds are alike. Seeds from the same district, from the same ginning factory, even from the same field, have differed so widely that to attempt to draw any general conclusion from the analysis of a few samples would be entirely incorrect and misleading. A very large number of analyses are recorded by Mollison in the Agricultural Ledger, No. 9, 1903, published by the Department of Agriculture of the Central Provinces, and in Noel-Paton's "Indian Cotton Seed," published by the Government of India. The figures given there are fairly accurate and may be safely taken as representing the average composition of Indian seeds. The following typical analyses which I have made give a general idea of the average composition of Indian seeds.

TABLE V.

	Oil.	Med. ex oil.	Husks and lint.	Sound seeds.
	%	%	%	%
Amalner	29.17	35.33	41.50	87.40

Pandher Kavda	18.36	26.19	55.45	95.85
Average	19.67	34.68	45.65	91.77

Indian seed is valued in this country on the basis of 18% of oil. As the trade conditions prevail at present this figure may be taken as fairly correct, but a large amount of work in this direction has convinced me that the percentage of oil in the Indian seed is capable of being raised by co-operation between the Departments of Agriculture, the farmer, and the ginner. As it is, the seeds from the central Provinces have shown an oil content as high as 23% and on an average 19.5%, and as such they compare favourably with good American seeds. Seeds from the Central Provinces are quoted a little higher in the bazaars and are highly valued by the seed-crushers. The hulls with the lint and moisture form about 43 to 55% of the seeds and on an average 48%. The lint from Indian seeds, removable by American de-linting processes, forms about 1.5% of the seed. This includes lint obtained by reginning the cotton balls which are found in the seeds sold in the bazaar.

On a manufacturing scale the following products are obtainable:—Lint, 1%; decorticated cake, 40%; hulls, 14%; oil (crude), 13%; wastage, 2%. In the report of one of the oil mills now operating successfully in India the following figures of its working on a large scale were given:—Refined oil, 12%; decorticated cake, 42%; hulls, 38%; lint, 1%; soap stock (foots), 2.5%; wastage, 4.5%. This means that the process followed by them is not the "pure" process—which will be discussed later.

American "Uplands" seeds resemble the Indian seed in many respects. The Indian seed, however, has more lint or short fibre remaining on it after ginning. This condition of the seed requires very

careful handling in the extraction process as the fuzzy mass which forms the covering of the seeds absorbs oil very readily from the meal during the preliminary processes of hulling or crushing, this oil being lost to the miller. The Indian seeds are much smaller than the Egyptian and American.

	Length in mm.	Diameter in mm.
Indian	7.0	4.0
Egyptian	8.5	4.5
American	11.0	6.0

This difference in size is specially to be noted as its consideration is important in decorticating by the American process.

When the Indian seeds were first investigated there was a good deal of doubt expressed as to the adaptability of American decorticators for Indian seeds. Experience has shown that if in the American decorticators the clearance between the "breast knives" or concave knives and the cylinder knives be well adjusted to suit the requirement of the Indian seeds, the percentage of whole seeds dropping out undecorticated is almost nil. The small size of the seed no doubt makes it very difficult to handle during this process, but a little skill and the use of a secondary disc-huller removes all the difficulties and the working is made quite satisfactory. There is still much to be desired in the designing of decorticators for small seeds by way of easier or automatic adjustment of knives, their sizes, concavity, speed of the cylinder knives, etc. The husk of the Indian seed is also different from the American, which is less tough and easily manageable in the decorticating process.

There is a very marked difference between the hulls of Indian and Egyptian seeds. The former contains a brown colouring matter easily extracted with water, and on this property and the behaviour of this colouring matter with sodium hydroxide and nitric acid a means of detecting the presence of Indian seed hulls in Egyptian cakes has been suggested (Oil and Colour Trades Journal, 1905, p. 1815). The chief points of difference in the crude oils obtained from these different seeds are: (1) There is a higher percentage of free fatty acid, colouring and albuminous matters in the Indian oil than in the Egyptian or American oils, which gives rise to a greater loss in refining, sometimes exceeding from 16 to 20%. (2) The oil from Indian seeds is poorer than American and Egyptian oils in the solid "stearin" obtainable from it, and not quite so well suited for margarine making. Egyptian and Indian oils are inferior in colour to American oils. (3) The oil from Indian seeds retains a peculiar fishy odour which it is very difficult to get rid of even with drastic treatment. (4) The greatest drawback to the oil from Indian seeds as an edible oil is that the refined oil shows a bluish-green fluorescence. This fluorescence is not removed by the ordinary process of refining. If the traces of fishy odour and the fluorescence could be removed easily and at small cost the oil would find a ready market in India as an edible oil. At present, though sold in large quantities as edible oil, it does not command as high a price and is not valued so much as the best grades of cold pressed TII oil. (5) The refined oil from the Indian seeds has a higher iodine value—112 to 116—than the oil from Egyptian seeds, which varies from 106 to 108, or the American, which varies from 105 to 110. This higher iodine value may be due to the fluorescent substance in the oil.

Before concluding this part of the paper on the special features of Indian cotton seeds, I will refer briefly to the position and prospects of the cotton seed oil industry of India. With the opening of the English demand for Indian cotton seeds a suggestion was made in 1903 at the Upper India

Chamber of Commerce to utilise the seed that was practically wasted. This suggestion was followed by the setting up of a small oil mill by the Government for experimental purposes in Cawnpore. The interest of Indian manufacturers was stimulated by the wide publication of the Government of India's bulletin and by the success of the oil mill set up in Burnah by Messrs. Jamal Bros. It was then that the late Mr. Tata, to whose foresighted enterprise India owes her great cotton and iron and steel industries, decided to enquire into the possibilities of this industry in India. The large experimental plant set up near Bombay handled thousands of tons of seeds from all parts of India, and the results obtained by this mill proved beyond doubt the immense potentiality of this industry in India and of the high grade of products that could be obtained when the seeds are pressed fresh on the spot. The result of this experimental working of the Tata oil mill for four seasons was made the basis of a new undertaking at the end of 1913, starting with a capital of £200,000. This scheme unfortunately was not carried through on account of the great banking crisis in India which was followed by the war. The scheme, however, will be taken in hand as time and circumstances permit. As the Tata oil mill was only meant for experimental purposes it had to be closed down on the completion of the experiment, but about a year after the commencement of the working of this mill another mill was set up in 1912 on a proper commercial basis, and though it had the advantage of the market created by the former mill it had to do a great deal of spade work, which, however, resulted in success. This mill, the Indian Cotton Oil Mill, of Naosari, near Bombay, recently added a considerable amount to its capital for extension. Its cotton seed cakes are now quite well known in the London market.

It was my intention at first to confine the subject matter of this paper to my experience of the Indian seeds, but as it was found that the literature on this very important subject was very scattered and as there was no detailed and connected communication to this Society on the different products of cotton seeds, I have extended the scope of this paper.

The storage of black or naked seeds, like the Egyptian or long staple Sea Island, does not present Egyptian difficulties, but in the case of the fluffy or woolly varieties—the Indian, the American "Upland," woolly Brazilian, etc.—the question of the storage of seeds is of the greatest importance. The presence of fluff on the seed causes the heating of the seed so well known to the millers. The susceptibility of the fluffy varieties to heating is due to fermentation or bacterial action, in presence of the moisture in the fluff and hull. This action is accelerated by the presence of broken and damaged seeds. The action at first is slow, but with the rise in temperature a very rapid heating results. E. H. R. Barrow (J. Ind. Eng. Chem., 1915, 7, 709—712; this J., 1915, 913) has noted that seeds containing over 10% of moisture are unsafe for storage. J. B. Rather (J. Ind. Eng. Chem., 1916, 8, 604; this J., 1916, 898) has shown that even a short period of heating causes hydrolysis of 10% of the fat. A long period of heating will result in hydrolysis of 70% of fat and 33% of protein, increasing the acidity to seven times the original. Increase in acidity is due to heating and to ageing of the seeds. During the four months of the monsoon in India the high temperature of the air (over 85° F.) and the moisture due to heavy rains set up a very rapid fermentation of seeds, especially in "go-downs" which are not kept dry by a high plinth and well ventilated. Similar conditions prevail during the transit of seeds in the holds of ships, and seeds which were quite healthy and free from mould when shipped from Bombay have been frequently

received in this country in a highly damaged condition. This heating of seeds must be prevented with scrupulous care, since the products obtained depend to a very large extent on the condition of the seeds. The quality of the crude oil suffers on account of the fermentation, giving rise to a larger loss in refining. The colour of the refined oil is poor. Other products are also inferior in quality. A number of processes have been suggested to prevent this fermentation and keep the seeds clean. Wilson (Eng. Pat. 1057 of 1887; this J., 1888, 126) suggests treating the seeds by air heated to 200—300° F. Noel-Paton ("Indian Cotton Seeds") proposes to remove the fluff by singeing. There are a number of processes in which by chemical means the fluff is entirely carbonised and removed. According to Stead's Eng. Pat. 13,831 of 1884 (this J., 1885, 585) the seeds are treated with 4% of sulphuric acid and neutralised with lime. J. J. Green (Eng. Pat. 12,539 of 1902; this J., 1902, 1336) also proposes to carbonise the fluff with sulphuric acid. Other acids besides sulphuric acid are also used. Stead (this J., 1891, 820) suggests hydrochloric acid. Silcock (Eng. Pat. 24,516 of 1893; this J., 1894, 945) uses sulphuric acid but neutralises with mineral phosphates and passes the seeds through cylinders revolving at high speed and lined with emery powder blocks to rub off lint acted upon by acid. Dudley (U.S. Pat. 344,951; this J., 1892, 619) proposes to subject the seeds to fumes of N_2O_4 and SO_2 either in the order named or in mixture, sufficient air accompanying them to regenerate nitric oxide; the fibres powder rapidly and fall off. Zinc chloride has also been used to free the hulls from lint by Kitsee (U.S. Pat. 858,075; this J., 1907, 868); MacFarlane and Reinohl (Eng. Pat. 6634 of 1902 and U.S. Pat. 695,474—695,476; this J., 1902, 918 and 1081) suggest fermenting the fluffy matter with alkali and saccharine substances like molasses. These chemical processes are drastic in their treatment and destroy the valuable lint, and for this reason they have found no wide application. Besides, the destruction of the fluff is objectionable on the ground that in the separation of meats from hulls the felting action of the lint helps in a thorough separation of meats from hulls. This is not possible in the Egyptian or naked variety and in seeds treated chemically. In these cases there is always lost a certain percentage of meats with the hulls. E. H. R. Barrow (this J., 1915, 913) proposes to mix the seeds with 5% of sodium chloride, 2% of starch, and 2% of magnesium carbonate; these substances remove the excess of moisture which causes fermentation. The salt, which is partly absorbed by the hulls, kernel, and lint, acts as an antiseptic and prevents the fermentation of mould on the seeds and so prevents their heating. The most effective treatment would be to delint the seed immediately after ginning, remove all light and broken seeds, and thoroughly clean them and sterilise them by hot-air blasts in a vertical cylinder or spiral conveyors on the counter-current principle. Seeds thus treated and stored in a dry go-down or in silos, keep well for a very long time and yield excellent products. Here I must emphasise the need of stringent measures to stop the dishonest practice of intentionally mixing foreign matter like fine sand, dust, etc., in the seeds that come to the Indian bazaars mainly for export. It seems that importers in this country have allowed this sort of evil practice to continue by permitting a certain percentage of foreign matter, known as "refraction" in trade, in the contracts they make with Indian sellers. Seeds coming to Bombay are systematically mixed in the go-downs with foreign matter up to the limit required by the contracts. The poor reputation of Indian seeds is traceable to this dishonest practice permitted by the trade to con-

tinue. If the quality of seeds is to be improved and better results obtained this practice must be stopped at once. I do not see why it was ever encouraged, as the high freights from India payable on a low oil-bearing seed should have required the imposition of more stringent conditions by the English buyers as to the purity of seeds from Indian sellers.

The seeds are subjected to two different methods for the extraction of oil. The English practice is to crush the entire seed with the lint and husk. The American practice is to remove the lint, decorticate the seed, and then crush the kernels separately. This process is modified by the admixture of a certain percentage of ground hulls with the kernels. These processes are called the undecorticated, the pure decorticated, and the mixed decorticated. The yields of products obtained by these three processes are very different, as will be seen from the following table:—

TABLE VI.

Percentage yields of products by different processes.

	Undecorticated.	Pure.	Mixed.
	%	%	%
Refined oil	12.0	11.0	12.0
Cake	84.0	49.0	46.0
Hulls	nil	44.0	37.0
Lint	0.5	1.6	1.6
Feet	2.0	1.4	1.7
Waste	1.5	2.0	1.7

There should be no lint by the undecorticated process; the small amount shown above is from the regaining of cotton balls obtained in screening. Tattersail and Pearson (Eng. Pat. 17,808 of 1893; this J., 1891, 893) and Stanley (Eng. Pat. 22,954 of 1900; this J., 1901, 710) make use of carding machines to comb or card the lint from the hulls. These carding machines are formed of a concave tapered dish, perforated from outside so as to leave projecting burr edges in the interior, whilst they are acted upon by a tapered cone roller with card teeth and revolving at high speed. The seed is first crushed between high rolls, the meal separated on shaking sieves, and the hulls with the adhering meal passed to carders. This process, though it gives bright products, is the most irrational and uneconomical process I have seen. The first crushing of seeds with lint between high rolls causes a very large absorption of oil by the hulls and lint from the kernels. The cakes and oil obtained by this process are similar to those obtained by the best American decortivating process. The hulls in particular are in a very finely-ground condition, suitable for feeding cattle, and have no sharp edges as found in American type decorticators. I cannot go into the merits and demerits of the different processes in this paper. Each process has its staunch advocates. My own experience has been that the mixed process is in every way most satisfactory.

The very small oil content of the cotton seed has made it necessary to devise means to obtain a maximum yield of oil from the seeds. Numerous methods have been suggested by the combined ingenuity of the chemist and the engineer. Of these the best is that of Johnson (U.S. Pat. 691,312 of 1902; this J., 1902, 263), which is the mixed decorticated process and consists in the addition of a certain proportion, generally about 10%, of ground hulls to the meal before or at the end of the cooking process. The presence of the ground hulls, without in any way deteriorating the quality of the oil, increases the consistency of the cake and makes it more porous, which facilitates the exudation of oil during extraction. A larger yield of oil is thus obtained. Johnson's claim of

an increased yield of from 1—1½% is fully justified by results and by the general adoption of the process all over America. This process, combined with Van Winkle's process (U.S. Pat. 690,331 of 1901; this J., 1902, 263), in which the mass of meal is tempered by heat or live steam before being passed through crushing rolls, yields the most economical results. These two processes mark a very important stage of development in the cotton seed crushing industry. Borax (Oil and Colour Trades J., 1908, 39) has been used to cause the oil to flow more freely and produce a greater yield of oil. The seed is sprinkled with a solution of 30 lb. of borax in 100 gallons of water, using 1½ gallons of the solution to a ton of seed. Borax also acts as an antiseptic, preventing bacterial and mouldy growth, and thus keeps the resulting cake in a bright condition.

Economical production of the oil depends as much on the increased yield of oil as on the refining of the crude oil. A very interesting and suggestive contribution in this connection is that of J. Longmore (this J., 1886, 200). The principal object in refining is to remove the large proportion of colouring and albuminous matter together with the free fatty acids associated therewith.

The properties of the colouring matter have been studied by Longmore (*loc. cit.*) and in greater detail by Marchlewski, Wilson, and Stewart (Eng. Pat. 9477 of 1896; this J., 1897, 530) and Marchlewski (this J., 1897, 906). This colouring matter has been called gossypol; it has the empirical formula, $C_{15}H_{14}O_4$. It is insoluble in water but readily soluble in alcohol, benzene, and other organic solvents and dilute salt solutions. It is insoluble in dilute acids and strong brine solutions but very readily soluble in boiling acetic acid and aqueous alkalis. A very large number of methods, based on the solubility of the colouring matter in aqueous alkali, have been suggested for the isolation or removal of the colouring matter, but it seems that none of them has received as universal an approval as the caustic soda method. Tall and Thomson (Eng. Pat. 15,647 of 1887; this J., 1888, 756) suggested the use of normal sodium carbonate instead of caustic soda, as it has little saponifying action on oil during the refining process. Hunt (Eng. Pat. 17,870 of 1889; this J., 1890, 1045) and Aspinall (Eng. Pat. 11,324 of 1894; this J., 1895, 665) use sodium chloride with caustic soda to salt out the soap formed during refining. Though the graining out is better, the presence of sodium chloride interferes with the removal of the colouring matter. The resulting oil is found to be poorer in quality and deeper in colour. J. C. Chisholm (U.S. Pat. 1,007,612 of 1911; this J., 1911, 1396) makes use of alkali silicate instead of caustic soda. He also uses "metal substituted" bases with an alkali solution (U.S. Pat. 1,010,017 of 1911; this J., 1912, 33). These patents are further modified by him by U.S. Pats. 1,056,261—1,056,264 of 1913 (this J., 1913, 434). In these he proposes to use with alkali silicate substances which produce alkali soap, such as hydroxides, carbonates, and other alkali compounds. Holbrook (U.S. Pats. 1,169,154 and 1,169,155; this J., 1916, 317) first neutralises with caustic alkali and then fixes the colouring matter with silicate. I have tried Chisholm's process repeatedly but without obtaining satisfactory results. The foots no doubt settle down very rapidly and retain very little refined oil in them, but the refined oil is poor and similar to the oil obtained by the process in which sodium chloride is used with caustic soda. C. Baskerville (U.S. Pats. 1,105,743, 1,105,741, and 1,114,095; this J., 1914, 930 and 1162) uses inorganic absorbent material like fuller's earth in presence of an electrolyte, or fibrous vegetable or cellulose matter impregnated with a slight excess of alkali to neutralise the free fatty acids (see also Baskerville, U.S. Pat. 1,130,698; this J., 1915, 434,

and this J., 1916, 477). The cellulose converts the colloidal mass containing precipitated colour and albuminoid matter into a mass which is easily separated from refined oil by filtration. A reference should be made here to the elaborate and detailed tables drawn up by the chemists of the Interstate Cotton Seed Oil Refiners, for official tests of refining cotton seed oil. The tables will prove extremely useful to the refiner (this J., 1913, 797, and 1914, 1069). The loss in refining, and the character and quality of the foots and of the refined oil also depend to a large extent on the mechanical appliances of the refining tank. The great difference between the specific gravities of the oil and the alkali solutions makes it necessary to maintain a thorough mixing of the oil and the alkali. To prevent the heavy alkali solution from settling down rapidly during the refining process, Hunt (Eng. Pat. 17,870 of 1889; this J., 1890, 1045) emulsifies the oil first with water by bringing the two liquids in streams into a rapidly revolving basin, and then adds the alkali solution. Air agitation is also practised, but it is not very desirable.

Considerable difference of opinion exists as to whether better results are obtainable with horizontal or vertical agitators. I have obtained the best results from very poor oils by horizontal agitators. In any case the agitation should not be below 15—20 revolutions per minute and should be started a few minutes before the first spraying of the alkali. This speed should be increased, if possible, till the "break-point" is reached sharply, and then continued for nearly half an hour to minimise the chances of uncombined alkali settling down in the foots.

In the final process of drying refined oil the use of the finely powdered salt in a thoroughly dry condition assists in removing traces of moisture and improving the flavour of the oil. The oil may be further treated with advantage with plaster of Paris.

At this stage the oil-crusher's work was supposed to have ended, but the large quantities of by-products that were wasted soon engaged the attention of chemists, and year after year new substances were made from them and placed on the market. It will not be possible to deal in this paper in detail with the various processes suggested by the different investigators, but I shall summarise the principles underlying their suggestions in the hope that this part of the paper may prove useful to those engaged in the industry. First in importance are the hulls, which form, as shown above, nearly 45% of the whole seed. In the decorticating process the economical disposal of the hulls forms a very serious problem. The following analyses of the hulls will be found useful in this discussion.

2. C. Beadle and Stevens; this J., 1909, 1015.

Three distinct uses of the hulls are made, viz., (1) as fertiliser, (2) as feeding stuff, (3) as raw material for paper making.

The following two analyses will show their richness as a cheap fertiliser, and as such they are largely used both in India and in America. In

the latter country they are used as a cheap source of potash manure by tobacco growers.

As a fertiliser, one ton of ashes is equal to 4½ tons of hard wood ashes (this J., 1889, 432). In regard to its use as a feeding stuff, considerable work has been done in America, where the value of this by-product has been fully established. In India the use of hulls was made popular by the Tata Oil Mill and then by the Navsari Oil Mill. The hulls are largely used in Government dairies and on farms and in large towns for feeding both cows and buffaloes. The Indian army transport and commissariat departments have also used these hulls in very large quantities with excellent results. During famines or times of scarcity of fodder this food has also been found very valuable. There has thus been created a large and growing demand for this new feeding stuff in a conservative country like India, and if a little effort is made in this country there is no reason why it should not come into favour, as it did in Germany (this J., 1909, 1017). Ground hulls mixed with molasses, as suggested by the Molassine Co. and Whalley (Eng. Pat. 7687 of 1913; this J., 1914, 498), forms an excellent cattle food, readily taken by the animals. Hydrolysed hulls have been put on the market for use in the manufacture of compound cake (Eng. Pat. 14,588 of 1904; this J., 1905, 853). The following is an analysis of hydrolysed hulls: Moisture, 10%; oil, 4.4; protein, 5.2; carbohydrate, 48.1; hydrolysed cellulose, 29.6; ash, 2.7%. Food value, 72.

Apart from these uses the utilisation of the hulls as a raw material for paper-making has engaged the attention of chemists both here and in America. The process consists mainly in the removal of colouring and resinous matter by boiling the hulls with alkali, thereby separating the fibrous matter in a condition required for paper making (cf. Bockmeyer, U.S. Pat. 759,800 of 1904; this J., 1904, 605). C. F. Cross (Eng. Pat. 8545 of 1904; this J., 1905, 288) obtained from the hulls two forms of cellulose differing in length of fibre. The longer fibre can be used in a variety of ways, but the shorter fibre is characterised by giving on hydrolysis considerable quantities of crystallisable sugar. Furfural may be obtained from the liquor, after crystallisation of sugar, by distillation with 30% sulphuric acid; Knopf and Baumwoll-Werke (Eng. Pat. 12,650 of 1905; this J., 1906, 217) suggest the use of alkalis, alkaline earths, dilute acids, alkali sulphites, calcium, magnesium, potassium, or sodium bisulphites in the boiling process. Wilbuschewitsch (Eng. Pat. 27,950 of 1909; this J., 1911, 80) passes the boiled mass into a hollander to be beaten, and bleaches the resulting pulp with sodium hypochlorite. This pulp is suitable for making rough papers and cardboard.

A very valuable contribution to this subject has been made by Clayton Beadle and H. P. Stevens (this J., 1909, 1015); a full treatment of the subject will also be found in the "Chemical News" (95, 193). In their opinion attempts to make paper from hulls by the wet method have not resulted in success. The best method, however, of separating the fibrous matter from hulls

was not the boiling and bleaching process, but the mechanical separation effected by beaters in vertical cylinders in Minck and de Segundo's machine. By this means the following results were obtained:—Husks, 65%; meal, 7%; cotton, 25%; loss, 3%. The paper obtained by this means was equal to a good quality of rag paper. The length of fibres obtained from Brazilian seed hulls was 2.27 to 3.34 mm., whereas the Indian seed only gave a fibre of half the length of the Brazilian fibre. The latter fibre was also very suitable for nitration. The palisade cells were found to be useless both for paper and for nitrating into gun-cotton. A corporation—the National Paper Making Co.—with a capital of £1,000,000, was formed in America in 1902 (Oil and Colour Trades J., 1902, 685) to make paper out of hulls. The paper pulp made by their process from hulls was stated to keep white and not turn yellow as wood pulp does. The cost of the pulp was £5 per ton against £15 for wood pulp.

Next in importance is the utilisation of foots. Longmore's work, mentioned above, details the process of separating the soap from the colouring matter. The niger, that is the extremely offensive smelling liquid containing most of the colouring matter and albuminous substances, has been investigated thoroughly and the claim that the colouring matter can be used as a valuable dye has not been substantiated. D. Wesson (this J., 1907, 595) has shown that this dye is of no value when compared with cutch and catechu. The colouring matter, however, combines with both nitrosodimethylaniline and nitrosodiethyl-aniline, forming dyes which give yellow-brown shades on cotton and wool mordanted with iron, chromium, and tin (Marchlewski, Wilson, and Stewart; this J., 1897, 530). These dyes are insoluble in water. On sulphonation of the gossypol and combination with α -nitroso- β -naphthol in concentrated sulphuric acid solution, a product is obtained which dyes mordanted or unmordanted wool brown.

Wesson gives the following analysis of foots: water, 36%; fatty anhydrides, 48.5% (fatty acid, 50%); glycerol, 3.98%; caustic soda, 3.20%; colouring matter, 2.42%; organic matter, 5.80%. The fatty substances are removed by heating and further addition of caustic soda. The resulting liquors contain a large proportion of colouring matter, organic matter, and glycerin. On acidifying, the colouring matter is precipitated, and there remains in the liquor a quantity of glycerin which can be recovered by the usual methods. The peculiar offensive smell, similar to decomposed fish, in the niger is due to methylamine (Wesson, *loc. cit.*). Wesson, has also noticed the fermentation of foots due to the presence of over 40% of water, especially in hot weather. I have had considerable difficulties in the handling of foots in a warm climate, as at Bombay, where the strongest casks were unable to resist the fermentation of foots. This fermentation was found mostly in foots from very poor qualities of seeds. J. Wolff (Ger. Pat. 20,483; this J., 1883, 182) prepares a leather-like substance from foots by mixing the dry foots with non-volatile solvents such as grease, oil, paraffin wax, etc., in various proportions, and with powdered mineral substances like black lead, vermilion, etc.; the mass is then heated with sulphur or carbon bisulphide. Loeschigk (Ger. Pat. 220,582 of 1909; this J., 1910, 610) prepares by the oxidation of foots an amorphous resinous substance resembling shellac. An American Co. in Savannah makes paint of dark green, red, and black colours from foots for covering roofs and exposed surfaces; thousands of gallons of this paint are sold in the Southern States at 75 cents to \$1 a gallon (Oil and Colour Trades J., 1909, 21). The method of utilising the foots mostly adopted is, however, the distillation process, by which the

Indon.

most important constituent of the foots, viz., the fatty acids, is obtained in a very good condition for making soap stock. In this process the mucilage is first acidified, the oily layer of fatty acids separated, and then distilled separately after one or two washings to remove traces of mineral acids.

It remains now only to mention the use of lint separated in the preliminary process. This lint is used in paper making, in the making of cotton-wool for surgical dressings, in the manufacture of gun cotton, celluloid, artificial silk, and a number of other articles in which cheap fibre of a good quality without regard to length is necessary.

Recently cottonseed cake meal has been prepared as an adulterant for flour used for human consumption. Fraps (Texas Agr. Bull. No. 128, 1910; this J., 1910, 972) shows that the meal freed from hull is of pleasant odour and sweetish taste, and contains 48% protein, 12% fat, 23% sugar (raffinose), 4% fibre, and 5.5% ash. It is richer in protein than meat, which it resembles more in composition than cereals. Bleaching agents used in the whitening of flours improve the appearance of this meal.

Before concluding, I will mention a few of the problems which require to be solved in connection with this industry, especially in reference to Indian seeds. The Indian seed is generally lower in oil content than the American or Egyptian, but it has been found that seed from the Central Provinces, where the rainfall is less than in Surat and Broach districts, has a higher oil content. This matter requires careful investigation with a view to obtaining an Indian seed richer in oil. From a large number of analyses of Indian seeds it is also found that the increase in the oil content of seeds is obtained with a lower percentage of cotton fibre. This also requires investigation. The fluorescent substance found in Indian oils should be isolated and a means of separation determined. Garner, Allard, and Foubert (J. Agr. Res., 1914, 3, 227; this J., 1915, 236) have noticed the effects of nutrition of cotton plants on oil content and size of seeds. This matter also requires further investigation, especially in the case of those Indian seeds which have so low an oil content. These authors have found that the addition of a complete fertiliser to an unproductive soil causes a larger cotton seed to be produced with an increased percentage of oil.

Another matter for investigation is the effect of crude cotton oil on press cloths of different types. The expenditure on press cloth forms one of the chief items in the total cost of crushing, and the high consumption of press cloth in the pressing of this oil calls for investigation. Our experience in India is that the consumption of press cloth under the Indian climatic and other conditions is 2 to 2½ lb. per ton. This is certainly 2 to 3 times higher than in this country.

Unlike other oil-pressing industries, the cotton seed oil industry is essentially a chemical industry, and its future development rests with the chemist more than with the engineer. The future of the industry in this country is also of a very doubtful character. The great progress of this industry in America, where there are nearly 900 mills, as compared to 25 to 30 mills in England, is due mainly to the favourable conditions arising from natural causes. The case of England is different; it has to depend for its raw product on foreign markets like Egypt and India. In Egypt this industry has made great progress. Nearly one-third of the crop is pressed, and oil exported to Turkey, England, and other countries. The quantity pressed in India is negligible, but there is an ever-increasing trade with this country in the seeds. This trade is looked upon both by the Indian Government and the public as a great economic drain on the country. That the Indian

Government is fully alive to this impoverishing of the agricultural resources of the country can be seen from the efforts made to promote the oil pressing industry in India. When, year after year, the cotton fields are deprived of their fertility by the inadequate return to the soil of fertilising materials by the poor peasants, the question assumes a serious aspect. The cost of production of cotton per acre is Rs. 21, of which nearly Rs. 6 is spent in fertilisers: the peasant invariably tries to do without it, with the result that in five years the production of cotton begins to decline. Therefore in the interests of the cotton growers the fertilising constituents of the seed must be retained in the country by pressing the seeds in India itself, and only foreign trade in the oil be permitted. British manufacturers have gone out to foreign countries for their requirements, and they will sooner or later have to come to India for their oils. Typical instances in which British enterprise has been obliged to found industries in the countries of origin of the raw materials are palm oil, tea, rubber, indigo, coconut oil, tobacco, jute, etc. The same will happen in the case of this industry.

The following notes will explain the photomicrographs:—

- A. Epidermis—outer skin of the seed which has no fluff on it in the "naked" variety of seeds like the Egyptian.
- E. Perisperm—a loose thin skin which separates the hull from the kernel and which makes possible the separation of the hull after decortication.
- O. Outer brown coat, containing the colouring resinous matter.
- I. Inner brown coat, also containing the colouring resinous matter.
- P₁. Palisade cell—outer portion mainly pure cellulose.
- P₂. Palisade cell—inner portion mainly lignified cellulose.
- K. Cotyledons containing oil cells.
- C. Cells containing resinous colouring matter surrounded by mucilaginous walls. The colouring matter of the crude oil and the mucilaginous substance found in the foots are derived from these cells.
- DM. Damaged hull.
- R. Radicle.
- F. Fluff or lint.

The photomicrographs are of the following varieties:—(1) American, (2) Egyptian, (3) Sea Island, (4) Brazilian, (5) Indian.

DISCUSSION.

Mr. J. ALLAN was not inclined to accept the suggestion that the fishy odour and characteristic fluorescence of Indian cotton seed oils were associated. From examination of a large number of cotton seed oils he had ascertained that it was not infrequent to find Indian oils which gave a pronounced "hexabromide" reaction, indicating the presence in the oils of at least 2½% of fatty acids of the linolenic type. Fatty acids of that kind were peculiarly prone to oxidation, and on exposure to the atmosphere developed a fishy odour, as also did linseed oil. Assuming that such unsaturated acids existed in Indian cotton seed oil, attempts to refine it by ordinary methods so as to procure a perfectly odourless edible oil would probably prove unsuccessful. The difficulty Mr. Vakil had noticed of refining Indian oil was undoubtedly contributed to in a considerable measure by the defective character of the manipulation of the seeds. If seeds could be obtained in a whole state before they were treated for the expression of the oil the resulting product would be of much better quality. The disruption of the cells and the admission of air to the kernel was undoubtedly provocative of fermentation which set up hydrolysis of the fats. Refining necessitated the removal of the whole of the free acidity of the oil and consequently the loss increased as the acidity became greater.

Professor E. KNECHT said he had been for some years associated with Mr. Hunt in an investigation on the colouring matter in cotton seed oil and the question of its possible commercial value. He had formed the opinion that the colouring matter

did not possess tinctorial properties which could be regarded as of any value on the commercial market. Did Mr. Vakil use an emulsifier or "smasher" working at a high speed for his emulsifying process? He would also like some information as to the effect of hydrogenating on the smell of Indian cotton seed oil.

Mr. L. G. RADCLIFFE said it was well known that oxidation increased the fishy odour of cotton seed oil. Both Indian and American cotton seed oils were "blown" with air for the purpose of thickening them; "lardine" was manufactured by this means. Lardine was used for thickening and mixing with mineral oils to form lubricant. The so-called "blown" or "thickened" oils made from Indian oil were easily distinguishable from those made from American oil by the increase in their odour, and when mixed with mineral oil and used on a hot bearing the smell was nauseating. In the "blowing" of both Indian and American cottonseed oils, the products that were apparently volatilised were distinctly toxic, making the workpeople very sick.

Mr. F. H. TERLESKI said that owing to careless ginning British farmers had in the past formed a prejudice against oilcake prepared from Indian cotton seed as it caused the cattle to suffer from digestive troubles. If any attempt were made to export the meats of the seed the result would be even worse as fermentation would set in. This had been clearly shown to be the case with regard to castor oil seed. It was possible that legislative action might effect improvement.

Mr. WILLIAM THOMSON enquired whether American seed could be cultivated in India.

Mr. VAKIL, in reply, said he had dealt fully with the points of odour and fluorescence of the oil in his paper. The suggestion to get rid of the fishy odour by hydrogenation of the unsaturated fatty acids was a good one, though he had no personal experience in that direction. He quite agreed that the tinctorial value of the dye product was practically nil from the commercial point of view. The toxic properties of choline and betaine found by Maxwell (this J., 1892, 372) in the oilcake had no bearing upon the subject matter of the paper and had therefore not been referred to. There was certainly a bad effect in the case of young cows and other animals, but what the result would be with human beings he was not able to say. The oilcake meal had been officially recommended by the American Government as a good substitute for meat and as a wheat diluent. He had not adopted the "smasher" process, the tests being merely on a technical laboratory scale. He had not suggested that the meals alone should be exported, though this was done to a large extent locally in America. This method of exportation was attended by certain disadvantages. The rapid oxidation of the oil in the meal, and the possibility of the meal being exposed to moisture and variations of temperature during transit, made the trade a very risky one. If climatic conditions permitted, and the distance from the decorticating plant to the oil presser was not very great, such a trade was possible. Indian peasants held their land on a tenure somewhat similar to the English leasehold, and this resulted in a considerable amount of laxity in returning the fertilising constituents to the ground, there not being the incentive of proprietorship to keep it at as high a state of fertility as practicable. The British Government had encouraged the planting of American seed in India, but much yet remained to be done in that direction. This was evidenced by the discussion which took place at a recent meeting of the Imperial Legislative Council in India, the Government being urged to take immediate steps to secure the improvement of

the Indian variety, not only with regard to fibre which was short, but also to raise the standard of the growing quality.

Communications.

A MODIFIED SOXHLET EXTRACTOR.

BY D. F. TWISS AND W. MCCOWAN.

On account of the fragile nature of the ordinary Soxhlet form of continuous extractor, a modification was desired which should be stronger and better capable of resisting hard use, and after considering various possibilities the arrangement represented in the diagram was adopted.

There has since been brought to our notice a description of a similar idea published many years ago by Blount (Analyst, 1888, 13, 127), of which we were in ignorance, but as the present form possesses one or two additional advantages, a brief description may be useful.

In Blount's apparatus there are two or more apertures of indefinite size by which the vapour passes into the inner compartment. In the modification now described, only one aperture, A, is recommended, of approximately 0.7 cm. diameter; this restriction causes a very slight excess of pressure and temperature in the outer jacket, sufficient, however, to maintain the liquid in the extractor cup in gentle ebullition.

Another advantage is that whereas in Blount's extractor the double jacket extends right to the top, in the form now represented the double jacket is shorter and the neck formed by an additional glass collar. Apart from the fact that this type of neck is stronger and may be still further strengthened by making the single neck of stouter glass, the smaller surface of the outer jacket causes a reduction in the amount of air-cooling by which vapour is condensed before it can reach the entrance aperture, A, to the inner extractor cup, and so renders the extractor somewhat more rapid in action.

The tendency of the extractor to roll when placed on the working bench can easily be checked by tightly fitting a suitably bored square piece of stiff rubber or cardboard over the neck just above the outer jacket.

That this type of extractor can give very satisfactory service has been proved by a thorough test in the chemical laboratory of Messrs. the Dunlop Rubber Company, to whom we are indebted for permission to publish this note.

THE ESTIMATION OF FREE SULPHUR TRIOXIDE IN FUMING SULPHURIC ACID BY TITRATION WITH WATER.

BY R. G. PARKER, B.Sc.

The following appear to be the methods used or suggested for the estimation of free sulphur trioxide in fuming sulphuric acid:—

1. Titration with standard alkali.

2. Measurements of viscosity.
3. Measurements of electrical conductivity.
4. Measurements of specific gravity.
5. Measurements of rise of temperature on dilution.
6. Titration with water.

No. 1 would appear to be the most generally used, but has the disadvantages:

- i. That the standard solution has to be carefully prepared and standardised.
- ii. That every error is multiplied approximately four times in the final result.
- iii. That a correction must be made for the acidity due to dissolved sulphur dioxide.

It therefore becomes very possible that under ordinary conditions the content of free sulphur trioxide is determined with no greater accuracy than $\pm 0.5\%$, and in some cases this limit of error is considerably exceeded.

Sulphuric acid of 100% strength does not fume at the ordinary temperature, but commences to do so at 30° – 40° C.; it is therefore possible to estimate the free sulphur trioxide in the fuming acid by adding water until the acid just ceases to fume when damp air is blown on to the surface.

After the experiments described below had been carried out it was found that the method was, in fact, not new; it has been described by Setlik (Chem.-Zeit., 1889, 13, 1670), but Lunge's remarks on it ("Sulphuric Acid and Alkali," 4 Ed., Vol. I., Pt. 1., p. 366) would lead one to suppose that the method was not sufficiently accurate for fairly exact work.

It was found, however, that the end-point which could be obtained in this way was exceedingly sharp, and that series of titrations of the same sample could be obtained, showing a maximum difference of 0.025 c.c. of water required.

Method of procedure.

For an acid containing 20–40% of sulphur trioxide, 50 to 75 grms. is a convenient amount. This is weighed into a 50 c.c. stoppered cylinder of thin glass (a large stoppered test tube is most suitable). In weighing, a rough balance only, weighing to 0.05 gm., is sufficiently accurate. Distilled water is then run in slowly from a burette, with frequent vigorous shaking. After each shaking the white fumes, which increase on the addition of water, are completely absorbed. The cylinder is then opened, and air blown through a glass tube on to the surface of the acid. While any free sulphur trioxide remains, this will cause fuming, which decreases towards the end of the titration, and suddenly vanishes. The operation must be carried out in a good light; and the temperature of the acid must be kept below 45° C.

If 50 grms. of fuming acid requires 3.55 c.c. of water, then the free sulphur trioxide present is

$$3.55 \times \frac{80}{18} = 15.78 \text{ grms.}$$

and the acid contains 31.56 % of sulphur trioxide. Assuming a possible error of 1 drop (that is 0.05 c.c. for the burette used) or ± 0.025 c.c., this result becomes $31.56 \pm 0.22\%$.

The estimation can be made very rapidly, but more important advantages are:—

1. Absolute accuracy of the standard used, namely, water.

2. The fact that the sulphur trioxide is titrated directly.

3. Avoidance of the necessity of estimating the sulphur dioxide present to apply a correction.

Repeated titrations of the same sample agree very closely, as shown by the following results for four different ones.

Sample I.			Sample II.		
Acid.	Water.	Sulphur trioxide.	Acid.	Water.	Sulphur trioxide.
grms.	c.c.	%	grms.	c.c.	%
88.9	6.03	30.15	50	2.45	21.8
44.45	3.00	30.0	50	2.45	21.8
50	3.36	29.9			
50	3.36	29.9			
By another observer.					
50	3.38	30.1			
100	6.78	30.15			

Sample III.			Sample IV.		
Acid.	Water.	Sulphur trioxide.	Acid.	Water.	Sulphur trioxide.
grms.	c.c.	%	grms.	c.c.	%
50	2.74	24.37	50	2.48	22.05
50	2.75	24.45	50	2.47	21.95
50	2.72	24.40	50	2.47	21.95
50	2.72	24.40	50	2.46	21.88
50	2.72	24.40			
50	2.75	24.45			

In order to ascertain the magnitude of the error caused by undue rise of temperature, three titrations were made, using 75 grms. of Sample I. and omitting cooling; the titrations were carried out fairly rapidly, and the temperature of the acid rose through a maximum of 90° to a final value of 80° C.

Apparent content of sulphur trioxide in Sample I. at 80° C.

		Error.
75 grms. = 5.42 c.c. H_2O .	Sulphur trioxide = 32.1%	+2.1% SO_3 .
75 grms. = 5.40 c.c. H_2O .	Sulphur trioxide = 32.0%	+2.0% SO_3 .
75 grms. = 5.35 c.c. H_2O .	Sulphur trioxide = 31.7%	+1.7% SO_3 .

Lunge (*loc. cit.*) states that Setlik's results differ by as much as 0.9 % for the same sample, and therefore that the method is only suitable for internal use in a works, and not when buying and selling. The experiments here described, however, indicate that the method is much more accurate than this, being probably more accurate than the average results obtained with standard alkali.

Comparison of alkali and water titrations.

In order to compare the results obtained by this method with those obtained by the usual method of titration with standard alkali, one sample (No. IV.) was titrated with freshly prepared N/1 sodium carbonate solution; the graduations of the burette used were carefully checked.

	Acid.	N/1- Na_2CO_3 required.	Sulphur trioxide.
	grms.	c.c.	%
1	2.1830	46.75	21.6
2	2.2228	47.55	21.3
3	0.5947	12.73	21.95
4	1.7578	37.64	21.96

If in the fourth titration 37.598 c.c. of sodium carbonate had been used, this would have agreed with the second titration. The largest difference is therefore $37.64 - 37.598$, or, 0.042 c.c. (which is equivalent only to one drop) in about 40 c.c. The mean result is 21.70%.

The two methods, when carefully employed, give therefore substantially the same value for the free sulphur trioxide. (The above value is not corrected for the sulphur dioxide present, since this was found to be only 0.015%.)

The author's best thanks are due to British Dyes, Ltd., for permission to publish the above results.

DETERMINATION OF THE NITROTOLUENES.

BY E. KNECHT.

In a paper delivered before the Nottingham Section of the Society by Mr. Colver and Dr. Pridcaux on the estimation of the nitrotoluenes (this Journal 1917, 180), reference is made to the process worked out by Miss Eva Hibbert and myself for the estimation of nitro compounds by means of titanous chloride, but the authors discarded it, firstly because they considered it "more than doubtful" whether reduction could take place in the presence of alcohol, and secondly that titanous chloride was not always obtainable at short notice.

The authors are not justified in their first objection and adduce no evidence in its support. As a matter of fact we have found that the method gives theoretical results in the cases of nitrobenzene and *p*-nitrotoluene. With regard to the second objection, neither we nor anyone else that I know have had the slightest difficulty in obtaining titanous chloride, which the makers supply *gratis* for scientific or analytical work.

Our process has been in extensive use for some years for controlling the composition of nitro compounds and is not only rapid but *quantitative*, giving results which can be relied upon within the ordinary limits of accuracy in volumetric analysis. The detailed results of our work in this connection have not been published for obvious reasons.

Industrial Notes.

REPORT OF H.M. INSPECTORS OF EXPLOSIVES FOR 1916.

[Cd. 8609.]

The Inspectors report that there has again been a large increase in the number of licensed factories, 23 having been added during the year, making a total of 48 factories added since the outbreak of war. The general condition of the factories, having regard to the exceptional circumstances now obtaining, is highly satisfactory. There has been considerable difficulty, however, in impressing on the picric acid manufacturers the necessity for strict observance of the requirements in regard to cleanliness and freedom from grit in danger buildings. These factories, as a rule, are offshoots of chemical factories which are of necessity difficult to keep clean, and this, no doubt, has a tendency to cause slackness on the part of employees when they are transferred to the picric acid works. Many cases of excessive quantities of picric acid being present in packing sheds have also come to notice.

In March a Committee was appointed to test the value of dry powder fire extinguishers as compared with water and other first-aid fire appliances for extinguishing or effectively controlling fires such as are likely to be caused by bombs. The general conclusion arrived at by the Committee was that a plentiful supply of water is by far the best extinguishing agent, and that dry powder extinguishers are practically useless for extinguishing or effectively controlling fires likely to be caused by bombs.

Reference is also made to the appointment of the Committee on Dissolved Acetylene (see this J., 1916, 1097).

The Chemical Advisers to the Department report that the total number of samples examined during 1916 amounted to 306 only, about the same as in 1915. The total number (53) of rejections was fairly normal, but the number (35) of rejections for faulty composition was somewhat high. This is, no doubt, partly due to the increased complexity of permitted explosives as a whole, but also, possibly, to some extent because, owing to war work, the manufacturers have not the time for quite such careful supervision of blasting explosives as before. The use of sodium nitrate in the place of potassium nitrate still appears to be causing some difficulty in connection with the heat test, but not to such an extent as last year. The number of new explosives examined (15) was the smallest for a good many years, and consequently the number of samples examined in connection with the Home Office Testing Station was also very low.

The total number of accidents with explosives reported during the year is 511, as compared with 485 for 1915. Of these, 363 occurred in manufacture, causing 195 deaths and injuries to 598 persons; no less than 144 deaths were due to two accidents, namely, 106 in one accident on the 2nd April, and 38 in another on the 21st August. Of the remaining 51, seven were killed at the Roburite Works on the 15th May, and seven at the Rainham Factory on the 14th September, and it is hardly too much to say that all these 158 fatalities might have been avoided if, instead of engaging in futile efforts to extinguish the fires, the factory officials concerned had cleared everyone away from the neighbourhood. Of the 363 accidents, 146 caused no loss of life or bodily injury, and of those injured a very large proportion received very trifling wounds.

In connection with the conveyance of cordite paste from one factory to another, a proposal was made by those chiefly interested that, instead of being packed in wooden barrels, this material should be forwarded in packages, each consisting of a double bag, the outer one being of stout canvas and the inner of a waterproof insertion material. The reasons given for this suggestion were, first, that barrels are now difficult to obtain, and, secondly, that after arrival at the factory, the barrels are the more dangerous to handle in contact with the very dusty explosive. The question was very carefully considered with special regard to the danger of freezing in cold weather, and it has been finally arranged that the vans in which this material is consigned by rail shall be steam-heated under conditions which will eliminate all danger from overheating, and this arrangement appears to give satisfaction.

In November, Messrs. Dupré carried out some tests to ascertain whether the addition of 2 or 3% of moisture to a fulminate composition would appreciably diminish its sensitiveness and render it safer for filling detonators than the dry composition. The results of their experiments indicated that the addition of as much as 5% of moisture to a mixture of fulminate of mercury and potassium chlorate gives no practical increase of safety either against explosion by shock or communication of the explosion of a portion of the mixture to the remainder, and that such mixtures should be treated with the same precautions as are usual when dealing with dry fulminate composition.

CHEMICAL INDUSTRY IN CANADA.

Addressing a meeting of the American Chemical Society at Kansas City on April 12th, 1917, Mr. H. E. Howe said that in one locality of Canada, destined to become an electro-chemical centre of some magnitude, there will ultimately be available

approximately 500,000 24-hour horse power. Here acetone is being made by a new process and the production of metallic magnesium in quantity is going forward, the metal being supplied in bars and also in the variety of powders so necessary on the battlefields to-day for star shells. Aluminium, and carbon electrodes are also made, and other chemical products are now under consideration.

Explosives are being produced on a large scale. Trinitrotoluol is produced at one plant by a process involving crystallization from a medium which yields crystals of great uniformity and unusual purity.

Heavy chemicals are produced in sufficient quantities, the plants being located principally in the Province of Ontario. Sufficient potassium chlorate to meet the requirements, together with a considerable supply of phosphorus, are produced, utilising hydro-electric power. There is the usual by-product recovery from coking plants. The electric furnace and electrolytic industries are established in Canada, producing bleach, caustic, cyanamide, abrasives, and carbides. Ferromolybdenum is manufactured in the electric furnace, and in many localities the electric furnace has been brought into play in the production of steels. Steps have been taken for the electrolytic refining of nickel matte produced in Ontario (see this J., 1917, 490).

In pharmaceutical chemistry a large number of the finer preparations are manufactured in Canada. Phenacetin has been produced since the war started, as has also acetylsalicylic acid; there is one plant with a capacity of over a ton a day making acetylsalicylic acid. *p*-Aminophenol is also being produced. Bismuth salts, iodine preparations, resublimed iodine, iodides, and iodoform, are being made in quantities sufficient for domestic use as well as for export. Hydrogen peroxide by the barium process is manufactured in quantity, and many sodium and potassium salts are purified and recrystallised. Alkaloids are prepared, and salvarsan of a grade equal to the best German product is now being prepared commercially. Aniline, phenol, and salicylic acid may be added to the list.

A few dyes are now being made in Canada, but the economic conditions are such as to make it improbable that any extension of the work can be carried out.

In regard to research, mention is made of the Advisory Council on Scientific and Industrial Research appointed by the Government, and to the work being carried out by the Forest Products Laboratory (see this J., 1916, 255).

Under the auspices of the Canadian Pacific Railway, a survey of the natural resources is being made in order that data regarding them may be made quickly available for practical application and for those interested in industrial development work.

The question of utilising plants which have been erected primarily for war purposes, when peace comes, is receiving attention. The production of nitrates from the air is strongly advocated, especially in those locations where plants have their own hydro-electric development works.

In regard to agriculture, many problems will present themselves relative to preparing the produce from mixed farming, in order that it may reach the markets in a condition to command a good price. Methods for drying to avoid high freight costs enter in, as well as the establishment of suitable plants in the vicinity of growth to work upon products of agriculture as raw materials.

In 1916, nearly \$22,000,000 worth of paper was exported from Canada, of which 88% went to the United States; the daily production of sulphite pulp approaches 1500 tons daily and that of paper exceeds 2000 tons daily. There is considerable

activity in hardwood distillation, and the Forest Products Laboratory is now carrying on softwood distillation experiments, hoping to produce oils suitable for use in the oil flotation processes.

The minerals of Canada already yield an annual income approaching \$200,000,000, and yet vast areas have not been prospected. Many of the deposits are inaccessible at present. There is said to be one deposit of gold-bearing gravel in British Columbia containing 3,000,000,000 cubic yards running 10 cents per yard. The geologist of the Stefansson expedition reports an ore body of 6,000,000,000 tons bearing copper distributed through the mass, in a quantity, however, which is not commercially attractive, but the indications are that more careful prospecting will disclose concentrations that may make it feasible in future to commence mining operations on the shores of the Arctic Ocean. The wonderful mineral resources of Northern Ontario are just being uncovered, while in the vicinity of Cobalt another gold mining camp is already establishing itself. The nickel deposits in the vicinity of Sudbury, Ontario, are also a part of the great Pre-Cambrian Shield which conforms to Hudson Bay and which continues into practically unexplored portions of the extensive Province of Quebec. Eighty per cent. of the world's supply of asbestos is mined in the Province of Quebec. Canadian apatite cannot be mined by steam shovel as are the phosphate deposits in Florida, and consequently at present it is not a commercial factor but may be looked upon as a reserve supply of this important substance. Some of the material contains from 83 to 87% phosphate, but it is enclosed in a hard Laurentian rock; that now used for phosphorus compounds of a chemical grade occurs with the mica and may be considered a by-product of this industry.

There are two varieties of soda rock which are interesting as being nearly identical with the German phonolith extensively used in the manufacture of Apollinaris water bottles. It is high in soda, contains very little iron, and approaches a natural fused glass in its composition.

Canadian magnesite has already come to the aid of steel manufacturers in providing a satisfactory refractory and is the source of much of the magnesium now made in the United States as well as all of that made in Canada.

The water powers of Canada are more abundant than in any other country; 1,712,193 24-hour horse power has been developed, and of the 18,000,000 24-hour horse power which is in sight 8,000,000 is within reach of present markets. In the central portion of Canada 2,000,000 sq. miles of territory lies at an average elevation of 1500 ft. This area drains into rivers emptying into the St. Lawrence or the sea and affords water power of dimensions difficult to compute. There are water powers which can be developed at a price per horse power which may make it possible to produce nitrates from the atmosphere in competition with the low prices in Norway.

At present the domestic fuels in use are principally the coals of eastern and far western Canada, including the anthracite in the vicinity of Bank Head, Alta. The tremendous tonnage of lignite which exists in Alberta, Saskatchewan, and Manitoba, has been limited in its use, due to its slacking during drying, but work is now under way which gives promise of making this lignite a satisfactory fuel for power purposes and the prairie provinces thereby more attractive for fields of industry. Research work looking toward the utilisation of cereal straws for fuels in certain areas is also under way with considerable promise of ultimate success. There is also a great quantity of oil shale in New Brunswick and smaller deposits in the western provinces which may be considered reserve supplies of oil.

STEELS USED IN AERO WORK.

Dr. W. H. Hatfield, in a paper read recently before the Aeronautical Society, dealt with the steels used in aeronautical construction, their composition and properties, methods of testing, and thermal and mechanical treatment. He emphasised the importance of using high-class material and of employing scientific methods in works practice. Accurate heat-treatment, based on the thermal phenomena associated with each steel, is essential, and this necessitates in works practice the use of satisfactory and properly standardised pyrometers. The best types of furnace, efficiently constructed and worked, are also required if homogeneous results are to be anticipated in the final product.

Though it has often been pointed out that the term "factor of safety" is misleading, yet its erroneous use continues. A true "factor of safety" should be the ratio between the stress which may be safely applied indefinitely under the actual working conditions to the stress actually employed. The actual values of this factor employed in modern design have been arrived at largely by the method of trial. Better results might be obtained, and fewer mysterious failures result, if the various contingencies to be allowed for were carefully examined and the "factor" placed on a more definite basis.

Among these contingencies is low elastic limit as compared with maximum stress. The difficulty of measuring the true elastic limit militates against this fundamentally important figure being determined as frequently as it should be. Our ignorance as regards the properties of steels below the yield-point is considerable, while of the properties between the yield and the breaking stress it is still greater. Variation of temperature, too, has a marked influence upon the physical properties of steel, and the influence of the ranges of temperature to which the parts have to be submitted in practice should be carefully studied. Corrosion might be carefully and profitably considered, particularly as regards seaplanes. Other items which require attention are the internal stresses left after forging and probably also after heat-treatment, and non-uniformity of material, especially as regards conditions produced by unskilful methods of manufacture and heat-treatment. Inclusions of slag, exaggerated sulphide inclusions, defects caused by unsatisfactory treatment in the forge, and last, but not least, hardening cracks, are also extremely important.

Parts not subjected to shock should be produced from material having a high elastic limit with just sufficient ductility to ensure non-brittleness, whereas for parts subjected to severe shock toughness is the more important feature. The division between these two classes of stresses is not very sharp, and in many cases a compromise would appear to have been made between two types of material. All the parts under consideration are of relatively small section, and lend themselves to very careful heat-treatment.

There is such wide divergence of opinion as to the best constructional material for pistons that cast-iron, steel, and even aluminium alloys are all in use at the present time. The author records having had definite indication that piston-heads had spent a considerable time in service above the critical point, 730° C. Generally speaking, the fluctuations of temperature during a cycle of operations take place too rapidly for such changes materially to affect the temperature of the piston or cylinder walls, except just at the skin of the material. The possibility of attainment of extremely high local temperatures at the skin depends largely on the thermal conductivity and specific heat of the material, high values in these tending to reduce the fluctuation in temperature.

For many steels the yield-point is not a definite value. If yield-point is to be taken as a guide as to the value of "true elastic limit," and if elastic limit is to be taken as the basis of design, then this quantity must have much more attention than it usually receives.

The use of impact tests of the Izod and Charpy type is not justified in view of the anomalous results obtained in practice. The torsion test is of particular interest to aero engineers, since any shaft which transmits power suffers torsion, and the natural way of testing the strength of such a shaft or of the material of which it is made should be by torsion.

In discussing the properties of a number of typical steels used in aero work, the author described air-hardening steels as extremely important, and predicted that when they are more completely understood they will be used to a much greater extent than at present. An air-hardening steel heated to temperatures of 800°—850° C. and allowed to cool in air will have great hardness, whereas the hardness introduced by the same treatment in an ordinary carbon or even a high-tensile steel is in no way comparable. It is the presence of a high percentage of nickel, as well as chromium, that induces the specific property. Such steel, on air-hardening from 800°—850° C., gives 100 tons per square inch maximum stress and upwards, accompanied by an elongation in the neighbourhood of 10%. Such results should be extremely valuable to engineers designing aircraft parts. "Stainless steel," a low carbon steel with 11 to 15% of chromium, is air-hardening, and has the property of successfully resisting the ordinary corrosive action of the weather, change from wet to dry atmospheric conditions, organic acids, oxidising influences, and sea-water. It should, therefore, have a large application to sea-plane work. At present it is used for aero valves, and would appear to be a possible material for stream-line wires.

A considerable tonnage of sheet steel is employed in aero work, e.g., for manufacturing clips, etc. The steel used for such purposes has usually a low tensile strength, say, 28—30 tons. A higher class of sheet steel is being used containing nickel, which gives approximately 35 tons tensile with a considerably higher yield-point than the mild steel. A drawback against this latter steel is that there is some difficulty in working it.

JAPANESE GOVERNMENT INDUSTRIAL COMMITTEE.

According to *The Chemical Technology* (March issue), the Japanese Department of Agriculture and Commerce has recently appointed a Committee to institute researches in connection with Japanese industries. The Minister of the Department, M. Nakashoji, states that the work of the Committee will include a thorough examination of the natural resources of the country, e.g., coal mines, iron ores, agricultural and forest products; encouraging the further development of the chemical, textile, and other industries which have expanded so largely since the outbreak of war; collecting detailed information in regard to foreign markets with a view to the expansion of Japanese export trade; and co-operating with Government and other Committees which have for their object the promotion of Japanese industries and commerce.

SOCIETY OF GLASS TECHNOLOGY.

At a joint meeting of the Faraday Society and the above Society, held in the Department of Applied Science at the University of Sheffield on June 20th, Prof. W. G. Fearnside gave an address on "The

Resources of Refractory Materials available for Glass Manufacture." The problem of refractories was common to both the steel and the glass industries. In the manufacture of steel, furnaces were run at a much higher temperature than in the case of glass, and so from the point of view of withstanding heat, a refractory useful in steel would be quite good for glass. In the manufacture of the latter, however, the severest test on the refractory was its power of withstanding chemical action. Refractory substances are to be found in different geological formations, but many of the most used refractories are in the vicinity of coal measures. The occurrence and relative importance of various ganister and fireclay beds were discussed and their positions indicated, special mention being made of silica from Meltham, near Huddersfield, ganister from the neighbourhood of Sheffield, and fireclay from the the Halifax district. The relative values of the "Wooden Box" clay from Church Gresley, in the Leicester coalfield, of the clay from South Wales, and from Glenboig, in the south-west of Scotland, were also commented upon. The address ended with a discussion of the kaolins and ball clays of Cornwall, Devon, and Dorset.

An address on "Refractory Materials" was delivered by Mr. J. H. Davidson. The analyses of various clays were given and their likenesses and differences were discussed. In addition, a stone from Durham used in building glass tank furnaces had been analysed, together with several similar local stones. The stones differed little amongst themselves in analysis, but were widely different from clay as they contained considerably more silica and less alumina. It was shown that the percentage of water taken up by a clay in working was a measure of its plasticity, and methods of testing the plasticity of clay were given. From the numbers obtained it was found that "Wooden Box" (Church Gresley) clay was anomalous in its behaviour. The Leeds fireclay required 18% of added water for plasticity, Halifax 18½%, Stourbridge 18%, "German" 19½%, whilst "Wooden Box" required as much as 25%. Most clays contract 5% to 6% in drying, but "Wooden Box" is again unique, as it contracts 6½%. In the firing tests blocks were fired at a temperature of 1000° C., when a contraction in length of ½% to 1% was noted, with the exception of "Wooden Box," which contracted as much as 1½%. Under the same firing conditions the stones increased about 1% in length. A second firing to 1450° C. was given, and the following total contractions were observed:—Halifax clay 8½%, "German" clay 10%, Leeds clay 10%, Stourbridge clay 11%, "Wooden Box" 17%. At this temperature it was found that stones increase 3½% in length. In all the tests carried out it will be observed that "Wooden Box" clay is anomalous in its behaviour. Since clays contract so much on firing, the necessity for the admixture of "grog" in potmaking is at once apparent. In the opinion of the author, the present day potmaker uses too little "grog," and also "grog" of the wrong type. Instead of using ground broken pots, he advocated the use of fresh burnt raw clay which, although requiring great care and some trouble in preparation, would be most efficacious.

Dr. Walter Rosenhain pointed out that the desiderata of a good refractory were (1) non-solubility, (2) resistance to chemical action, (3) facility of manufacture, (4) availability, (5) correct thermal conductivity. Unfortunately all these points could not be combined in one substance. Most glasses are "acid" fluxes, and so liable to attack basic materials in the refractory. Thus it is that clays with increasing alumina content are so resistant to glasses. One great obstacle in the glass trade was the time taken in building

and drying pots, and he hoped that in the near future pots would be made by a casting process. Regarding "grog" in pot building, he was of the opinion that slate could be used as a binding material and to alleviate shrinkage, giving as it would a sharp-edged particle and also being very refractory. He also advocated the measuring of the plasticity of clay by means of the "penetrometer." He also spoke of the virtue of coating fireclay and pot clay by specially refractory materials; in particular he mentioned the use of carborundum and of zirconia as being likely to yield satisfactory results.

Dr. P. G. H. Boswell spoke of the need of further investigation in the behaviour of pot clays, and hoped that glass manufacturers themselves would experiment. In addition, little was known yet as to the effect of small amounts of impurities in pot clay. For example, might not titanium oxide have a deleterious effect? He discussed the purification of clay on a large scale, and also spoke of the future of surface combustion in glass manufacture.

Mr. Spiers, the Secretary of the Faraday Society, appealed to glass manufacturers to make known their difficulties regarding refractories.

ROPINESS IN BREAD.

Since the Government regulations in regard to the milling of wheat and the addition of other materials to wheat flour came into force, complaints of the inferior quality of the bread have been rife. That bread made with flour of the type now used should be particularly susceptible to ropiness is what might have been anticipated from consideration of the known facts in regard to this disease. The production of ropiness in bread was thoroughly investigated by E. J. Watkins some years ago, and the results of the investigation were communicated to the London Section of the Society (see this J., 1906, 350). In view of the Government regulation that bread must not be exposed for sale until it is at least 12 hours old, it is important to note that the disease usually becomes evident only after from 12 to 48 hours from the time the bread has left the oven. It appears to develop at the centre of the loaf and progress gradually outwards. The bread acquires, at first, a faint sickly odour, and brownish spots appear in the crumb and gradually extend, the central portion of the loaf ultimately becoming moist and sticky, so that it can be drawn into long gummy threads. Under specially favourable conditions the disease develops to such a degree that the whole of the crumb is converted into a slimy brownish mass, having a strong valerian-like odour. Bread made from flour containing bran is much more liable to the disease than that made entirely from white flour. Watkins succeeded in isolating the micro-organism responsible for the disease and identified it as *Bacillus mesentericus fuscus* (Flügge), which is frequently found in soil and on vegetables, etc. It was shown conclusively that the bacillus is introduced into the bread by the flour, probably on the bran coating. The bacillus is a prolific spore-former, and the spores are capable of resisting relatively high temperatures for prolonged periods, and hence cannot be destroyed by baking the loaves for a longer time than usual. Increasing the time of baking, however, produces a drier bread, and is advantageous in this respect, since dryness tends to inhibit the development of the spores. Watkins found that development could be prevented completely by adding a small quantity of acetic acid to the dough, but it is doubtful whether such a method would prove acceptable. He also described a simple bacteriological test by which the presence of *Bac. mesentericus* in flour

could be detected, and recommended that when the flour was found to be contaminated it should be used under conditions most unfavourable to the development of the bacillus, *i.e.*, the dough being made slightly acid and the bread quickly cooled and kept at a low temperature and as dry as possible during storage.

REPORT ON RESOURCES AND PRODUCTION OF IRON AND OTHER METALLIFEROUS ORES.*

(Prepared for the Advisory Council for Scientific and Industrial Research.)

The Advisory Council for Scientific and Industrial Research has thought it desirable that a Report should be compiled summarising the latest information available regarding the iron ore resources of the United Kingdom as well as those of other countries. The aim of the writer of this Report, Mr. G. C. Lloyd, of the Iron and Steel Institute, has been to collect and present in a summarised form the main facts concerning the resources of iron ores and of other metalliferous ores necessary to the metallurgy of iron and steel, and to indicate their composition and character, giving as many analyses as possible of the minerals in every locality, with indications as to their geographical position and accessibility. The Report is divided into three main parts, of which Part I. deals with the iron ores of Great Britain

and Ireland and of the British Dominions. The ores of the United Kingdom are described in approximately the following order:—Red hematites, brown hematites, and magnetites (Cumberland, Lancashire, Cornwall and Devonshire, Forest of Dean); carbonate ores or ironstone (Cleveland, Northampton, Rutland, Leicester); the calcareous ores of the lower and middle lias (Lincolnshire, Oxfordshire, Wiltshire, Somerset); iron stone of the coal measures (Scotland, Northumberland, Staffordshire, Derbyshire, Shropshire, South Wales); the aluminous iron ores of Antrim, and the various smaller deposits of hematite and limonite in Ireland. A brief note is also given on the siliceous ores lately opened out in Kent. The resources of the British Dominions are then referred to, the principal deposits at present known being those of Newfoundland, Canada, India, and Australia. Part II. gives information of the same kind and as far as available with regard to most of the other countries of Europe, Africa, Asia, and North and South America. In Part III. notes are given of the principal uses, occurrence and composition of the ores of metals other than iron but used in the iron industry—namely, chromite, cobalt, manganese, molybdenum, nickel, titanium, tungsten, vanadium, and zirconium, including references to the composition of ferro-alloys manufactured from some of these ores.

For the purposes of the Report no new investigations of any special kind have been undertaken, but the most recent reports on the mineral deposits of the various countries have been briefly reviewed and references to the original sources of information have been given in every case.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Feron 8, Paris (3e.)

Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Separating immiscible liquids [oil-water emulsions]; Apparatus for.—J. L. Sands, London, and J. Gourlay, Glasgow. Eng. Pat. 106,165, June 6, 1916. (Appl. No. 7993 of 1916.)

To facilitate the cleaning and operation of the separator described in the application for Eng. Pat. 14,217 of 1914, which consists of annular filter screens that allow only one of the constituents of the emulsion to pass through, the outer casing is made removable and the discharge of the water is regulated by a float valve working in a chamber connected with the separator proper by water-sealed tubes.—W. H. C.

Conveying [corrosive] liquids in bulk; Vessel for.—H. N. Morris and N. K. Turnbull, Manchester. Eng. Pat. 106,351, June 14, 1916. (Appl. No. 8370 of 1916.)

THE claim is for an approximately cylindrical inner tank to hold the corrosive liquid, spaced apart from an outer shell which forms the body of a barge or other vessel. (See also this J., 1916, 1243.)—W. H. C.

Cooling water and other liquids; Apparatus for.—C. C. Thomas, Baltimore, Md. U.S. Pat. 1,225,889, May 15, 1917. Date of appl., Sep. 14, 1915.

WATER from a central spray producer, directed upwards, falls on to a series of superposed cooling surfaces, each in the form of a frustum of a cone,

The inclination of the conical surfaces increases from below upward and the spaces between them diminish from the centre outward. A screen of wide mesh, in the form of an inverted cone, is placed centrally at the entrance to the spaces so that the spray passes through it. Cooling air flows upward through the conical spaces over the water films.—W. F. F.

Desiccating apparatus.—C. E. Rogers, Detroit, Mich. U.S. Pat. 1,226,011, May 15, 1917. Date of appl., Oct. 18, 1913.

LIQUID to be desiccated is sprayed into a number of parallel branch conduits for hot air extending from a pair of supply pipes into a large chamber on opposite sides. The streams of hot air carrying the liquid spray impinge on one another in the chamber, and pass from it in a direction at right angles to that of their entry, into a pair of exhaust chambers, one on each side, which are exhausted so that the main chamber is not above atmospheric pressure. A pivoted screen, having an area greater than the combined cross-section of the air conduits, is mounted at the entrance to each exhaust chamber in such a way that it may be slowly displaced and then jerked back to its normal position.—W. F. F.

Grinding-ring for attrition mills.—W. Van Nostrand, Dalton, N.Y. U.S. Pat. 1,226,032, May 15, 1917. Date of appl., July 21, 1916.

MATERIAL, such as grain, is fed to the centre of a pair of coaxial grinding rings placed face to face, and passes first through a set of crushing

ribs at the inner edges of the rings. The intermediate portion of the ring is provided with radial grinding ribs and with a number of pairs of circumferential rows of grading ribs between and flush with the grinding ribs. The ribs of each pair of rows are not in alignment and the radial spaces between them diminish from the centre outwards. The material passes finally through a pair of finishing ribs at the outer edge of the rings.—W. F. F.

Tube-mill. F. E. Marey, Salt Lake City, Utah. U.S. Pat. 1,226,555, May 15, 1917. Date of appl., Jan. 18, 1917.

THE head of the rotary drum is provided with a grating fixed in position by a surrounding ring which has recesses engaging with corresponding lugs projecting from the peripheral wall of the tube-mill.—W. H. C.

Furnace or stove construction. G. C. Kidder, Salt Lake City, Utah. U.S. Pat. 1,226,082, May 15, 1917. Date of appl., Mar. 27, 1916.

A RELATIVELY large supply of fuel is fed to a pair of retorts on each side of a combustion chamber, the hot combustible gases passing into the combustion chamber. Conduits for the supply of air for combustion are disposed below the inner walls of each retort and are divided into separate chambers, one above the other, by partitions. Each air chamber is provided with openings of different sizes for discharging the air to the combustion chamber.—W. F. F.

Furnace for heating or annealing. Furnace. A. Smallwood, London, Assignor to American Incandescent Heat Co., Portland, Me. U.S. Pats. (A) 1,226,266 and (B) 1,226,267, May 15, 1917. Dates of appl., Sept. 21, 1914, and June 19, 1915.

(A) THE fuel is partly burnt in a preliminary combustion chamber, and the gases pass to a main combustion chamber connected to a heat-radiating chamber having a radiating surface extending the length of the heating chamber. The gases finally pass into the heating chamber through a number of flues connected to the radiating chamber and adjustable by dampers. (B) In a furnace as in (A) a number of heating chambers are provided with common preliminary and main combustion chambers, and a separate heat-radiating chamber for each heating chamber.—W. F. F.

Caleining furnaces; Process for facilitating the descent of the charge in—. Bergwerblische Industrie G.m.b.H., Metz. Ger. Pat. 297,115, May 29, 1915.

THE furnace consists of a vertical shaft with a water-cooled tube of diamond-shaped section fixed transversely near the base. At intervals water is driven out of this under pressure into the body of the hot charge, which is thereby suddenly chilled, and broken up into small pieces, which readily fall down to the discharge openings.

—H. J. H.

Measuring and mixing device. G. J. Olney, Westernville, N.Y. U.S. Pat. 1,226,108, May 15, 1917. Date of appl., Feb. 7, 1916.

TWO separate hoppers are mounted over openings in a cylindrical casing, within which a cylinder provided with measuring pockets rotates. The pockets are filled as they pass under the hoppers and emptied as the cylinder rotates. Liquid is fed by a pipe into the hopper feeding one series of pockets and liquid is fed by another pipe into the cylinder for the other series of pockets at a point before they reach the outlet from their hopper. An outlet is provided in the cylindrical

casing opposite the second series of pockets for the escape of air from the pockets being filled, without passing through the hopper.—W. F. F.

Mixing slimes; Process for— by means of compressed air. G. Polysius, Dessau. Ger. Pat. 296,210, June 6, 1914.

THE tank containing the slime is furnished with a number of tubes through which compressed air can be directed to different parts of the tank. By a mechanical device the air is supplied to each of these tubes in turn, so that all parts of the material are subjected to mixing action. A suitable device is a multiple-slide valve, or a multiple-way tap which on rotation brings the air supply in turn in communication with all the distribution tubes arranged radially round the tap.—H. J. H.

Lubricant. C. F. Axtell, Assignor to O. P. Amend, New York. U.S. Pat. 1,226,165, May 15, 1917. Date of appl., July 19, 1916.

THE lubricant is composed of a 30% solution of calcium chloride mixed with graphite and alcohol.—W. H. C.

Refrigerating apparatus. T. Carrigan, New York, and A. J. Sweeney, Bayonne, N.J. U.S. Pat. 1,226,186, May 15, 1917. Date of appl., May 5, 1916.

IN an absorption refrigerating apparatus, the weak liquor is withdrawn from, and the strong liquor delivered to the generator by a rotary pump, and the gaseous refrigerating agent is withdrawn from the evaporator by a pump and compressed to such a degree that it is absorbed by the weak liquor without the necessity of cooling the latter.—W. H. C.

Melting-pot. C. A. Fraser and F. M. Henry, Assignors to C. K. Spears, Minneapolis, Minn. U.S. Pat. 1,226,496, May 15, 1917. Date of appl., Oct. 19, 1916.

A MELTING pot is connected with an auxiliary melting pot at a higher level by means of a pipe provided with a valve. The latter is operated by a rod depending from one arm of a rocking bar, the other arm of which is connected by a rod with a float in the melting pot proper. The rod connected with the float is provided with a spring to give a quick "snappy" action of the valve.—W. H. C.

Precipitation apparatus. A. E. Vandercook, Oakland, Cal., Assignor to California Macvan Co. U.S. Pat. 1,226,611, May 15, 1917. Date of appl., Nov. 9, 1915.

A CYLINDRICAL precipitating chamber is mounted above a conical feed chamber from which it is separated by a perforated plate. The shredded solid precipitant rests upon the perforated plate and is compressed by a perforated weight which rests on the top of the precipitant. The liquid to be treated is delivered to the bottom of the conical feed chamber by a central pipe, rises through the precipitant, and overflows into an annular gutter which surrounds the precipitation chamber.—W. H. C.

Precipitation and separation of material from one liquid by another; Process for continuous—. E. Hausbrand, Berlin. Ger. Pat. 297,365, July 24, 1914.

THE apparatus consists of a train of vessels, those for mixing precipitant and liquid to be treated, and those to act as settling tanks being placed alternately. The liquids, well mixed, pass from the bottom of one mixing tank into the side of a settling tank where separation according to specific gravity occurs. The tanks are so arranged that the lighter liquid can rise up a pipe to a level above that of the contents of the next mixing

tank. The apparatus can thus be worked continuously, liquid to be washed and precipitant being sent through in counter-current.—H. J. H.

Distillation and the like; Column for—W. E. Lammus, Lynn, Mass. U.S. Pat. 1,226,898, May 22, 1917. Date of appl. Aug. 19, 1911.

THE column is composed of superposed sections, each being a parallelogram in horizontal cross-section. The upper and lower faces are flat except for two lugs projecting upward from two opposite faces, and two lugs projecting downward from the other two faces. The lugs maintain the units in alignment and retain the packing material in position between them. The units are bolted together by means of lugs projecting outward.

—W. F. F.

Nickel catalyst; Process of making—J. J. Burchenal, Assignor to The Hydrogenation Co., Cincinnati, Ohio. U.S. Pat. 1,226,945, May 22, 1917. Date of appl. Feb. 23, 1912.

A SOLUBLE nickel salt is precipitated by a soluble carbonate and the precipitate is calcined and then reduced whilst free from admixture with non-reducible substances.—W. H. C.

Gases; Apparatus for purification of—G. Zschocke, Kaiserslautern. Ger. Pat. 296,209, May 23, 1911.

THE washer is of the disintegrator type, the gas with a spray of water passing an annular space in which two sets of bars are disposed radially, one fixed to the outer case and the other rotating. The free ends of the bars run in grooves cut in the drum of the moving part of the washer and in the wall of the fixed case. These grooves serve a double purpose of providing a channel for the escape of the wash water thrown outwards and also a seal to prevent gas from passing through the washer untreated.—H. J. H.

Separation of foreign bodies from pasty masses prior to drying; Process for continuous—J. Jung, Cöln-Ehrenfeld. Ger. Pat. 296,228, Jan. 31, 1915.

THE pasty material is forced into the space between a revolving perforated cylinder and a plate which bears on the wall of the cylinder under the action of a spring. The pasty material passes through the perforations into the drum, while foreign bodies are carried past the spring plate and fall or are scraped off the drum. The sifted material inside the drum is forced by a screw conveyor to one end against a rapidly rotating disc where coarse particles are reduced in size and incorporated.—H. J. H.

Heat; Process for facilitating transmission of—by surfaces (boiler or condenser tubes). C. Hülsmeier, Düsseldorf-Grafenberg. Ger. Pat. 296,285, Feb. 2, 1916.

DEVICES of various kinds, made of materials of low thermal conductivity, are introduced into the current of water so as to throw it into eddies. The devices are arranged to float or are suspended loosely so that by their motion they may prevent the accumulation of boiler scale. Suitably shaped wires and strips of leather, ropes, objects of various forms, with and without vanes attached, are suggested.—H. J. H.

Treating solids and liquids with steam; Process for—G. Voigtmann, Berlin. Ger. Pat. (A) 296,596, Apr. 28, and (B) 296,597, May 6, 1916.

(A) THE substance to be treated is placed in a cylindrical vessel of porous material which acts as a filter medium. This is enclosed in a perforated case hanging inside another vessel. The whole stands in a steam boiler so that the contents

of the filter chamber are subjected to the influence of steam but under such conditions that any liquid draining out of the filter can be collected and prevented from entering the boiler water. (B) A cylindrical vessel with a belt of perforations round the walls and a filter medium above and below the perforations, is fixed inside a steam boiler. In this way material passing through the filters is subjected to the action of steam and collects finally in a chamber below, without the possibility of escaping into the boiler. By means of a wick dipping into the lower chamber, the liquid there can be raised by capillary action above the upper filter layer and so subjected to repeated steaming.—H. J. H.

Mixing and spraying of liquids; Process for intimate—M. Emmerich, Kiel. Ger. Pat. 297,271, June 25, 1912.

THE apparatus consists of a metal collar into which two tubes are screwed so as nearly to touch one another, the gap falling at the point where a circular groove is cut round the inside of the collar. The liquid under pressure is forced into this groove and escapes in a radial direction through the gap to impinge on a cylinder of hard material—glass or agate—placed axially in the tubes. It is thus broken up into a state of fine division and is turned through 90° and passes out through one of the tubes.—H. J. H.

Packing materials for absorption and reaction towers. F. Raschig, Ludwigshafen. Ger. Pat. 297,379, Feb. 19, 1916. (See also Eng. Pat. 6288 of 1911 and Ger. Pat. 292,622; this J., 1914, 907; 1916, 916.)

THE packing may be made from metal plate, strips, or tubes, of cast iron or ceramic materials, and may be used in absorption or reaction towers, still-heads, dephlegmators, mixing or heat-exchange apparatus. The packing materials, which are loosely and irregularly piled in the apparatus, may be of a variety of shapes, e.g., coils of polygonal shape such that at least two angles are not right angles; cylinders which have either one or both ends inclined to the axis; cylinders with ends of screw form, conical bodies so arranged as to prevent one from being pushed into another; double cones; or cones with inclined bases.—H. J. H.

Filter-plates. C. Greiner, Heufeld. Ger. Pat. 297,132, Jan. 6, 1916.

THE plates have either parallel or concentric circular corrugations, along the ridges of which holes are cut. Tight packing of the filter-cake is minimised, the plates are easily cleaned, and lodgment of bacterial growths is avoided.—H. J. H.

Revivifying and decarbonising bone-black and other filtering media; Apparatus for—J. Wetter, London. From M. Weinrich, New York. Eng. Pat. 106,519, May 20, 1916. (Appl. No. 7219 of 1916.)

SEE U.S. Pat. 1,181,398 of 1916; this J., 1916, 823.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Fuels; Rational utilisation of—N. Caro. Chem.-Zeit., 1917, 41, 393–395.

THE rational utilisation of fuel has excited much attention in Germany recently, especially in connection with proposals for taxation of fuel and electrical power. In some quarters the carbonisation or gasification of the whole of the coal used is advocated, with prohibition of the

combustion of raw coal. For many purposes the latter can be regarded as an unnecessary and old-fashioned process, while the former, by reason of the by-products obtainable and the hygienic and other advantages which follow, should certainly be widely developed in the interests of true national economy. A note of caution, however, is sounded against the rash generalisations from special cases which are frequently current. If all coal were carbonised or gasified, the production of by-products would exceed any demand that can be anticipated at present. After the war there will be available large supplies of synthetic nitrogen compounds which will inevitably prevent the maintenance of the price of ammonia at the pre-war level. The question of the rational utilisation of fuel is to be studied from an economic standpoint. There are cases where on this ground the direct combustion of coal is preferable and more economical in fuel than gasification or carbonisation. In carbonisation there is a thermal loss of 10–15%, in simple gasification of 15–20%, and in gasification for by-products, using steam, the loss may rise to 30–50%. These losses must be reckoned with in comparing the thermal efficiency of methods of utilising coal. As a result, the fuel consumption in raising steam or heating certain furnaces may be increased by substituting gas firing for coal firing. Nevertheless there are numerous cases where gas firing shows such marked superiority in the performance of a particular operation or sometimes an exceptional thermal efficiency, that this heat loss in gasification becomes of minor importance. Thus where cleanliness of operation is essential, or where high temperatures must be developed, or where the grade of fuel is unusually low, gas firing may be preferable. For boiler firing these factors are inoperative and no economy of fuel is normally effected by the previous gasification of the coal. Owing to the greater heat loss in the producer, gasification with by-product recovery leads to still smaller thermal efficiency in heating operations and then the choice is decided by the value of the by-products—a very uncertain factor, perhaps, in the near future. This and the lack of a supply of suitable cheap coal has militated against the development of the Mond gas process in Germany though it has established itself in a few places under specially favourable conditions. Even in England (South Staffordshire) where conditions are exceptionally favourable, the central generation and distribution of Mond gas made only slow progress for many years.

The gas engine is thermally more efficient than any form of steam engine, so that fuel economy can be effected by gasification of the coal combined with the use of the gas engine as prime mover. This economy can be increased by using the exhaust gases from the engine in the producer, when the thermal efficiency of the latter rises to 80–85% (with by-product recovery). Unfortunately the capital cost of the gas engine is so high and its flexibility under load so low that it cannot for the present compete favourably with the steam turbine for power production. This may be changed in the future especially if the problem of the gas turbine is solved. The author concludes that no saving of fuel will be achieved by central gasification and in view of the possibility of fuel taxation, proposals to carry this out at the present are premature. He regards it as preferable to allow the question of gasification of fuel prior to burning to be decided by the unfettered judgment of industry following its normal technical development. The expenditure of heat in carbonisation is less than in gasification and to that extent it can contribute more to fuel economy. Furthermore, the range of by-products is greater. Wherever circumstances—

technical and economic—permit, national economy will be promoted by this treatment of coal. It must be remembered, however, that low temperature carbonisation, liquefaction of coal under pressure by means of oxidising and reducing agents (compare Bergius, Eng. Pat. 18,232 of 1914; this J., 1916, 167), and the physical and chemical treatment of coal may possibly bring in the future new methods of utilising fuels which can advantageously be adopted in the interests of national economy.—H. J. H.

Refractory materials committee of the Institution of Gas Engineers: Report of the —. Gas J., 1917, 138, 502–504.

IN addition to work dealing with materials from different makers, the committee has found it essential to employ bricks made from known materials under exactly defined conditions. Clay from six sources, representing varieties of material found in the United Kingdom, has been obtained and bricks made therefrom under widely varying conditions in such a manner that their "life-history" is known.

The hot-to-cold measurements of bricks on the market are given in an appended report by J. W. Mellor, and the results show that the true thermal expansion is obscured by effects due to the after-expansion or after-contraction of the fire-brick occurring whilst the bricks are being measured. Tests on this after-expansion or contraction appear to show that ordinary silica bricks tend to give less expansion, and fireclay bricks greater contraction, in a reducing than in an oxidising atmosphere.

Tests on the refractoriness of whole bricks under load presented much unforeseen difficulty, and to ensure uniform temperature throughout the test-piece, a size of about 3 in. × 3 in. appears most suitable.

It has not been found opportune to make any change in the standard specifications for bricks, but two alterations have been made in those relating to retort material. Silica material is now permitted, and in addition to a minimum porosity of 18% a maximum porosity of 30% has been inserted. During the last year steps have been taken to co-ordinate the research work of various societies on refractory materials (see this J., 1917, 370).

The Council of the Institution of Gas Engineers have drawn up the following schedule of the special problems and requirements of the gas industry:—Effect of loads on refractoriness of fire-bricks. Variation in size of fire-bricks under hot and cold conditions. Study of clay for jointing. Effect of oxidising and reducing atmospheres. Effect of firing temperatures. Influence of flue dust and mineral constituents of coal carbonised. Thermal conductivity at different temperatures. Effect of admixture of silica material. Further investigation of the methods of manufacture of carbonising retorts. In respect to retort material, gas-works and coke-ovens have special requirements in that the material must withstand exceptionally rapid and great fluctuations of temperature.—J. E. C.

Peat, wood, and lignite in gas making. Soc. Technique du Gaz, June 8, 1917. Gas J., 1917, 138, 578–579.

TESTS on the carbonisation of peat at the La Villette works from 1861 to 1866 showed that 100 kilos. of crude unpurified peat yielded 45 to 50% of coke, 12% of tar, 7300 cub. ft. of gas per ton, and 38 galls. of ammoniacal liquor per ton. With purified peat the results showed 60% coke, 15% tar, 7500 cub. ft. gas, and 46 galls. of liquor per ton. Experiments were resumed in 1887 and gave results showing a variation in gas yield of 8760

to 12,191 cub. ft. per ton, and in ammonia yield from 2 to 4.1 kilos. per 1000 kilos. The proportion of carbon dioxide in the gas varied from 16 to 25%. In trials in Switzerland and Bavaria, the carbonisation of wood in cast-iron retorts gave a yield of 10,800 cub. ft. of gas per ton, 26% of good charcoal, and 5 to 7% of tar. Results of tests at Romarantin are also given (see this J., 1917, 538). When used in a pure state the wood gas required a readjustment of the burners, but when mixed with coal gas it gave good results. Wood gas contains an appreciable quantity of acid, although very little sulphur, and the proportion of wood used along with coal is limited by the condition that the acids shall be neutralised by the ammonia of the gas, or corrosion of the works plant will result. In dealing with lignite it has been found practicable to use only a retort plant of the Woodall-Duckham type, the powdery nature of the residue necessitating a low temperature for its removal from the retort. The gas contains much sulphur and carbon dioxide. Up to 15% of lignite gas with coal gas presents no difficulties in purification or consumption. As in the case of peat and wood, the nearness of a gas-works to deposits of lignite is the factor influencing the possibility of employing this material.—J. E. C.

Gas meters: Report of the Joint Committee of Institution of Gas Engineers and Society of British Gas Industries on the life of —. Gas J., 1917, 138, 504—508.

OWING to difficulties occasioned by the war, the Committee decided to suspend the branch of the investigation dealing with the chemical aspect, confining their attention to the practical and mechanical aspects. A series of questions relating to the conditions under which meters are used, tested, stored, etc., was sent to 1600 different undertakings, but only 301 replies have been received. The report of R. Lessing brings to light instances of spent oxide being carried forward from the works purifiers and being deposited in the meters, and the possibility of dust passing the meters, gasholders, and valve systems and being carried for miles in the mains is by no means negligible.—J. E. C.

Naphthalene [in coal gas]: Determination of — by picric acid. Knublauch, J. Gasbeleucht., Oct. 11 and 21, 1916. Gas J., 1917, 137, 64—66.

The author recommends the following method of determining naphthalene:—A sufficient volume of gas to give about 0.08 gm. of naphthalene is passed at the rate of 50—55 litres per hour through two wash bottles containing 110 c.c. and 25 c.c. respectively of 1% picric acid. If much ammonia is present, the first bottle is charged with a mixture of 40 c.c. of the picric acid solution, 40 c.c. of N/1 sulphuric acid, and 30 c.c. of water. The gas rate may also be raised to 80—85 litres per hour. Precipitated naphthalene picrate is filtered off, a 0.2% solution of picric acid being employed for washing; 100 c.c. of this should suffice even when sulphuric acid is present. Any particles of picrate remaining in the second bottle are washed with a little neutral water into the first to which also is transferred the filter and precipitate. Methyl orange is added and the contents are titrated with N/10 alkali. In titrating, a deduction (0.1 c.c. for an 8 cm. filter) is made for the picric acid absorbed by the filter paper. The result multiplied by 0.0128 gives the weight of naphthalene.—H. J. H.

Methane and air: Influence of pressure on the ignition of a mixture of — by the impulsive electrical discharge. R. V. Wheeler, Chem. Soc. Trans., 1917, 111, 411—413 (see also this J., 1917, 378).

THE experiments upon the ignition of a mixture of

methane and air by impulsive electrical discharge, have been extended to pressures higher than atmospheric. The results obtained by Thornton (this J., 1916, 682), when plotted, showed well-defined steps, and above 2000 mm. pressure, the direction of the stepped curve was reversed, showing a decrease in "ignitibility" of a given mixture as its pressure was increased. These observations have not been confirmed, the "ignitibility" gradually increasing until it becomes practically constant at 4000 to 5000 mm. It is suggested that Thornton's records disclose in reality merely the increased difficulty of passage of the discharge with increased pressure of the gas.—B. N.

Sulphur in petroleum oils. F. M. Perkin, J. Inst. Petrol. Tech., 1917, 3, 227—242.

THERE is a great variation in the sulphur content of oil from different regions. If combined with mineral matter in shale, etc., this portion will not pass into the oil on distillation, but if present in the "kerogen" or organic matter a considerable portion will appear in the distillate. The sulphur may be due to decomposition of vegetable or animal albuminous matter or, in case of very large contents of sulphur, may be produced by reduction of inorganic matter such as gypsum. The removal of sulphur compounds depends on their stability. They are generally distributed between all the fractions of the oil, but in greater proportion in the higher fractions, consecutive fractions from American crude oil showing the following percentages, 0.02, 0.10, 0.38, 0.41, 0.37, 0.37, 0.51. It is difficult to isolate these compounds owing to the proximity of the boiling points to those of the various hydrocarbons, and the only method of procedure, in some cases, is to combine the sulphur with some reagent, such as mercury chloride. Thiophene has been found in Russian and German oils, thiophanes, which may be looked upon as saturated thiophenes, and alkyl sulphides having been isolated from Canadian petroleum. Mercaptans seem only to have been noticed in Baku oils. Occasionally carbon bisulphide is found in petroleum. Unsaturated sulphur compounds may be removed by treatment with sulphuric acid, but under certain conditions the acid acts also on the unsaturated hydrocarbons and the method may be too costly. Moreover sulphonic acids soluble in paraffin oils may be formed, giving off sulphur dioxide on heating, and actually adding sulphur to the oil. Sulphur in petrol should be reduced to the lowest limit. Kerosene and lamp oils should be free from sulphur. Sulphur is allowable in greater quantity in fuel oils, but if present in unduly large quantities is said to cause pitting in the boiler plates and tubes. Attempts to desulphurise oil on a working scale appear to have originated in Canada in 1869. Oils from Ohio are desulphurised by cupric oxide. The volatile portion may be passed through the oxide, or the oil may be distilled to separate the light spirit, etc., from the heavier oil, each portion being then separately mixed with finely divided cupric oxide, agitated, and heated in a still. The distillate is free from sulphur and the cuprous sulphide may be re-oxidised to copper oxide. In the Frasch process (see this J., 1912, 169) a mixture of 75 parts of copper oxide, 10 parts of lead oxide, and 15 parts of iron oxide is used. Robinson (U.S. Pat. 910,581; this J., 1909, 198) states that sulphur compounds can be eliminated by using 98% sulphuric acid. Blackmore (Fr. Pat. 340,275 of 1901; this J., 1905, 127) treats the oil with calcium carbide, whilst in the Edeleanu process (Eng. Pat. 11,140 of 1908; this J., 1908, 974) liquid sulphur dioxide is used. On mixing the latter with a petroleum distillate, at about 5°C., two liquid layers are formed, the bulk of the

sulphur compounds being found in the lower layer. The author does not consider the Edeleanu method suitable for shale oils, particularly Kimmeridge shale oil, and is doubtful as to its suitability for heavy oils. The author, in conjunction with Lucas and Palmer, proposes to treat oil at high temperatures with gaseous ammonia, the temperature being sufficiently high to cause the ammonia to commence to dissociate. Oils treated in this manner are found to give off hydrogen sulphide. It is unfortunate that the sulphur in the very extensive beds of so-called Kimmeridge shale is present in such a form that a very high percentage passes into the oil on distillation, the amount varying from 5 to even 8%. The sulphur in this shale is found in all the fractions and in spite of the evolution of hydrogen sulphide the amount in the distillate is not much less than in the crude oil. Hall (Eng. Pat. 26,756 of 1913; this J., 1915, 167) proposes to remove sulphur from this shale by passing in sulphur dioxide gas and then distilling. Kimmeridge shale oil would be of immense value if this sulphur could be removed, owing to the high yield of oil per ton of shale. The oil retains water in a remarkable degree, one ton of shale giving 64.75 gallons of a crude oil containing 30.25 gallons of water and 3.74% of sulphur. The dry oil would probably contain over 7% of sulphur. In retorting shales sulphur might be eliminated by: (a) removal in the process of retorting, (b) passing the oil vapours before condensation through a desulphurising agent, (c) desulphurising the oil by chemical means. Obviously the first method is preferable. There is no objection to adding some material such as lime, and by previous treatment a larger yield of ammonium sulphate might follow. In the second case there is a danger of carbonisation, carbon being deposited upon the desulphurising material, stopping its action. The third method presents considerable difficulty, owing to the risk of loss by action of the purifying agents on the oil itself.—J. E. C.

Liquid fuel and its combustion. J. S. S. Brame. J. Inst. Petrol. Tech., 1917, 3, 194—216.

THE liability to interference with supplies of sea-borne petroleum oils and the attendant wide fluctuation in prices must tell against the wider introduction of such oil as fuel in this country. Suitable fuel oils may be obtained from Russia, Galicia, Roumania, Borneo, Burma, Persia, California, Texas, Mexico, and Trinidad. Fuel oil should possess a high calorific value, should be fluid at moderately low temperatures, free from solid matter, and of a satisfactorily high flash-point. According to the specification drawn up by the U.S. Bureau of Mines (Tech. Paper No. 3, 1911) the oil should have a closed flash-point of 140° F., it should not congeal at 0° C., it should not contain more than 2% water or 1% sulphur, and not more than traces of sand, clay, or dirt. The calorific value should not fall below 18,000 B.Th.U. per lb. The Admiralty specification does not include calorific value. Provision is made for testing the viscosity at freezing point. The flash-point should be over 175° F. close test, but for oils of low viscosity, such as shale oils, the flash-point should be over 200° F. Water should not exceed 0.5% and sulphur 3%. Acidity, calculated as oleic acid, should be below 0.05%. The author gives ultimate analyses of four typical oils, the following being an average: carbon, 84.7%, hydrogen, 11.5%, sulphur, 0.35%, oxygen and nitrogen, 3.49%. The average of the calorific values of thirteen varieties of fuel oils is 19,200 B.Th.U. (bomb calorimeter). Coal tar products are likely to play a far more important part as fuel oils in the future, as in normal times we shall produce far more tar than is required to furnish

the special by-products for which there is a market. In addition a large supply of fuel oil may be forthcoming from low-temperature carbonisation. Petroleum oils possess a superiority over tar or tar oils largely due to the higher oxygen content in the latter (13.6% as against 1.5%).

Among the earliest methods used for the combustion of oil fuel, were the open Nobel troughs and percolation over a porous bed of non-combustible material. Attempts were next made to gasify the oil, but difficulties arose owing to the choking of the vaporisers by carbon deposits, and attempts were then made to burn the oil in the form of a fine spray. It cannot be too strongly emphasised that no particular type of atomiser possesses superlative superiority, success depending mainly on the general design of the whole oil-burning system. Atomisation may be carried out by spraying with steam or air and by direct mechanical breaking up of an oil stream escaping under pressure. Full details, and illustrations of the principles of various modifications of each type are given. Usually steam atomisers do not respond so well as air or pressure systems, when boilers have to be forced. Air may be truly termed the natural atomising agent, because in addition to its spraying effect, it ensures each oil-globule being carried forward with the requisite air for combustion. Atomisation by air at low pressure is more economical than when higher pressures are used. Atomisers giving a long narrow cone of flame are more suited to the Lancashire type of boiler, the wider cone of flame from a pressure spraying burner being more suitable for the wider combustion space of the water-tube type of boiler. It is an advantage to heat the oil to assist the proper atomisation by reducing the viscosity, this point being essential with pressure sprayers. Philip (Eng. Pat. 14,778 of 1913; this J., 1914, 824) has found that the addition of 8% of naphthalene greatly reduces the viscosity of thick oils. The essential conditions for satisfactory combustion of oil are sufficiency of oxygen, proper admixture, and avoidance of contact of the flame with any cool surface before this stage is reached. The use of a heated air supply is beneficial with oil. Steam has a disadvantage owing to the considerable amount of heat carried away in the hot flue gases by reason of its high specific heat. In burning oil fuel ample combustion space is necessary. The author gives details and illustrations showing furnace arrangements in the Scotch marine-type boilers and in water-tube boilers. Proper baffling between the rows of tubes is advocated. The advantages of firebrick arches are discussed. Flames are low in radiating power, whilst highly heated firebrick provides a splendid radiating surface and catalytically promotes combustion. The author looks forward to oil attaining increased importance in the future, especially in internal combustion engines, but most marine engineers have every confidence in the future of the oil-fired boiler and steam turbine, and in locomotive practice oil fuel has proved its value probably more than in any other commercial application.—J. E. C.

PATENTS.

Pulverised fuel burners. L. H. Bergman, Philadelphia, U.S.A. Eng. Pats. (A) 106,248 and (B) 106,249, Jan. 18, 1917. (Appl. Nos. 933 and 942 of 1917.)

MEANS for the propulsion and combustion of

powdered fuel, utilising only one source of air supply, are claimed. The burner consists of concentric inner and outer pipes. In (A) the fuel is admitted to the inner pipe and is conveyed by a portion of the air from a common box, the air for combustion passing down the annular space between the pipes. In (B) the fuel is carried down the outer annular space, the air for combustion passing through the inner pipe.—J. E. C.

Coking-oven. M. Marshall, sen., Vancouver, B.C. U.S. Pat. 1,227,060, May 22, 1917. Date of appl., Dec. 13, 1916.

THE floor of a coke-oven of the beehive type is formed of perforated bricks and has a space below filled with permeable material and connected with a flue, so that the volatile matter given off during the coking may pass to suitable condensers.—W. H. C.

Coke-oven. E. J. Crossen, Joliet, Ill. U.S. Pat. 1,227,518, May 22, 1917. Date of appl., Sept. 25, 1915.

A LONG, narrow coke-oven having vertical flues, is provided with a regenerator chamber situated immediately beneath and divided by transverse partitions into a number of sections, each of which has a separate air connection. Gas is supplied to the combustion chambers of all the vertical flues of a battery of the ovens and means are provided to regulate the supply of air to the regenerators and from the latter to the combustion chambers.—W. H. C.

Gases under pressure; Storing of —. Acetylene Illuminating Co., Ltd., and R. J. McL. Whibley, London. Eng. Pat. 106,378, Aug. 21, 1916, (Appl. No. 11,868 of 1916.)

THE receptacle in which the gas is to be stored is provided with a fibrous lining and is filled with large pieces of porous material, and the interstices between the large pieces are filled with smaller pieces of suitable material which may be porous or not.—W. H. C.

Gases under pressure; Storing of —. Acetylene Illuminating Co., Ltd., and A. Stephenson, London. Eng. Pat. 106,406, Sept. 26, 1916, (Appl. No. 13,676 of 1916.)

THE receptacle containing the solvent or absorbent material is subjected to a low temperature and the gas is then admitted at such a pressure that it will liquefy at the temperature obtaining in the receptacle. Alternatively the gas may be liquefied before it is allowed to enter the receptacle and the cold produced by the evaporation of the liquefied gas used to cool the receptacle and the solvent or absorbent material. A separator is provided through which the gas passes on its way to the receptacle to remove impurities.—W. H. C.

Gasolene and other light oils; Method of obtaining — from heavier hydrocarbons. U.S. Jenkins, Chicago, Ill., Assignor to Jenkins Petroleum Process Co., Milwaukee, Wis. U.S. Pat. 1,226,526, May 15, 1917. Date of appl., July 13, 1916.

HEAVY hydrocarbons are heated in a still under pressure, and "the vapours of greater average density than that of the lowest produced in the still" are withdrawn at different points below the top of the chamber, condensed, and replaced by forcing fresh heavy hydrocarbon into the still.—J. E. C.

Oils; Process for refining —. W. M. Parker, Oklahoma, Assignor to Parker Process Co. U.S. Pat. 1,226,990, May 22, 1917. Date of appl., Apr. 4, 1916.

OIL is forced under relatively high pressure through

a coil heated to about 400° F. (205° C.) and mixed with a small proportion of high-pressure steam. The mixture is heated to about 1000° F. (about 540° C.) and vaporised, and simultaneously forced at high pressure through a long cylinder containing a coaxial helix, at a velocity not less than 100 feet per sec. The vapour is cooled to about 350° F. (177° C.) and the condensed liquid separated.—W. F. F.

Oil; Distillation of —. Apparatus for oil distillation. Revolvable retort for distilling oil. S. M. Herber, Inza, Mo. U.S. Pats. (A) 1,227,558, (B) 1,227,559, and (C) 1,227,560, May 22, 1917. Dates of appl., Aug. 7, 1915, Apr. 5, 1916, and Sept. 26, 1916.

(A) A HORIZONTAL cylinder, revolvable in either direction and supported by hollow trunnions mounted in bearings in a casing, is heated externally and oil and steam are fed to it by a perforated pipe passing through the retort and mounted within the trunnions. A perforated trough is supported by the feed pipe within the retort so that it receives the heavier residue. The distillate passes out at each end by the hollow trunnions to separating chambers from which the gaseous products are withdrawn, and the liquid residue is returned to the retort. (B) In a retort as in (A), condensers are connected to the separating chambers and the latter are resiliently supported on the trunnions to diminish vibration. (C) The retort is provided with external concentric rings having internal flanges which are attached to the retort, and external flanges which are provided with means for sealing the joint with the casing. Projecting ribs, also carried by the ring, rest in grooved wheels for supporting the retort, and one of the rings carries a sprocket wheel whereby the retort is driven.—W. F. F.

Apparatus for purification of gases. Ger. Pat. 296,209. See I.

Apparatus for detecting the presence of combustible gases. Eng. Pat. 106,427. See XXIII.

HB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Peat and other materials; Apparatus for carbonising — and obtaining distillates therefrom. C. Whitfield, Kettering. Eng. Pat. 106,121, May 6, 1916. (Appl. No. 6534 of 1916.)

PEAT or other material is fed from a hopper on to a series of revolving trays in a vertical carbonising chamber and is heated by gaseous products of combustion. Steam and vapours evolved are condensed in an apparatus in which the liquid products, after passing through an independent cooling coil, are re-introduced and act as cooling agents.—J. E. C.

Destructive distillation of carbonaceous materials. S. Glover, St. Helens, J. West, Southport, and J. Hargreaves, Widnes. Eng. Pat. 106,189, July 27, 1916. (Appl. No. 10,630 of 1916.)

A RETORT for the destructive distillation of carbonaceous materials is provided with a series of concentric gas collectors, tapering towards their lower edges, and extending into the relatively cool central area of the retort. A single distributing cone is also provided to direct the incoming material towards the internal periphery of the retort, the larger lumps rolling down to the region of the concentric gas collectors.—J. E. C.

[Wood] charcoal; *Process of making — and apparatus therefor.* S. Iwamoto, Osaka, Japan. U.S. Pat. 1,227,148, May 22, 1917. Date of appl., Aug. 28, 1915.

Wood is distilled in a closed retort, which is heated by a furnace connected with heating flues in the walls of the retort, and the distillation products are drawn off and recovered. The heating gases and air are then admitted into the retort so that the charcoal is further heated by partial combustion, thus rendering it more dense. The charcoal is removed while at a high temperature and rapidly cooled.—W. F. F.

X-ray tube. W. Robinson, West Lynn, Mass. U.S. Pat. 1,226,383, May 15, 1917. Date of appl., July 18, 1916.

AN X-ray tube has glass pockets formed in the walls of the tube, with mercury electrodes sealed in the pockets, one in the end and the other in the side of the tube, and a window at the other end permeable to X-rays.—J. E. C.

III.—TAR AND TAR PRODUCTS.

Benzene and toluene; Proposed manufacture of — in Australia. Board of Trade J., June 28, 1917.

THE Defence Department of the Australian Government proposes to erect plant for the production of benzene and toluene in the Commonwealth. The crude benzol will be obtained from the various Australian gas companies.

Catechol, quinol, and resorcinol; Biochemical reactions for differentiating —. J. Wolff. Ann. Chim. Analyt., 1917, 22, 105—107.

THE reaction of certain diphenols with laccase in presence of hydriodic acid and starch (this J., 1915, 738) may be utilised for the purpose of identifying the three isomeric diphenols, the result of the test being different according to whether it is carried out in presence of acetic or a mineral acid. The reagents required are a solution of 2% soluble starch and 3% potassium iodide; a glycerol infusion of *Russula delica* or other fungus rich in laccase; N/1 acetic acid and N/1 sulphuric acid. The fresh fungus is chopped into pieces the size of a nutmeg and steeped in about an equal volume of glycerol; the extract is filtered through glass wool for each series of tests. The solutions of the diphenols contain 1 grm. per litre. In the case of catechol, 2 c.c. of the solution is treated in a test-tube with 2 drops of the fungus extract, 5 drops of the starch-iodide solution, and 3 drops of acetic acid. An intense blue colour is rapidly developed. Under similar conditions a solution of quinol shows no reaction but if the acetic acid be replaced by sulphuric acid the blue colour gradually appears. With resorcinol no coloration is developed with either acid.—J. F. B.

Determination of naphthalene [in coal gas] by picric acid. Knublauch. See 11A.

PATENTS.

Benzenemonosulphonic acid; Preparation of —. Comp. des Produits Chimiques d'Alais and de la Camargue, Salindres, France. Eng. Pat. 101,973, Oct. 23, 1916. (Appl. No. 15,067 of 1916.) Under Int. Conv., Oct. 21, 1915.

BENZEMONOSULPHONIC acid is prepared by passing benzene vapour into sulphuric acid of any concentration, preferably at 120°—130° C. Water is eliminated as steam, and benzenesulphonic acid crystallises on cooling. *Example.*

The vapour of benzene is passed for 27 hours through 100 parts of sulphuric acid of 62° B. (sp. gr. 1.753), at 120° C. and the excess of benzene is removed by a current of hot air; 130 parts of crystalline benzenemonosulphonic acid is obtained on cooling. A suitable plant consists of a boiler from which the vapour of benzene passes into a receiver containing sulphuric acid heated to 120° C. by a steam jacket. The benzene vapour and steam passing away are condensed and flow into a separator, where the water is removed. The upper layer of benzene passes through a drying chamber, containing quicklime or calcium chloride, etc., and thence returns to the boiler.—F. SP.

Benzenedisulphonic acid; Method of separating — from sulphuric acid and converting it into a salt. L. M. Dennis, Ithaca, N.Y. U.S. Pat. 1,227,252, May 22, 1917. Date of appl., July 14, 1916.

THE mixture of benzenedisulphonic and sulphuric acids is treated with an organic solvent, e.g., benzene, which dissolves the sulphonic acid but not the sulphuric acid, and the solution is treated with a suitable compound to form a salt of the sulphonic acid, which is relatively insoluble in the solvent employed.—J. F. B.

Benzols; Process and apparatus for extracting — from heavy oils. E. Barbet et Fils et Cie. Eng. Pat. 100,493, May 17, 1916. (Appl. No. 7051 of 1916.) Under Int. Conv., Sept. 5, 1913.

SEE Fr. Pat. 473,082 of 1913; this J., 1915, 485.

IV.—COLOURING MATTERS AND DYES.

Colour-lakes; The theory of —. I. O. Baudisch. Z. angew. Chem., 1917, 30, 133—135.

THE author discusses the lake-forming azo dye-stuffs in their relation to Werner's theory of mordants (this J., 1908, 439). According to this theory the colour-lakes belong to the class of metal-complex salts, and the lake-forming dye-stuffs are characterised by the presence of a salt-forming group and a group capable of forming a co-ordinative combination with the metal atom in such a position that an internal metal-complex salt can result. The *o*-hydroxyazo dye-stuffs are typical mordant dye-stuffs which conform to this rule. The introduction of certain substituent groups in these and in the nitrosoarylhydroxylamines and the position of these groups in the benzene or naphthalene ring has a powerful influence on the pigment-forming properties through the effect of the substituent radicals on the internal complex salt-forming group. It has been shown that side chains which are able to bring spare valencies into play possess a particularly strong influence on this group. Instances are quoted where colour changes are determined by the spare valencies available in the dimethyl-amino, the toluenesulphonyl, and the aldehyde groups influencing internal copper-complex salt-forming groups. Further, the influence of the side chains is considerably stronger in a position *ortho* to the azo nitrogen than in the *meta* and *para* positions. The influence of the sulphonic group in the *ortho* position is illustrated in the case of the important lake-forming dye-stuffs Lake Red P and Lithol Red as compared with the corresponding isomeric *m*- and *p*-dye-stuffs. Pigment Scarlet 3 B is a lake-forming dye-stuff with a COOH group in the *ortho*-position; this exerts an influence on the complex-forming residue in virtue of spare valencies equivalent to those of an aldehyde group. A methyl group in the *ortho*-position to the nitrogen is antagonistic to lake formation, whereas a sulphonic group

attached to an *ortho* side chain is strongly favourable. Examples of a similar kind are found in the azo dyestuffs coupled with pyrazolone derivatives. In the anthraquinone series Werner's theory is consistent with the observation that the most valuable lake-forming dyestuffs are those containing *m*- and *o*-hydroxyls in positions contiguous to each other.—J. F. B.

Chromophors with auxochromic functions. II. Kauffmann. Ber., 1917, 50, 515—529.

FROM the facts that the nitro-derivatives of stilbene are coloured, whereas those of benzonitrile are colourless, and that stilbene itself possesses a violet fluorescence, it has previously been concluded (Kauffmann, "Die Valenzlehre," 1911, p. 496) that the styryl radical confers auxochromic properties. The influence of styryl on the fluorescence has been further investigated, and it has been found to be a typical auxochrome displacing the ultraviolet fluorescence of benzene into the visible spectrum. *p*-Distyrylbenzene (m.pt. 258° C.) has been prepared from terephthalic aldehyde and magnesium benzyl chloride; it is a coloured hydrocarbon with very powerful fluorescent properties, as distinct from *p*-dicyanobenzene. The luminophor is the central ring of the compound, as on gradual replacement of the two styryl groups by true auxochromes the fluorescence remains; thus replacement of one stilbene group gives *p*-dimethylaminostilbene, a substance possessing a very high fluorescence. In addition to its auxochromic character, styryl is also a chromophor, as shown by the introduction of true auxochromes, e.g., 2,4-diaminostilbene is light yellow. The more powerful the auxochromic properties of the styryl, the weaker are its chromophoric functions developed; thus *p*-dimethylaminostilbene is white and 1,3-distyryl 2,4-diaminobenzene (containing the styryl chromophor twice) is only light yellow. The entrance of a cyano-group increases considerably the chromophoric function of styryl, e.g., *p*-dimethylamino- α -phenylcinnamic nitrile is lemon yellow.—F. W. A.

Dyeing materials in the Philippines. J. Roy. Soc. Arts, 1917, 65, 553—554.

PROBABLY more than one hundred species of plants containing valuable colour principles are found in the Philippines, and many more could be readily cultivated. As these plants grow wild and often are widely scattered, the supply is unreliable and insufficient. Little has been done towards developing the manufacture of local colouring materials, and until there is an intensive cultivation of the necessary plants, and the capital necessary for the enterprise can be secured, there is little prospect of commercial success.

Only two Philippine dye plants are commercially important. These are indigo and sappan or sibucao. Others are used locally, but scarcely enter into domestic commerce.

Indigo (*Indigofera tinctoria*, Linn., and *I. suffruticosa*, Mill.) has been in the past extensively cultivated in some parts of the Philippines, and the prepared product entered extensively into the export trade. The cultivation of indigo as a commercial crop in the islands has now, however, practically ceased. Indigo is still cultivated on a small scale in some parts of Northern Luzon, but only to supply a limited local demand.

Sappan or sibucao (*Casalpinia sappan*, Linn.) is widely distributed in the settled areas of the Philippines at low and medium altitudes. It is not systematically cultivated, yet in a few districts it is found in great abundance. Exports of sappan wood from the Philippines to China (exclusive of Hong-Kong) in 1914 amounted to 1,515,756 lb., valued at £1343, and to Hong-Kong

amounted to 621,597 lb., valued at £586. No exports to other countries are on record. This wood yields about 2% of red colouring material by extraction with water. The wood contains brazilin, the colouring matter found in brazil-wood.

Brown dyes are obtained from numerous plants, chiefly from the shrub or small tree known as bancado or nino (*Morinda indica*, Linn.), certain mangrove trees, such as ceriops and bruguiera and the bark of *Nylocarpus* (tabigue or nigui). Many of these barks are useful in tanning as well as dyeing. Bancado is the well-known *al* dye of India. It dyes dark red shades on cotton mordanted with tannin. Black dyes are secured from *Heritiera litoralis*, Dry. (dongon late), a common coastal tree, and from some species of *Hibiscus*, *Semecarpus*, *Terminalia*, and *Diospyros*. Yellow dyes of minor importance are secured from the seeds of *Bixa orellana*, Linn. (achuete); from the wood of *Neuclea* (baucal); from *Carthamus tinctorius*, Linn., which is occasionally cultivated as a dye plant; from the bark of the common mango; from some species of *Vitex* (molave); and from ligtang, a woody vine having yellow wood rich in berberine. Berberine is found in several plants of the Philippine Islands. Turmeric (*Curcuma longa*, Lam.) does not occur in sufficient quantities in the Philippines to yield a useful supply of the rhizomes. The herbaceous plant, *Peristrophe tinctoria*, Nees, is widely scattered in the settled areas in the Visayan Islands and is sometimes cultivated on a small scale. It yields a beautiful red dye, which is locally used in the Philippines. It is doubtful whether the plant can be obtained in sufficient quantities or whether its commercial utilisation is possible.

PATENT.

Chromium compounds of the gallocyanine series and a process of making same. G. Engi, A. Grob, and J. Würzler, Assignors to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,227,407, May 22, 1917. Date of appl., Nov. 27, 1915.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wool; The elasticum reaction of—. K. Naumann. Z. angew. Chem., 1917, 30, 135—137.

THE "elasticum" reaction described by Von Allwörden (this J., 1916, 416) for the detection of damaged wool, based on the change of microscopic structure on treatment with chlorine water, has been submitted to a thorough investigation. It is still too early to attach a practical significance to the results of this test because they vary with different kinds of wool, but with certain limitations it may be said that they are more or less the same for the same kind of wool. It is, however, most important to extend the examination over the entire length of the fibre, the reaction being different in different parts of the same fibre. A typical wool fibre, when treated with chlorine water under the prescribed conditions, will show no elasticum globules at the end furthest from the skin for a distance of 4—5 mm.; beyond this point a few isolated globules are found, increasing in closeness until they form a continuous chain. The swellings are most regularly continuous about the middle of the fibre and decrease in regularity and continuity towards the basal, clipped end of the fibre, without, however, ceasing altogether as at the point end. All varieties of wool show the reaction but in different degrees. The largest divergence from the typical reaction was shown

by a very coarse Australian cross-bred wool; this showed no swellings from the point to the middle of the fibre and thence only occasional globules to the base; total length 114 mm. Somewhat similar results were obtained with two samples of lamb's wool; no swellings were observed at the point and only a few near the base; at the middle occasional single globules alternated with short chains. A preliminary extraction with benzene in a Soxhlet apparatus makes the elasticum reaction much clearer and finer than with wool simply scoured with sodium carbonate. Dyeing operations in sodium sulphate-sulphuric acid or acetic acid baths and after-treatment with chromic acid do not affect the elasticum reaction, but dyeing in neutral sodium sulphate baths causes it to disappear. The action of caustic soda with increasing temperature has a greater effect on the elasticum reaction than with increasing concentration, and treatment with caustic soda at 50° C. under similar conditions to indigo vat dyeing does not destroy the reaction. The addition of formaldehyde moderates the action of caustic soda so that wool may be treated with the alkali in presence of formaldehyde without destruction of the elasticum under conditions which remove it entirely in the ordinary way. In the case of yarn a shrinkage of about 3% was observed without formaldehyde and no shrinkage when formaldehyde was present. Both samples of wool behaved equally well in fulling and it would appear that the elasticum reaction does not afford an indication of the fulling quality of the wool.—J. F. B.

Sulphuric acid on cotton; Action of —. H. Wilkinson. J. Soc. Dyers and Col., 1917, 33, 148—151.

DETERMINATION of the strength of unbleached cotton yarn after treatment with sulphuric acid and drying in air indicated that the tendering action increased the longer the acid remained on the fibre, and that on washing in water or alkali the cotton regained in strength an amount approximately equal to the strength in the acidified condition. Cotton which had been subjected to the acid treatment behaved like ordinary cotton on mercerising, gaining further in strength. —F. W. A.

Bleaching of cellulose; Determination of the degree of — by means of the copper value. M. Freiberger. Z. angew. Chem., 1917, 30, 121—122. (See also Schwalbe, this J., 1915, 23.)

To obtain trustworthy results in the determination of Schwalbe's copper value for cellulose certain precautions are essential. The alkaline tartrate solution should be freshly prepared, since traces of sodium silicate dissolved from the glass will materially increase the copper value. For preparing the solution pure sodium hydroxide made from metallic sodium should be used. It is dissolved in a polished iron vessel, which has previously been freed from fat by treatment with alcohol and ether, and the potassium sodium tartrate is added to the cold solution. Old copper sulphate solutions give too high results, and this solution should also be freshly prepared. To avoid solution of silica the distilled water should be kept in a stoneware instead of a glass vessel, and rubber stoppers, which yield particles to the liquid, should not be used. The method of boiling the Fehling's solution in Gnehm's apparatus has an influence on the results. The sides of the flask should be protected against over-heating, by means of an asbestos screen, and the liquid should always show numerous steam bubbles. After removal of the burner the supernatant liquid is at once poured into a beaker, and the fibres in the flask are rapidly washed several times by decantation with water at about 80° C., and allowed to stand covered

with warm water while the Fehling's solution and washings are being filtered. In this way the further deposition of copper which takes place when dilute Fehling's solution is heated is prevented. Finally the fibre residue is repeatedly washed and removed from the flask. Filtration through paper (No. 595 Schleicher and Schüll) gives more uniform results than filtration through asbestos in a Gooch crucible. The copper is dissolved in nitric acid, and the solution allowed to stand for 1 to 2 days, and filtered shortly before electrolysis. A blank determination should also be made, and the amount of copper obtained should be deducted from the copper value, but only a slight quantity of copper should separate in the blank test.—C. A. Textile fabrics used in aircraft. J. Turner, Preston, and I. Turner, Blackburn. Eng. Pat. 106,113, Nov. 13, 1916. (Appl. No. 5270 of 1916.)

TEXTILE fabrics to be used in aircraft are strengthened to resist ripping by strands of gut or gut-substitute (imitation gut formed from plaited silk) introduced therein at suitable intervals (2—6 ins.) both in the warp and the weft during weaving.—J. F. B.

Viscose; Process of producing glossy threads from —. M. Biroli. Pavia, Italy. U.S. Pat. 1,226,178, May 15, 1917. Date of appl. Nov. 18, 1916.

GLOSSY threads are produced by passing viscose threads into a bath of sodium bisulphate to form the xanthogenate, and then into a bath containing an organic acid, with or without the addition of suitable salts, to fix the threads.—F. Se.

Acetylcellulose; Solvent for —. W. G. Lindsay, Caldwell, N.J., Assignor to The Celluloid Co., New York. U.S. Pats. (A) 1,226,339 and (B) 1,226,340, May 15, 1917. Date of appl., May 23, 1912.

(A) A MIXTURE of 54—61 parts by weight of benzene and 46—39 parts of methyl alcohol, the latter containing 3.5—7% of water, is a solvent for acetone-soluble acetylcellulose. (B) A mixture of epichlorhydrin and methyl (or ethyl) alcohol in about equal proportions is a solvent for acetone-soluble acetylcellulose, and the combination of these with *p*-ethyltoluenesulphonamide, with or without triphenyl phosphate, and acetone-soluble acetylcellulose, is claimed.—F. Se.

Acetylcellulose plastic compounds; Process of making —. W. G. Lindsay, Caldwell, N.J., Assignor to The Celluloid Co., New York. U.S. Pats. (A) 1,226,341, (B) 1,226,342, and (C) 1,226,343, May 15, 1917. Date of appl., July 10, 1915.

(A) A PLASTIC material is produced from acetone-soluble acetylcellulose by gelatinising it at ordinary temperatures with a mixture of water, benzene, and methyl alcohol, adding *p*-ethyltoluenesulphonamide and manipulating the mass in the usual manner. (B) Acetone-soluble acetylcellulose is mixed with *p*-ethyltoluenesulphonamide, with or without the addition of triphenyl phosphate, and gelatinised by a mixture of methyl acetate and methyl alcohol. (C) Acetone-soluble acetylcellulose is mixed with *p*-ethyltoluenesulphon-

amide, with or without the addition of triphenyl phosphate, and gelatinised by a mixture of epichlorhydrin and ethyl or methyl alcohol.

—F. Sp.

Duplicating paper ["carbon paper"]; *Manufacture of* —. H. Wade, London. From B. B. Goldsmith, New York. Eng. Pat. 106,167, June 7, 1916. (Appl. No. 8081 of 1916.)

THE sheet is first impregnated or coated on one or both sides with any waxy or greasy material, and a pigment composition containing a fat, oil, or waxy substance is applied to the foundation sheet of waxed paper on one or both sides.

—J. F. B.

Pulp, paper, cardboard and the like; Arrangements for heating and draining the cylinders of machines for making and treating —. W. A. Aitken, Gravesend. Eng. Pat. 106,228, Nov. 3, 1916. (Appl. No. 15,721 of 1916.)

THE drying cylinders of a paper machine are divided into two or more groups and the whole of the steam required for drying is admitted at the dry end and caused to flow towards the wet end of the series. Each group of cylinders has a separate main supply pipe and a separate main discharge pipe, and the outlet main of each group is connected with the inlet main of the next group. The inlet main of the latter group is placed at a higher level than the outlet main of the previous group which feeds it, and the latter is provided with a drainage pocket at its closed end. The outlet main of the last group of cylinders discharges into a hot water tank and the drainage pockets of the previous groups also discharge into the pipe leading to the water tank in such a manner that the drainage water acts as an ejector for the water passing from the last outlet main.

—J. F. B.

Ink-removing and bleaching compound [for treating paper-stock]. I. J. Wright, Kalamazoo, Mich. U.S. Pat. 1,226,735, May 22, 1917. Date of appl., June 29, 1916.

A composition for removing ink from paper stock is prepared with 4 lb. of sodium carbonate, $\frac{3}{4}$ lb. of bleaching powder, 1 gall. of kerosene, and 6 lb. of soap, combined with water.—J. F. B.

Acids or metallic salts [from vulcanised fibre]; *Process of eliminating and recovering* —. H. E. Tiffany, Assignor to The Continental Fibre Co., Newark, Del. U.S. Pat. 1,226,279, May 15, 1917. Date of appl., Jan. 5, 1916.

THE acids or metallic salts employed in the hardening of fibre are recovered by placing the fibre saturated with the hardening material in a bath containing an electrolyte and subjecting it to electrolytic action in order to remove and recover the acid or metallic salt, employing the saturated fibre as one of the electrodes.—J. F. B.

Pulp; Process of separating suspended —. W. Hoskins, Chicago, Ill. U.S. Pat. 1,226,333, May 15, 1917. Date of appl., Oct. 15, 1915.

PAPER pulp is separated from a liquid containing a chemically active substance, e.g., an acid, by passing the liquid over an immersed solid, e.g., a carbonate, which is acted upon by the chemical substance in the pulp liquid to evolve gaseous products. The liberated gases, rising through the liquid, carry with them the suspended particles of pulp to form a scum on the surface which is then removed. Suspended pulp is recovered from the waste waters of sulphate pulp digestion by passing the waters over immersed limestone and removing the pulp-carrying surface-stratum.—J. F. B.

Fertiliser [from sulphite-cellulose waste liquor] and *process of making same*. U.S. Pat. 1,225,825. See XVI.

Process for moulding compressed gunpowder and similar materials. Ger. Pat. 296,245. See XXII.

[Cellulose ester] *composition for waterproofing the striking or abrasive surfaces of match boxes and the like*. Eng. Pat. 156,375. See XXII.

VI.—BLEACHING ; DYEING ; PRINTING ; FINISHING.

Electrolytic bleaching liquors; "Twaddelling" of —. G. G. Hepburn. J. Soc. Dyers and Col., 1917, 33, 135—137.

THE utility of estimating the strength of bleaching powder solution and especially electrolytic bleach liquors by a method based on the use of a hydrometer is emphasised. A method is outlined for correlating a burette reading obtained on titrating with thiosulphate with degrees Twaddell (of good quality bleaching powder solutions), and the term "chlorimetric-degree Twaddell ($^{\circ}$ Tw. Cl)" is suggested for the value 2.70 grms. of available chlorine per litre ($=1^{\circ}$ Tw. bleaching powder solution).—F. W. A.

Sodium sulphide in sulphide dye baths; Estimation of —. H. Swann. J. Soc. Dyers and Col., 1917, 33, 146—148.

THE sodium sulphide solution is distilled with ammonium chloride solution containing 5% of ammonia and the ammonium sulphide collected in an excess of standard iodine acidified with acetic acid, the excess being determined by means of standard thiosulphate or arsenite.—F. W. A.

Cotton; Tendering of — in dyeing half-woollen goods in baths of weak acids. W. Zünker and O. Mann. *Färber-Zeit.*, 1916, 27, 355. *Chem.-Zeit.*, 1917, 41, Rep., 161.

CASES of tendering of cotton have been observed in half-woollen piece goods dyed in baths containing acetic acid and Glauber's salt. In studying the causes of such damage account must also be taken of the possible effect of hot pressing, calendering, and finishing of the goods. Even small quantities of acetic acid cannot be washed out from cotton with pure water so that no reaction to litmus remains. Complete elimination can be obtained by leading strongly superheated steam at about 200° C. over the moist cotton for about an hour, which can be done without damage provided no air be present. Tensile tests on cotton boiled with water, acetic acid, and formic acid under the conditions of half-wool dyeing and then submitted to the usual finishing operations showed a loss of strength of 40—45% for acetic acid and 50—55% for formic acid as compared with water. With the addition of Glauber's salt, owing to the resulting decrease of hydrogen ion concentration, the loss of strength with acetic acid was reduced to 20—25% and with formic acid to 25—30%. With the presence of wool in the bath, intimately mixed with the cotton, the results were reversed, the loss of strength with acetic acid in presence of Glauber's salt being 50—55% and with formic acid 30—60%. In practice, the nature and type of weaving of half-woollen piece goods has a considerable influence, since narrow-ribbed goods have proved resistant, while broad-ribbed goods of the same material have been damaged under identical treatment; in the one

case the wool acts on one warp thread and in the other its action is divided between two. The finishing also affects the thick-ribbed material more strongly. The dyeing and finishing always have a more pronounced influence in the case of goods in which the cotton forms a smooth, extremely thin layer on the surface of the material, finished with a high gloss. Dyeing with acetic acid and Glauber's salt or with acetic acid alone is the best means available for treatment of half-woollen piece goods.—J. F. B.

Acid colours on cotton: Process for the fixation of —, F. W. Weeks. J. Soc. Dyers and Col., 1917, 33, 130—134. (See Eng. Pat. 102,291 of 1916; this J., 1917, 80.)

THE following printing colour for acid dyestuffs is recommended: To 50 grms. of acid dyestuff, 50 grms. of acetic acid, and 200 grms. of water are added 425 grms. of thickening, 350 grms. of aniline salt solution (4:10), and 125 grms. of hexamethylenetetramine solution (equal vols. of 20% ammonia and 40% formaldehyde). The amount of aniline salt must be determined for each dyestuff. Easily reduced dyestuffs are not suited to the process, reduction taking place slowly in the printing colour. Difficulties were met with in endeavouring to dye goods on the jigger, but the padding process has been found to be of considerable value. The fastness to light of dyeings produced from acid colours in this manner appears to approximate to the fastness of the same dyestuffs on wool. The process may be used in combination with ordinary chrome printing colours.—F. W. A.

PATENTS.

Textile fabrics: Process of rendering — "antique," M. B. Adom, White Plains, N.Y. U.S. Pat. 1,227,361, May 22, 1917. Date of appl., June 28, 1915.

THE fabric is treated in a warm bath containing the reaction products of sodium hydroxide, sodium bisulphite, and sodium peroxide, until the colours of the fabric have been subdued to the desired point; it is then washed in "chlorinated water" to clear the whites, then with hot water and a potassium soap, and finally treated in an acid bath containing Acid Violet or other blueing agent.

—J. F. B.

Fast tints on animal fibres: Process for producing —, G. Engi, A. Grob, and F. Straub, Assignors to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,227,406, May 22, 1917. Date of appl., Nov. 27, 1915.

SEE Eng. Pat. 15,456 of 1915; this J., 1916, 1255.

Production of white silica [for finishing textiles]. Eng. Pat. 106,232. See VII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphur in pyrites: Volumetric determination of —, T. J. I. Craig. Chem. News, 1917, 115, 253—255, 265—268.

FIVE grms. of finely-ground pyrites is treated with a mixture of 50 c.c. of nitric acid (sp. gr. 1.42) and 50 c.c. of water; when all action has ceased, the solution is cooled to 50° C., 3 c.c. of bromine and 20 c.c. of nitric acid (sp. gr. 1.42) are added, the mixture is boiled, evaporated to dryness, the residue moistened with water, again evaporated, and then heated at 110° C. for 1 hour. The dry residue is now heated for 30 minutes with 50 c.c. of water, diluted to 100 c.c., filtered, and the insoluble portion washed until free from acid; the filtrate

and washings are made up to 250 c.c. Fifty c.c. of this solution is treated with a slight excess of *N/1* sodium hydroxide solution, the mixture is boiled, transferred to a 200 c.c. flask, diluted to 200.3 c.c. (allowance for volume of precipitate), and filtered; 100 c.c. of the filtrate is added to a quantity of water free from carbon dioxide and acidified with a definite quantity of *N/1* sulphuric acid and the solution is titrated, while boiling, with *N/1* sodium hydroxide solution, using phenolphthalein as indicator. The quantity of available sulphur in the pyrites is then calculated from the volume of alkali solution actually used, after allowing for the dilutions and the quantity of sulphuric acid added. The nitric acid used for dissolving the pyrites is expelled completely by the above treatment; when *aqua regia* is employed it may be necessary to remove the last traces of hydrochloric acid by means of moist silver oxide.

—W. P. S.

Saltpetre: its origin and extraction in India. C. M. Hutchinson. Bull. 68, Agric. Research Inst., Pusa. 24 pages.

THE extraction of potassium nitrate from soil can only succeed in countries where a large amount of nitrate can be extracted from a comparatively small amount of earth, and these conditions are allied with those which favour the nitrification of nitrogenous organic matter, and the accumulation of the resulting nitrate in the soil. The following appear to be the conditions which favour the production of nitrates in concentrated form:—1. *Nitrifiable organic matter*, in suitable proportion, in the soil. 2. *Lime*. 3. *Water*; not only in sufficient amount for nitrification, but also distributed in the soil in such a way as not to interfere with aeration, and to provide for continual capillary rise to the surface. 4. *Soil*, of such a texture as to allow of continuous upward movement of water from the subsoil to the surface. 5. *Climate* ensuring a provision of adequate moisture and temperature during part of the year, and complete or nearly complete absence of rainfall, coupled with low humidity, during a sufficiently long period to ensure the capillary rise of subsoil water, consequent on rapid surface evaporation. The saltpetre at present extracted in India is obtained principally in the immediate neighbourhood of human habitations, where accumulation of organic refuse and excreta has occurred—and practically the whole supply of the nitrate earth, "chihua," is derived from village-sites, either old or new. No special bacterial action is needed to explain the accumulations which occur, nor do the nitrifying bacteria which are found associated with these earths possess any abnormal nitrifying powers. The process of extraction is fully described and is illustrated by photographs and diagrams. The general conclusions arrived at from study of the facts are:—(1) The present sources of saltpetre are not fully utilised, on account of the drawbacks at present associated with the industry, and the low price of crude saltpetre. 2. Artificial nitre-beds, on account of the favourable soil and climatic conditions in Bihar, would probably form a useful added source of saltpetre. 3. The present methods do not allow of recovery of all the nitrate present in the earth. Investigation is required to determine whether a better method of extraction could be devised, capable of being carried out by the present workers, and whether the efficiency of this method would necessarily depend upon some relaxation or revision of the restrictions at present imposed by the Salt Department. 4. The present conditions of trade in saltpetre require examination, to determine whether a greater demand for Indian saltpetre would result from organised efforts to improve these conditions, such as the elimination of the middle-man and the standardisation of the product.—J. B. C. K.

Kelp industry in British Columbia.

For several years the question of utilising the supply of raw material to be found in the kelp beds along the British Columbia coast, for the manufacture of potash and other products, has occupied the attention of Vancouver capitalists. A company was organised in 1915, and a plant established at Sydney, British Columbia, for the production of potash and algin. This company is now utilising from thirty to forty tons of raw kelp daily in the manufacture of a fertiliser. The product is a fine, dry, but heavy powder. Plans are being made to enlarge the plant and instal special machinery for the extraction of other materials from kelp. It is believed that the manufacture of iodine and potash, without the production of by-products, would not prove very profitable in normal times, but the increase in the price, especially of potash, on account of the war, will enable the British Columbia Company to include these and other by-products in the output of the factory at Sydney. The value of potash imported into Canada annually is about £200,000. It is estimated that the kelp beds on the coast of British Columbia contain sufficient material to manufacture potash, not only for the local market, but for export also. An Act relating to the licensing of kelp-reduction works, designed especially to encourage the development of the industry and for the protection of persons or companies desiring to engage in the business, was passed by the 1915 session of the Provincial Legislature. The industry is under the jurisdiction of the Minister of Fisheries. A licence protects the operation of any reduction factory for an area extending fifty miles along the coast.

Dissociation points [of calcium carbonate and hydroxide and gypsum]: Note on the determinations of —. E. T. Montgomery and M. M. Groves. *Trans. Amer. Ceram. Soc.*, 1916, 18, 214—222.

The material to be examined was heated in a platinum capsule in an electric furnace. The capsule was suspended by a short platinum wire and a longer steel one from the arm of a delicate balance placed directly above the furnace, the wire passing through a hole in the bottom of the balance case. The mouth of the furnace was closed by a fire-clay plug with two holes—one for the suspending wire just mentioned and the other for a thermocouple, the junction of which was placed just outside and near the bottom of the capsule. The holes in the clay cover were large enough to prevent any pressure developing in the furnace when gases were evolved from the materials under investigation. Calcium carbonate lost weight at the rate of 2.35% per hour at 620°–627° C., and at the rate of 4% per hour, gradually falling to less than 1% per hour, at 647° C., the whole of the carbon dioxide being expelled in 15 hrs. Calcium hydroxide lost about 1% of mechanically-held water at 400° C. and dissociated at 430°–439° C., any calcium carbonate present dissociating at 617° C. Gypsum ($\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$) lost all its water at 105°–107° C. No hemi-hydrate, such as is supposed to correspond to plaster of Paris, was produced and the authors question its existence. In the discussion, W. E. Emley suggested that the authors had overlooked the influence of the pressure of the gases in the capsule and also the time required to reach equilibrium. The latter is particularly shown by their failure to produce the hemi-hydrate at 80° C.—A. B. S.

Oxidation-reduction reactions [ferrous salts and potassium bichromate]: Conductivity measurements upon —. G. Edgar. *J. Amer. Chem. Soc.*, 1917, 39, 914–928.

MEASUREMENTS of the change of conductivity of

solutions of ferrous salts during oxidation by potassium bichromate, lead to the conclusion that the end point of the reaction may be determined in this way with a degree of accuracy equal to or greater than that of the usual volumetric method.

—W. H. P.

Metal oxides; Action of sulphur dioxide on —. D. L. Hammick. *Chem. Soc. Trans.*, 1917, 111, 379–389.

Two distinct types of reactions have been distinguished among the metals dealt with. Cuprie, bismuthic, and mercuric oxides, together with manganese peroxide, may be classed with lead peroxide, and, whilst the oxide in these cases may be reduced entirely or partially to a lower oxide or to metal, the sulphur dioxide is oxidised. At the same time, the original, or a lower, oxide may combine with the sulphur trioxide to form a normal salt such as CuSO_4 , MnSO_4 , etc., or a basic salt, such as $4\text{Bi}_2\text{O}_3 \cdot 3\text{SO}_3$. Stannous, lead (PbO), ferrous, and manganous oxides have given reactions similar to those of the alkaline-earthis. The production of sulphite has not been observed, but the formation of sulphide and sulphate, accompanied sometimes by the production of free sulphur and sulphur trioxide, indicates that the intermediate formation of sulphite has occurred. Whatever the first step may be, there is in these cases an indication of the reduction of sulphur dioxide.

—B. N.

Lead; Arsenates of —. C. C. McDonnell and C. M. Smith. *J. Amer. Chem. Soc.*, 1917, 39, 937–943. (See also this J., 1916, 1154 and 1258.)

THE basic arsenate of lead first prepared by Strömholm (this J., 1904, 252) has the formula $8\text{PbO} \cdot \text{As}_2\text{O}_5 \cdot \frac{1}{2}\text{H}_2\text{O}$, and can be prepared in a crystalline state by dissolving di-lead arsenate in 10% potassium hydroxide to saturation, and then pouring the filtered solution into about 5–8 times its volume of boiling water. A basic arsenate prepared by the action of ammonia on di-lead arsenate can also be obtained in crystalline form. Crystallographically it is similar to mimetite, and analytical data suggest the formula, $\text{Pb}_4(\text{PbOH})(\text{AsO}_4)_3 \cdot \frac{1}{2}\text{H}_2\text{O}$. A new basic arsenate has been prepared with the formula, $\text{Pb}_3(\text{PbOH})_2(\text{AsO}_4)_4$. The method of preparation is similar to that given for the first basic arsenate mentioned above, except that a large excess (20 or more vols) of water is used.

—W. H. P.

Basic salts of zirconium; Properties and constitution of some new —. E. H. Rodd. *Chem. Soc. Trans.*, 1917, 111, 396–407.

A BASIC zirconium sulphate may be prepared by partly neutralising an impure dilute solution of zirconium sulphate in sulphuric acid by means of ammonia. From this basic sulphate, a new basic chloride, $\text{Zr}_5\text{O}_8\text{Cl}_4 \cdot 22\text{H}_2\text{O}$, named 5:4 basic zirconium chloride, has been obtained, where $\text{Zr}:\text{Cl}=5:4$. It is a crystalline salt, very readily soluble in water, and can be recrystallised unchanged from a hydrochloric acid solution. Soluble sulphates precipitate from solutions of it an insoluble 5:2 basic sulphate, $\text{Zr}_5\text{O}_8(\text{SO}_4)_2 \cdot x\text{H}_2\text{O}$, where x is probably 14. By the action of ammonia on either the 5:4 chloride or the 5:2 sulphate, a hydroxide is obtained which is distinct from the normal hydroxide, as in hydrochloric acid it is again dissolved, forming the 5:4 basic chloride. By adding sulphuric acid to a boiled solution of zirconium oxychloride, $\text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$, a basic sulphate is obtained, identical in composition with the 5:2 basic sulphate, but quite distinct from it in properties. Constitutional formulae are suggested for the new and other basic zirconium salts. The formation of the many complex zirconium

salts is attributed to hydrolysis of the simpler salts, followed by condensation in dilute solution and at high temperatures, brought about by the weak basicity of zirconium hydroxide and its amphoteric character. The final product of these changes is metazirconic acid, which has probably a very complex molecule.—B. N.

Zirconia; Compounds of — with sulphuric acid. E. Chauvenet. *Comptes rend.*, 1917, 164, 864—865.

ZIRCONIA and sulphuric acid were mixed in various proportions, all water expelled by heating to 200° C., and the specific gravities of the resultant solids determined. The curve obtained from these data indicates the existence of the following compounds: $\text{Zr}(\text{SO}_4)_2$; $\text{ZrO}_2 \cdot \text{Zr}(\text{SO}_4)_2$; $7\text{ZrO}_2 \cdot 5\text{Zr}(\text{SO}_4)_2$; $5\text{ZrO}_2 \cdot 3\text{Zr}(\text{SO}_4)_2$; $2\text{ZrO}_2 \cdot \text{Zr}(\text{SO}_4)_2$ and $3\text{ZrO}_2 \cdot \text{Zr}(\text{SO}_4)_2$. No evidence was obtained of the existence of various other sulphates which have been described in the literature.—W. H. P.

Rare earth compounds; Study of some —. A. J. Grant and C. James. *J. Amer. Chem. Soc.*, 1917, 39, 933—937.

THE double oxalates of a number of rare earths and methylamine, ethylamine, or triethylamine have been prepared, but their solubilities do not appear to be sufficiently divergent to allow of advantageous fractional crystallisation. In the group of yttrium earths fractional precipitation of the ferrieyanides appears to afford the most rapid method of purification known.—W. H. P.

Nitrogen trichloride; Experiments with —. C. T. Dowell and W. C. Bray. *J. Amer. Chem. Soc.*, 1917, 39, 896—905.

NITROGEN trichloride is conveniently prepared by the action of hypochlorous acid on ammonium chloride solution in the presence of an inert solvent. The solvent preferred by the authors is carbon tetrachloride which does not react with the nitrogen trichloride or with chlorine. Solutions prepared in this way can be preserved in the dark for several weeks without serious contamination with chlorine. The decomposition of nitrogen chloride appears to be autocatalytic and to become more rapid in the presence of chlorine. The reaction of nitrogen trichloride solution with reducing agents leads usually to the formation of a certain amount of nitrogen as well as ammonia. The only reagent found which gives ammonia and chloride quantitatively is sodium sulphite and this is therefore used for the analysis of stock solutions. With arsenious acid nitrogen is evolved, the amount increasing rapidly with dilution, and also with the concentration of sulphuric acid present. Hydrogen sulphide solutions caused the evolution of nitrogen (about 5.5% of the whole) in quantity independent of the acid concentration. Potassium iodide in acid solution also yields nitrogen, the quantity being apparently independent of the concentration of iodide or of acid. Sodium hydroxide causes rapid decomposition with formation of a little ammonia and much nitrogen. Nitrogen trichloride reacts slowly with dilute ammonium chloride and more rapidly with a concentrated solution giving nitrogen and hydrochloric acid.—W. H. P.

Chlorine and ammonia; Reactions between —. W. C. Bray and C. T. Dowell. *J. Amer. Chem. Soc.*, 1917, 39, 905—913.

AFTER summarising the experimental data available the authors consider in particular the reaction of Noyes and Lyon (this J., 1901, 243) in which chlorine gas treated with slightly less than 2 mols. of ammonia in 0.5% solution gives equimolar quantities of ammonium and nitrogen chloride: $12\text{NH}_3 + 6\text{Cl}_2 = \text{N}_2 + \text{NCl}_3 + 9\text{NH}_4\text{Cl}$.

They conclude that this is probably not a true stoichiometrical reaction, and suggest that monochloramine, NH_2Cl , is probably the primary step in the formation of nitrogen by reaction of chlorine and ammonia in alkaline solution, and possibly also in the formation of nitrogen chloride in acid solution.—W. H. P.

Vapour pressures of various compounds at low temperatures. G. A. Burrell and I. W. Robertson. U.S. Bureau of Mines, Techn. Paper No. 142, 1916. 30 pages.

THE compounds studied were ethylene, isobutylene, propylene, ethane, propane, isobutane, sulphur dioxide, nitrous oxide, ammonia, and acetylene, at pressures from 1 to 760 mm. The substance was maintained at a constant temperature in a glass bulb immersed in gasoline from natural gas contained in a Dewar flask. The temperature could be maintained to within 0.04° C. by passing in liquid air from a larger Dewar flask in which the pressure could be adjusted by means of a water column. A special manometer was used for the measurements and temperatures were read on a pentane thermometer which was specially calibrated. The results are tabulated and equations for the vapour pressure curves were deduced with the aid of Nernst's formula. Approximate values for the heats of evaporation were also obtained from the Clausius-Clapeyron equation. The boiling points (760 mm.) obtained are: ethylene, -103.9° C.; ethane, -89.3° C.; acetylene, -84.0° C.; isobutane, -13.4° C.; ammonia, -34.6° C.; propane, -41.1° C.; propylene, -47.8° C.; butane, -0.3° C.; sulphur dioxide, -11.0° C.; and nitrous oxide, -88.7° C.—W. PATENTS.

Sulphuric anhydride; Process of making —. C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,227,044, May 22, 1917. Date of appl., June 13, 1916.

GASES containing sulphur dioxide and oxygen are brought into contact with tin chromate at a temperature at which this compound acts as a catalyst. The products of the reaction are passed through sulphuric acid in order to absorb the sulphuric anhydride produced, and the residual gases are then passed through a second mass of the tin chromate material. The catalyst should be free from fixed alkalis.—J. B. C. K.

Caustic soda; Process of making [purifying] —. H. B. Kipper, Solvay, N.Y., U.S. Pat. 1,227,453, May 22, 1917. Date of appl., Mar. 31, 1915.

SOLUTIONS of caustic soda containing from 50 to 60% Na_2O are subjected to electrolysis with a steel

cathode at temperatures from 80° to 175° C. Oxygen is liberated at the anode, and the metallic impurities are precipitated. The oxygen is collected and led away, to prevent any further action upon the body of the solution.—J. B. C. K.

Silica: Production of white—[for finishing paper, textiles, etc.]. R. G. Varcoe, Trentham, Staffs. Eng. Pat. 106,232, Nov. 22, 1916. (Appl. No. 16,728 of 1916.)

THE quartz which is left as a residue after the extraction of china-clay from clay-stone, is screened to remove sand and other foreign matter, and is then ground, washed, and dried. The resulting powder is white and contains a certain proportion of alumina in addition to the silica. The proportion of alumina can be increased, if desired, by adding the required amount of china-clay to the quartz, either before or after grinding. The white silica obtained by this process may be used for finishing paper, textiles, and other materials.—J. B. C. K.

Soluble glass; Manufacture of—R. M. Caven, Nottingham. Eng. Pat. 106,247, Jan. 17, 1917. (Appl. No. 874 of 1917.) Addition to Eng. Pat. 11,848, Aug. 21, 1916.

A FINELY-SUBDIVIDED alkaline silicate, which has been ground in the dry state, is mixed with from 25 to 38% of its weight of water, and heated to a temperature above 70° C. but below 100° C., until the mass becomes vitreous and miscible with water. The product is a hard solid, almost as vitreous as the original silicate, which can be ground to powder, and when stirred up with water mixes with it easily, only about 1.5% remaining insoluble.—J. B. C. K.

Alkali percarbonates; Process of manufacturing—O. Liebknecht, Frankfurt, Germany. Assignor to Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,225,832, May 15, 1917. Date of appl., Jan. 27, 1917.

HYDROGEN peroxide is allowed to react with an alkali carbonate in the presence of a restricted proportion of water, and common salt is added to bring about the direct separation of the crystalline percarbonate from the aqueous solution. A silicate of magnesium is also employed as a stabilising agent in the process.—J. B. C. K.

Alkali percarbonates; Process for rendering stable. A. Schaidhauf, Frankfurt, Germany. Assignor to Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,225,872, May 15, 1917. Date of appl., Jan. 16, 1917.

SOLID alkali percarbonates and solutions of the same, are rendered stable by incorporating with the percarbonate, during manufacture, silicic acid combined as a silicate, and gum-arabic.—J. B. C. K.

Potassium cyanide; Process of securing from water-insoluble potassium-containing minerals. J. H. Reid, Newark, N.J. U.S. Pat. 1,226,811, May 22, 1917. Date of appl., Sept. 30, 1915.

MINERALS containing potassium silicate, such as feldspar, are mixed with a carbide, and are then exposed to the action of an electric current, in the presence of nitrogen. The potassium cyanide which forms as a result of the electro-thermal action, is volatilised and condensed.—J. B. C. K.

Potassium compounds; Process of securing water-soluble—from water-insoluble potassium-containing minerals. J. H. Reid, Newark, N.J. U.S. Pat. 1,226,812, May 22, 1917. Date of appl., Sept. 30, 1915.

MINERALS containing potassium silicate, such as feldspar or orthoclase, are mixed with calcium chloride, or some other chloride capable of reacting

with the silicate at high temperatures, and are then submitted to the action of an electric current of sufficient intensity to produce and volatilise potassium chloride.—J. B. C. K.

Hypochlorous acid; Manufacture of—W. N. Haworth and J. C. Irvine, St. Andrews, Scotland. U.S. Pat. 1,227,049, May 22, 1917. Date of appl., Feb. 19, 1916.

SEE Eng. Pat. 12,912 of 1915; this J., 1916, 1059.

Zinc sulphate; Process for producing from zinc ores. R. B. Llopert, Cordoba, Argentina. Eng. Pat. 100,245, Feb. 19, 1916. (Appl. No. 2506 of 1916.) Under Int. Conv., Apr. 2, 1915.

SEE U.S. Pat. 1,112,795 of 1915; this J., 1915, 834.

Titanic oxide; Manufacture of from a substance containing it. H. Wade, London. From The Titanium Alloy Manufacturing Co., New York. Eng. Pat. 106,428, Nov. 22, 1916. (Appl. No. 16,766 of 1916.)

SEE U.S. Pat. 1,206,798 of 1916; this J., 1917, 84.

Titanic oxide; Manufacture of from titaniferous-ferruginous substances. H. Wade, London. From The Titanium Alloy Manufacturing Co., New York. Eng. Pats. 106,584 and 106,585, Nov. 22, 1916. (Appl. Nos. 16,764 and 16,765 of 1916.)

SEE U.S. Pats. 1,206,797 and 1,206,796 of 1916; this J., 1917, 84.

VIII.—GLASS; CERAMICS.

Barium glasses; Notes on—A. E. Williams and S. F. Cox. Trans. Amer. Ceram. Soc., 1916, 18, 315—342.

THE influence of barium compounds in glasses has been reviewed by A. Silverman (this J., 1915, 399), who showed that barium may replace lime or lead to any extent and that it imparts a greater brilliancy and plasticity than lime. The authors made 42 glasses varying in composition from 1.0RO, 2.5SiO₂ to 1.0RO, 5.5SiO₂, i.e., from a Jena soft crown glass to a dense barium crown glass, from a mixture of flint, zinc oxide, 58% soda ash, potash, and precipitated barium carbonate. The soft glasses were melted and kept for 6 hrs. at 1450° C. and the harder ones at 1550° C. and were then poured into a hot iron mould and annealed from 500° C. to atmospheric temperature in 12 hrs. The potash-barium glasses showed a decided increase in brilliancy with increased proportions of barium; those with no soda and 0.5BaO have a better lustre than some high-class cut glasses. As the SiO₂ and BaO increase, the glasses become more refractory and those containing 1.0RO, 5.5SiO₂ were too viscous to be poured from the crucible at 1550° C. Glasses high in BaO poured best and remained viscous longer than others. The most workable glasses contained 0.1—0.5 BaO in 1.0RO and 2.5—4.5 SiO₂. The highest density was obtained in conjunction with high BaO and low SiO₂, which agrees with Winkelmann and Schott's general formula for calculating the density of glasses. The expansibility of all the glasses was low for boron-free glasses. For determining the solubility of the glasses, accurately ground plates, 8 cm. × 4 cm. × 0.35 cm., were used. The surface-area of these was measured and the pieces were then cleaned thoroughly and soaked in distilled water for 48 hours. They were then placed in porcelain dishes with 200 c.c. of distilled water and kept at 80° C. for 24 hours, the atmosphere of the oven being kept saturated with moisture so as to prevent evaporation. The water

was then transferred to a platinum dish and evaporated to dryness and the residue weighed. Most of the glasses containing 0.1 to 0.5 BaO in 1.0 RO and 2.5—5.5 SiO₂ were sufficiently insoluble, all those containing 0.3—0.5 BaO in 1.0 RO and 2.5—5.5 SiO₂ being highly insoluble. Increasing the BaO lessens the solubility much more than raising the SiO₂.

To determine the devitrifiability, pieces of glass were placed on asbestos and heated to 500° C. in a muffle. They were then cooled at a predetermined rate, examined, re-heated to 600° C., cooled as before, and again examined, this process being repeated until they had been heated five times, each time to a higher temperature than before. None of the glasses showed complete devitrification, but some of those containing 4.5—5.5 SiO₂ were devitrified superficially after being re-heated to 700° C. or above, this being attributed to the partial volatilisation of soda or potash. Hence BaO does not cause devitrification. The softening point of the glasses was determined by noting the temperature at which a vertical platinum rod weighted to give a load of 6.39 grms. per sq. cm. began to penetrate the surface; a gradual increase in the refractoriness of the glass accompanied increased BaO, this oxide hardening the glass much more than SiO₂.

The change of viscosity with temperature was estimated from the rate at which the platinum rod just mentioned penetrated the glass whilst the temperature was rising steadily, the rate of dropping being plotted against the rise in temperature on a graph. The "viscosity range" was taken as the difference in temperature between the softening point and the point at which the tangent of the curve had a slope of 60°, as at this point each glass reaches the same degree of viscosity and changes it at a constant rate. The "viscosity-range" does not vary regularly with any constituent, but decreases and increases alternately. The figures obtained for the rate of change of viscosity (*i.e.*, the amount the rod dropped when the temperature rose the equivalent of 1 millivolt) are more reliable than those for the viscosity itself. It was found that replacing sodium by barium decreases the rate of change of viscosity and increases the "viscosity range" except when all the sodium is replaced, when a slight decrease of "viscosity range" is shown.—A. B. S.

Boric acid; Determination of — in special glasses
P. Nicolardot and J. Boudet. Bull. Soc. Chim., 1917, 21, 97—101.

A MODIFICATION of the method which has been attributed to Hönl and Spitz (this J., 1896, 742), but which, in reality, is much older (see Klein, Bull. Soc. Chim., 1878, 29, 195) is recommended:—One gm. of the powdered glass is gently fused in a platinum crucible with 5 grms. of a mixture of alkali carbonates, and the melt disintegrated with hot water, and boiled for 5 mins. with 5 grms. of ammonium chloride. The silica is then precipitated by means of a current of carbon dioxide (10 mins.), and the liquid is boiled to remove ammonia, and then allowed to stand. The precipitate will contain the silica and all the metallic oxides (ZnO, CaO, Al₂O₃, MgO), whilst the boric acid remains in solution. The precipitate is washed with water containing a little ammonium chloride, and the filtrate and washings are mixed with 5 grms. of pure sodium hydroxide, then heated to remove ammonium salts, and evaporated to 100 c.c. The liquid is transferred to a 500 c.c. flask, and neutralised with hydrochloric acid, with methyl orange as indicator, after which it is boiled for 15 mins. beneath a reflux condenser to remove carbon dioxide. After cooling, one drop of methyl orange solution is added, and the liquid is titrated with N/10 sodium hydroxide solution free from carbon dioxide until yellow again, when

10 c.c. of glycerol, or of a freshly prepared solution of mannitol (0.8 grm.) in boiling water, is added, and the titration completed, with phenolphthalein as indicator. The presence of magnesia or alumina does not interfere with the determination of boric acid by this method, nor by the method of distilling it as methyl borate.—C. A. M.

Kaolin refining. I. E. Sproat. Trans. Amer. Ceram. Soc., 1916, 18, 767—811.

ONLY a portion of the discolouring particles is removed by the customary methods of refining kaolin, as they are small enough to pass even a 260 mesh sieve and are often so coated with clay that they cannot be separated by simple blunging. The suggested method consists of a preliminary crushing of the moderately dry clay (wet clay is very difficult to treat if the proportion of dry clay in it is not accurately known) through corrugated rolls, followed by a thorough blunging or grinding in ball mills with water and caustic soda. Two or even three blungings may be necessary and the soda must be added at a constant rate of about 10 c.c. per sec. The slip is passed through concrete troughs, each at least 125 ft. long, 2 ft. wide at the inlet end, and sufficiently wide at the outlet for the slip to be only about 1 in. deep. These troughs must be quite level, with smooth sides and a slightly rough but uniform bottom. The liquid which flows from the troughs is mixed with exactly sufficient sulphuric acid to neutralise the soda originally added; this flocculates the clay. The fluid is then run through a riffled trough, 50 ft. × 1 ft. × 1 ft., with a slope of 1:50, so as to cause a rapid flow, and then through a rotary screen of 120-mesh and into concrete settling tanks, each 75 ft. × 25 ft. × 5 ft. The clay settles within 24 hrs., and after the supernatant water has been run off, the thick slip is filter-pressed, the resulting cakes being dried by steam. The cost of the treatment is stated to be 1s. 6d. per ton. The following precautions are important:—The clay and water must be fed at a uniform rate. Double blunging is essential; insufficient blunging causes failure. The amount of caustic soda added must be adjusted to the clay. A constant viscosity of about 1.068 (referred to that of water as 1) must be maintained in the slip at the head of the trough. The slip should be agitated before it enters the final trough. Only just sufficient acid to neutralise the soda should be added.

Georgia kaolin treated by this process can be substituted for all the English china-clay and a portion of the ball clay used in American pottery.—A. B. S.

Ball clays; Physical properties of some — and their effects on porcelain bodies. T. A. Klinefelter. Trans. Amer. Ceram. Soc., 1916, 18, 93—105.

IN an attempt to find an American substitute for English ball clays, various clays were ground so as to pass through an 18—20-mesh sieve and were made into plain slips containing only clay and water, and body slips containing clay 50%, flint 30%, and felspar 20%, and water. These slips were allowed to stand for 24 hours and were then blunged three or four times for several minutes each time. Some clays, such as Sant's English No. 1, Knowles' No. 12, and the Kentucky Construction Co.'s Special and Black clays slaked readily with much less water than other clays, such as Tennessee No. 3. Slips containing English or very similar American clays left a larger residue on a 150-mesh sieve (Tyler's Standard) than slips made from the same clays on a manufacturing scale. To avoid this discrepancy, the bodies were ground in small ball-mills. The screened slips were placed in plaster moulds lined with cambric and the paste so produced was kept in a damp place for about 3 days to obtain a workable plastic

mass. The water-content of the paste varied greatly on account of the personal factor. The paste was cut into pieces about 5 in. \times 1½ in. \times 1 in. and three pairs of shrinkage marks 5 cm. apart were placed on each. These pieces were allowed to dry for an hour, turned on end, and dried in a commercial dryer, and then the shrinkage marks were re-measured. The shrinkage of different pieces of the same clay, and even of different parts of the same piece, varied up to 4%, especially when some of the test-pieces were thinner than others, but the average variation did not exceed 1%. The variations in the shrinkage of the body mixtures was less than in that of the clays, but even with bodies made on a large scale the handling when in the plastic state and the varying humidity in the dryers caused a variation in shrinkage in different parts of the same surface of a given piece. The shrinkage on burning showed similar variations. In comparing different ball clays or bodies made from them, errors may easily arise through (i.) imperfect sampling, (ii.) insufficient blunging, (iii.) unsuitable consistency or irregular texture, (iv.) uneven packing when making test-briquettes, (v.) variations in the humidity of the dryers, and (vi.) the position of the pieces in the kiln and resulting variations in the burning temperature. —A. B. S.

Fineness of [ceramic] raw materials; Determination of the —. F. W. Walker, jun. Trans. Amer. Ceram. Soc., 1916, 18, 499—507.

100 GRMS. of the material, dried at 100°C., is mixed with water and the finer particles are gently washed through an 8-in. W. S. Tyler standard sieve of 280-mesh, the residue being dried at 75°C. The residue is then placed in the top of the following Tyler standard sieves arranged one above another: No. 115 (0.0049 in. opening), No. 150 (0.0041 in.), No. 170 (0.0035 in.), No. 200 (0.0029 in.), and No. 280 (0.0020 in.). The set of sieves is then rapped in a "Tyler" Ro-tap machine for 69 mins., after which a "one minute" test is made and the amount of material passing through a No. 280 sieve is ascertained. The residue on each sieve is weighed and the results are plotted on a graph with the cumulative percentages of residue as ordinates and the sizes of opening in the sieves as abscissae. —A. B. S.

Felspar-calcite and felspar-magnesite: Fusion study of the mineral systems —. F. A. Kirkpatrick. Trans. Amer. Ceram. Soc., 1916, 18, 575—618.

FROM observations on "cone-mixtures" heated in an electric furnace, the author concludes that with the system orthoclase-calcite there is a well-defined maximum on the deformation point curve with a mixture containing 27½% of calcite and two well-defined eutectics with 3% and 50% of calcite respectively. There appears to be no predominating compound in this poly-component system. The system orthoclase-magnesite shows one eutectic point at 3% of magnesite; beyond this the curve rises rapidly with increasing magnesite. The system albite-calcite shows a long eutectic range at 10—55% of calcite; beyond this the curve rises rapidly. The albite used was very impure. With the system albite-magnesite also, there was a long eutectic range, at 5—20% of magnesite, the effect of magnesia being, however, less than that of lime. The lowest fusion point with mixtures containing calcite occurs at cone 01 (1080°C.) with 25% calcite and 75% albite; the lowest fusion point with mixtures containing magnesite occurs at cone 14 (1105°C.) with 15% magnesite and 85% albite. Orthoclase and albite appear to be decomposed by calcite but not by magnesite. The best types of Bristol glazes lie in eutectic areas of the orthoclase-calcite system. A list of 80 references to the behaviour of analogous mixtures is given. —A. B. S.

Potash-felspar-steatite mixtures; Softening points of —. W. S. Howat. Trans. Amer. Ceram. Soc., 1916, 18, 488—491.

MIXTURES of steatite and Maine felspar or a selected microcline felspar were made into small cones and heated in an electric furnace rapidly to 800°C. and afterwards at the rate of 2½°C. per minute until they deformed. It was found that with either kind of felspar the eutectic contained 17—23% of steatite. —A. B. S.

Fireclay body: Effect of non-plastic materials on the shrinkage and mechanical strength of a No. 3 —. W. C. Millsom, H. S. Robertson, and C. C. Treischel. Trans. Amer. Ceram. Soc., 1916, 18, 524—531.

A No. 3 fireclay from Macomb, Ill., was mixed with broken sewer pipe, local crushed rock, and a calcined clay made by heating the fireclay to 600°C., all the materials being ground separately and passed through a No. 10-mesh sieve. The mixtures were ground in a wet pan for 5 mins., and transferred to a small pug-mill fitted with a 2½ in. pipe-mouthpiece. The pipes produced were cut in 12 in. lengths, allowed to dry for 2 or 3 days, and then set upright in a small rectangular down-draught kiln. Four briquettes were simultaneously made in a small dry-press and were used for measuring the shrinkage. During the burning the temperature rose steadily from cold to cone 4—5 (1170°C.) in 20 hrs. and was then kept constant for 3 hrs., a good, thick bed of fire being maintained. About 10 lb. of salt was then scattered over each fire in turn, this salting being repeated three times at intervals of 1—2 hours, and the temperature raised to cone 4 after each salting. A final dose of salt was given to both the kiln fires simultaneously, after which the fires were closed and the dampers lowered until the kiln was cold. The ware was completely vitrified and but little inferior to commercial salt-glazed ware. Some of the pieces cracked on account of the excess of sand present. The mixtures with the highest modulus of rupture ($M = \frac{0.96Pd}{lt}$, where P is the load required to

crush the tile, d is the mean diameter of the tile, l is the length, and t the thickness of wall) consisted of clay with 20—40% of broken pipe, the addition of sand not increasing the strength. The smallest shrinkage occurred in the mixtures of clay and broken pipe and of raw and calcined clay. The authors conclude that added sand is an undesirable constituent of a clay for drain pipes and that the reduction of shrinkage should be effected by the use of calcined clay rather than sand, when this can be done without spoiling the glaze. —A. B. S.

Fireclay bodies; Mechanical strength of — after repeated heating. F. A. Kirkpatrick. Trans. Amer. Ceram. Soc., 1916, 18, 545—556.

TO study the deterioration of fireclay bodies on repeated heating, mixtures containing equal weights of grog and clay were made, the kind of clay being different in each mixture. All the 1200 test-pieces were burned simultaneously, the rate of heating being about 50°C. per hour. The temperature reached in the first burning was cone 7 (1230°C.), in the second burning cone 10 (1300°C.), and in the remaining burnings cones 13—15 (1380—1435°C.), with a final "soaking" for 4—6 hrs. at the maximum temperature. Except in the first burning, the pieces were set on edge, with a small space between, and were exposed to the open fire, many of them becoming glazed with kiln-dust. The average moduli of rupture and the average deviation from the mean show that the strength of all the mixtures increased during the second burning, but decreased in the third to the tenth burnings, with occasional intervening slight increases in some cases. The apparent sp. gr. and porosity decreased

(though irregularly) on repeated heating. The relation between the modulus of rupture and porosity is generally parallel but not wholly consistent. Neither porosity nor apparent sp. gr. is changed much after the fourth burning at the temperatures mentioned. An open-grained and tough New Jersey fireclay showed the most constant results, and a brittle, close-grained St. Louis mixture showed the widest variations and became useless through cracking after the fifth burning.—A. B. S.

Clays for grog; Methods of calcining — C. B. Harrop. Trans. Amer. Ceram. Soc., 1916, 18, 165—179.

AFTER reviewing the various types of kilns used for the production of grog, the author recommends that the clay be burned in lumps in a continuous kiln with small chambers. He finds that the *Etagenofen* type is excellent except for the amount of labour required in working the material along the horizontal flue from the bottom of the upper to the top of the lower chamber. Shaft kilns choke too readily but might be improved by drawing or blowing air mechanically through the material. Inclined rotary kilns as used for cement are too costly for burning clay.—A. B. S.

Chemical porcelain. E. T. Montgomery and M. G. Babcock. Trans. Amer. Ceram. Soc., 1916, 18, 88—92.

CHEMICAL porcelain does not differ essentially from other hard-paste porcelain except that it may be more aluminous and less silicious. For many laboratory purposes, vessels made of china are quite satisfactory, but true "chemical porcelain" must (A) withstand rapid changes in temperature; (B) be thin, vitreous, and translucent; (C) the glaze must be so hard that when the ware is heated on a pipe-clay triangle with a blast burner, neither the triangle nor the contents of the vessel adhere to the glaze; (D) the glaze must resist alkaline solutions; and (E) the ware must not be deformed below a temperature corresponding to Seger cone 25 (1580° C.). The biscuit ware may be fired at a low temperature, but the glost ware requires cone 16 (1460° C.). Of nine mixtures tried, the best body consisted of clay 80%, felspar 10%, and quartz 10%.—A. B. S.

Pyrometer tubes; Notes on the manufacture of porcelain — W. L. Howat. Trans. Amer. Ceram. Soc., 1916, 18, 268—270.

AN analysis of a Marquardt porcelain tube from which the glaze had been removed showed SiO_2 35.12%, Al_2O_3 63.20%, and K_2O 1.65%. This was matched by a body composed of grog No. 1, 45.7; grog No. 2, 7.3; North Carolina kaolin, 17.0; Florida kaolin, 5.0; Tennessee ball clay, 15.0; and English china clay, 10.0 parts. Grog No. 1 was composed of calcined alumina 70, North Carolina kaolin 22, and potash spar 8%. Grog No. 2 was composed of potash spar 64, and calcined alumina 36%. Each grog was calcined at cone 19 and crushed so as to pass a 120-mesh sieve. The body was wet-ground in a ball-mill and filter-pressed. Tubes made by extrusion warped badly, but those cast in simple plaster moulds were quite satisfactory. The casting slip was made by adding sodium carbonate and silicate to the filter-pressed body and blunging the mixture with water. The slip had a sp. gr. of 1.874 and 200 c.c. of it required 2 mins. to flow through the viscometer (U.S. Bureau of Standards). The tubes, suspended in special saggars, were biscuited at cone 05 (1000° C.), glazed with a mixture corresponding to (0.15 K_2O , 0.20 MgO , 0.65 CaO) 1.0 Al_2O_3 , 10.0 SiO_2 , and burned at cone 17 (1480° C.). The tubes compared favourably with those made at the Marquardt factory, but would be improved by a more refractory glaze.—A. B. S.

Tunnel kiln; A continuously operated — for high-grade clay ware. L. E. Barringer. Trans. Amer. Ceram. Soc., 1916, 18, 106—123.

A DESCRIPTION of the Didier-March kiln at Keasbey, N. J., is given. It consists of a simple tunnel, 197 ft. long, with two furnaces on each side near the middle. The kiln holds 36 cars which carry the goods and are moved forward one car-length every two hours. Each car will carry 87 saggars 12 in. diam. by 6 in. high inside measurement. Three tons of coal is used daily for burning porcelain in saggars at 1400° C.; for burning firebricks at 1400° C. 6 cwt. of coal is required for each 1000 bricks. The labour cost is 10% less than for periodic kilns and the life of the saggars is 16% greater. Repairs cost the same as for periodic kilns with the same output.—A. B. S.

Clay trials; Methods for saturating — for absorption and porosity determinations. M. F. Beecher. Trans. Amer. Ceram. Soc., 1916, 18, 73—79.

AFTER reviewing published methods and making a series of tests, the author concludes that for ordinary laboratory determinations of porosity and absorption, saturation by boiling in water for 45—60 mins. is sufficiently accurate. Where exceptional accuracy is required, the most effective means of saturation consists in immersing the samples in boiling water and subjecting them to a vacuum of 29 in. mercury for 3 hrs. and then immersing them in water at room temperature for 96 hrs. The customary method of immersion in cold water gives low results, even after a week's soaking. Immersion in cold water with subsequent subjection to a vacuum also gives low results.—A. B. S.

Drain tile [pipes]; Comparison between sodium sulphate and freezing tests for — H. F. Staley. Trans. Amer. Ceram. Soc., 1916, 18, 612—683.

THE author found that the following method is quicker, more convenient and more economical than any other freezing or sulphate tests he has tried, one treatment by this process being equal to two treatments by the customary method of freezing the tile whilst partially immersed. Samples were immersed in a 15% solution of sodium sulphate at 21° C. (70° F.) for 48 hrs., then placed in a dryer at 110° C. for 7 hrs. Subsequent treatments consisted in immersing the samples in the solution for 16 hrs. and then placing them in the dryer for 7 hrs., the intervening hour in each 24 hrs. being used for transferring and examining the samples. The method is inapplicable to concrete articles as the sulphate attacks cement.—A. B. S.

Dryer-scum [on clay products]; Dissociation of calcium sulphate and the removal of — A. E. Williams. Trans. Amer. Ceram. Soc., 1916, 18, 271—276.

DRYER scum is customarily removed by finishing the burning of the goods under reducing conditions, but this tends to spoil the colour of red ware. The author's experiments showed that at 800° C. in the presence of a high percentage of carbon monoxide, gypsum mixed with 4 times its weight of clay is completely and rapidly reduced. Bricks scummed during drying were burned in an oxidising atmosphere at 700° C. and then for 6 hrs. in a reducing atmosphere at 700—800° C. The kiln-gases contained 2% of oxygen and in one case 1½%, and in the other 4% of carbon monoxide. The firing was finished under oxidising conditions at 1000° C. No improvement resulted. It was found that the customary use of barium carbonate is effective, and that it can be satisfactorily replaced by barium fluoride, hydrated barium hydroxide, sodium oxalate, and sodium fluoride.—A. B. S.

Slags [from coal ash]; Method of testing the corrosive action of — on firebrick. G. H. Brown. Trans. Amer. Ceram. Soc., 1916, 18, 277—281.

A SLAG may penetrate a firebrick by capillary attraction as well as by dissolving the brick-material. Hence the author objects to the customary method of placing the slag in a depression in a firebrick or in a cell cemented to the brick, and prefers to place the bricks on end in fireclay boxes, each 9 in. \times 8 in. \times 3 in. internally, and burned at cone 12 before use. The bricks are packed on two sides with finely-ground slag and the boxes with their contents are heated in a down-draught kiln at a temperature reaching 1400° C. in 36 hrs., reducing conditions being maintained during the last 12 hrs. In this manner, a considerable portion of the brick is subjected to the action of the slag and structural defects are readily detected. The use of so large an amount of slag reduces errors due to changes in its composition and facilitates a study of the time-effect. The author found that the slag prepared from coal ash and also a synthetic mixture of similar composition vigorously attacked silica and bauxite bricks, penetrating to the centre and producing a honey-comb structure. A magnesite brick showed penetration to the centre and considerable solution at the surface, whilst a carborundum brick showed no penetration but excessive surface solution. Some brands of clay bricks were not attacked at all, but others which were under-burned or contained coarse grog were irregularly penetrated.—A. B. S.

Terra-cotta glazes; Influence of variable silica and alumina on —. R. B. Keeler. Trans. Amer. Ceram. Soc., 1916, 18, 282—311.

IN opposition to Seger, the author considers that no ratio between the silica and alumina can be correct for all the RO combinations in glazes, and that within wide limits any RO will form a glaze if the proper proportions of silica and alumina are present and the glaze is properly heated. For ordinary terra-cotta glazes the following limits are safe:—0.2—0.4KNaO, 0.1—0.6CaO, 0.1—0.4ZnO, 0.02—0.1MgO, 0.02—0.3BaO, 0.0—0.6PbO, 0.2—0.5Al₂O₃, 1.5—4.0SiO₂, and 0.02—0.15SnO₂. Experiments in which the RO, Al₂O₃, and SiO₂ were all varied showed that high alumina and low silica usually produce immature glazes which, when they fuse, tend to flow and to craze. Low alumina and low silica induce crazing, pinholes, and immaturity, and stannic oxide is not dissolved. High silica and alumina produce beading, immaturity, and waviness but no crazing. Low alumina and high silica give fairly bright glazes which show waviness and become rougher if the alumina is increased. Glazes and matts containing 0.1PbO and low felspar, with 0.2 to 0.35 Al₂O₃ and 1.5 to 2.25 SiO₂ are good and cover the body well at cone 2 (1120° C.). Low felspar with high ZnO and MgO produces a good glaze above cone 3 (1140° C.), but the glaze must contain 0.35 Al₂O₃ and 2 SiO₂ for use at cone 3. High K₂O produces good, bright glazes with 0.4—0.5 Al₂O₃ and 2.4—2.9 SiO₂ at cone 4 (1160° C.). High MgO and ZnO and low K₂O limit the Al₂O₃ to 0.4—0.48 and the SiO₂ to 2.06—2.68 at cone 4, but with fairly high K₂O and less MgO and ZnO the fusing point is lowered, the alumina range is slightly increased, and the silica range changed to 2.4—2.9 SiO₂. Other experiments showed that, for good matt glazes, it is desirable to use a rather hard felspar, and a mixture containing at least 0.35 K₂O, less than 0.35 ZnO, and low CaO. For clear glazes, 0.3 K₂O, 0.3 CaO, 0.3 ZnO, 0.05 BaO, and 0.05 MgO is good at cone 4. The materials, duration of burning, and time of cooling influence the results, and glazes made of the same materials but derived from different sources differ widely in their behaviour.—A. B. S.

Bristol glazes compounded on the norm basis; A study of —. A. S. Watts. Trans. Amer. Ceram. Soc., 1916, 18, 424—430.

STALEY (Trans. Amer. Ceram. Soc., 1911, 13, 126; compare Purdy, this J., 1912, 1128) has shown that the classification of glaze compositions into "norms" reduces the study of glazes to that of a three-component system. Ordinary Bristol glazes contain the following oxides:—K₂O and Na₂O introduced as felspar (a mixture of microcline and albite); CaO introduced as whiting, CaCO₃; zinc oxide, ZnO; Al₂O₃ introduced in felspar and kaolin; SiO₂ introduced in felspar, kaolin, and as free silica (flint). The minerals which would normally form in Bristol glazes are microcline (K₂O, Al₂O₃, 6SiO₂), albite (Na₂O, Al₂O₃, 6SiO₂), anorthite (CaO, Al₂O₃, 2SiO₂), wollastonite (CaO, SiO₂), willemite (2ZnO, SiO₂), and sillimanite (Al₂O₃, SiO₂). Two series, each containing 45 mixtures, were prepared to correspond to mixtures of (i.) felspar, willemite, and wollastonite and (ii.) felspar, willemite, and anorthite.

Series I. The temperature of deformation of the various components and eutectics was: felspar, cone 6 (1250° C.); willemite, cone 13 (1390° C.); wollastonite, cone 8 (1290° C.); felspar-willemite eutectic (0.525Na₂O, 0.225K₂O, 0.250ZnO, 0.75Al₂O₃, 4.625SiO₂, cone 2 (1170° C.); willemite-wollastonite eutectic (0.5CaO, 0.5ZnO, 0.75SiO₂), cone 5—6 (1240° C.); and one ternary eutectic (0.175Na₂O, 0.075K₂O, 0.375CaO, 0.375ZnO, 0.25Al₂O₃, 2.06SiO₂), deformed at cone 1 (1150° C.). The glazes of this series do not opacity if 0.5 or more equivalent of felspar is present or unless the willemite exceeds 0.25 equivalent. At cone 4, the mixtures approaching the ternary eutectic have a brilliant gloss and towards the willemite end of the triaxial diagram a satin-like texture is developed; the other mixtures are matt or pinholed.

Series II. The deformation point of anorthite is cone 18 (1500° C.); of the willemite-anorthite eutectic (0.25CaO, 0.75ZnO, 0.25Al₂O₃, 0.875SiO₂) cone 5 (1230° C.). The lowest deformation temperature is that of the felspar-willemite eutectic shown in Series I. Mixtures containing less than 0.25CaO or more than 0.25ZnO tend to be opaque. Crazing only occurs with mixtures containing more than 0.5 felspar or less than 0.25 CaO. All the glazes in this series are matt.

The fusion point of Bristol glazes is lower if the lime is present as wollastonite than if it is introduced as anorthite. The presence of willemite also reduces the maturing temperature of the glaze. A low felspar content is necessary to avoid crazing and more than 0.25 willemite must be present to make the glazes glossy.—A. B. S.

Bristol glazes compounded on the eutectic basis; Study of —. A. S. Watts. Trans. Amer. Ceram. Soc., 1916, 18, 631—641.

THE most fusible mixture of modern Bristol glaze type was found to be produced by mixing Canadian felspar 59.02, whiting 8.03, zinc oxide 6.59, Florida kaolin 13.81, and flint 12.04%, corresponding to (0.4KNaO, 0.3CaO, 0.3ZnO)0.60Al₂O₃, 3.55SiO₂. It deformed at cone 03 (1040° C.). Glazes were made of this and allied mixtures and burned at cone 03—01 (1040°—1080° C.) and cone 4 (1160° C.), and it was found that there is a rapid increase of glossiness with a slight increase of felspar, greater white opacity with more ZnO, and a greater cream opacity with more CaO. Allowance must be made for a slight volatilisation of the ZnO.—A. B. S.

Bristol glazes; Effect of clay on the fusibility of —. E. C. Hill. Trans. Amer. Ceram. Soc., 1916, 18, 508—518.

THE results of experiments by R. C. Purdy (this J., 1903, 1047) on Bristol glazes showed that in glazes composed of felspar, whiting, zinc oxide, clay,

and flint, the amount of clay which gave the most fusible glaze decreased as the felspar increased at the expense of the whiting, so that the most fusible glaze produced by him (1035° C.) contained 0.4 felspar, 0.2CaO, 0.4ZnO, 0.08 clay, and 0.08 flint. Purdy also found (this J., 1911, 1385) that for porcelain glazes made of the same materials and with an $\text{Al}_2\text{O}_3 : \text{SiO}_2$ ratio of 1 : 6, increase of clay decreased the fusibility. As these experiments left some doubt as to the amount of clay required for different proportions of CaO and ZnO to form a fusible glaze, the author planned a series of glazes to cover additions of clay between the ones used in Purdy's two series. He found that with an $\text{Al}_2\text{O}_3 : \text{SiO}_2$ ratio of 1 : 6 and CaO : ZnO = 3 : 1, any addition of clay up to 0.3 equiv. makes the glaze more fusible and confirms Purdy's results, but with CaO : ZnO = 1 : 1, clay increases the fusibility up to 0.02 equiv. and further additions decrease it. The author found that glazes containing 0.30 equiv. of clay are more refractory than any containing less clay or none, though Purdy has stated that this equiv. of clay is present in the most fusible glaze of its type. With CaO : ZnO = 1 : 3, the glaze with 0.05 equiv. clay is only slightly more fusible than those free from clay, and any further addition makes the glaze more refractory. Hence, within the limits studied, the most fusible glazes were those with a CaO : ZnO ratio of 3 : 1 and an increase of either base reduced the fusibility. An increase in the proportion of silica increases the fusibility, but the clay must then be lower to secure a readily fusible glaze. The author points out that if Purdy had added silica instead of clay to his earlier series of glazes the fusibility would have been greatly increased and that the fusing point of these glazes would have been higher if clay alone and not a mixture of clay and flint had been used. He agrees with Purdy that in glazes devoid of ZnO the clay must be present in 0.3 equiv. (irrespective of the silica ratio) in order to have the maximum fusibility, but adds that with the lowest SiO_2 used (2.0 equiv.), increase of clay up to 0.3 did not increase the fusibility. With each increase of SiO_2 , however, up to that giving the most fusible mixture, the effect of clay in increasing the fusibility was greatest with 4.0 SiO_2 .—A. B. S.

Leadless glazes; Fritted — for sanitary ware.
C. W. Parmelee and G. A. Williams. Trans. Amer. Ceram. Soc., 1916, 18, 812—841.

For sanitary ware burned at cone 7 (1230° C.) the best range of RO in the glaze was found to be within the following limits:—0.4—0.6 K_2O , 0—0.3ZnO, and 0.4—0.6CaO, the other oxides being 0.5—0.6 Al_2O_3 , 5 SiO_2 , 0.5 B_2O_3 . The use of soda instead of potash increased the range within which good glazes could be obtained. Glazes within the limits mentioned do not readily craze, but become opalescent with an excess of alkali or boric acid. The best glaze obtained was composed of:—*Frit*: nitre 1212, whiting 400, flaky boric acid 1860, and flint 2520; *mill batch*: frit 1450, whiting 366, felspar 1671, Florida clay 516, and flint 240.
—A. B. S.

Enamels; An attempt to fit — to plastic clay bodies. F. A. Kirkpatrick, H. C. Arnold, and C. F. Geiger. Trans. Amer. Ceram. Soc., 1916, 18, 139—164.

THE authors have endeavoured to apply an enamel coating to a stiff, plastic column of clay extruded through a die, the column being afterwards cut into bricks. To secure a perfect fit between glaze and clay there must be sufficient adhesion between them and they must both shrink to the same extent and at the same rate. The enamels were ground wet in ball-mills for 2 hrs. and were then passed through a 100-mesh sieve. The percentage of water in each was determined and

various electrolytes and water were then added and the mixtures were shaken by hand for 3 mins. The viscosity of each slip was determined in an Ostwald viscometer. The following methods for regulating the shrinkage of the enamel and its adhesion to the clay were used:—*Precipitation of colloidal silicates* in the enamel. Sodium silicate solution and afterwards either magnesium or aluminium chloride solution in the proportion of 65 : 35 were added to the wet enamel. Decrease of viscosity occurred with small amounts of the reagents, but an increase with larger additions, particularly in the mixtures containing aluminium chloride. The enamels so treated had too little shrinkage and adhesion and flaked on drying. *Coagulation by salts*: Divalent ions from MgSO_4 and CaCl_2 gave the least increase in viscosity; the trivalent ion from $\text{Al}_2(\text{SO}_4)_3$, AlCl_3 , or alum gave greater viscosity, and the stannic ion from SnCl_4 gave the greatest viscosity. The effect of zinc chloride resembled that of trivalent and quadrivalent rather than of divalent ions. All these enamels flaked or cracked in use. *Coagulation by acids*: Hydrochloric, oxalic, and boric acids increased the viscosity but caused bad flaking and cracking. *Coagulation by alkalis*: The addition of up to 10% of sodium carbonate or borax increased the viscosity but the enamels lacked adhesion. *Precipitation of colloidal silica in the enamel* by adding a 9% solution of sodium silicate and then a 1.82% solution of hydrochloric acid or a 9% solution of oxalic acid, so that the mixture contained 80% sodium silicate, gave poor results with hydrochloric acid but good with oxalic acid, using 4—6% of the mixed reagents. The enamels then thickened greatly, some setting to a jelly. *Substituting calcium, barium, and zinc oxalates* for the oxides or carbonates of these metals in preparing the enamels doubled the viscosity and produced enamels which gave a large percentage of perfect trials, but the price of the oxalates is prohibitive. *Increase of clay content* to 35%, followed by the addition of 3—5% of sodium silicate and 1—3% of oxalic acid gave perfect-fitting enamels on one clay, and might be used with advantage in some cases. *Addition of organic colloids*. The addition of 1% of starch or of 0.3—0.5% of gum tragacanth proved to be the most readily applicable method of attaining the desired result. Glue was not satisfactory. The influence of time on the viscosity and adhesion of the enamel is important, but less so with mixtures containing sodium silicate and oxalic acid than with others.—A. B. S.

Ground-coats for sheet-iron enamels; Effect of variation in the composition of —. R. R. Danielson. Trans. Amer. Ceram. Soc., 1916, 18, 343—362.

IN an enamel corresponding to 0.25 K_2O , 0.5 Na_2O , 0.25CaO, 0.15 Al_2O_3 , 2.0 SiO_2 , 0.5 B_2O_3 , 0.25 Fe_2O_3 , part of the first three oxides was replaced by 0.01—0.04CoO or by 0.01—0.05NiO, or by 0.02—0.14 MnO_2 , or by equivalent mixtures of these oxides. The mixed materials were fritted in gas-fired crucibles, stirred to eliminate bubbles, and kept at the maximum temperature until free from undissolved matter. After about 3 hrs. the frit was poured into water, dried, mixed with 8% of ball clay and 1% of borax, the latter being added in hot solution, and ground in porcelain ball mills with 40% of water for 20 hrs. Trials were made on iron plates which had previously been scaled, pickled, washed, and dried. Increasing the CoO improved the quality and increased pinholes. Increasing the NiO decreased bubbling, but the enamels were not very smooth. Increasing CoO and decreasing NiO removed bubbling and gave a good texture. Increasing MnO_2 gave a very smooth enamel with some bubbles. Increasing CoO and decreasing MnO_2 reduced the number of fine bubbles.

Increasing SiO_2 or CaO increased pinholing. Decreasing B_2O_3 increased pinholing and blisters. Tests with a 1 lb. weight dropped from varying heights on the ground coats showed that CaO and NiO have similar toughening action, but MnO_2 decreases toughness. The addition of CoO or NiO to MnO_2 increases the toughness. The introduction of part of the flint into the frit increases the toughness, but makes the frit more refractory. Enamels with low B_2O_3 or high CaO are not satisfactory. Variations in SiH_2O_3 do not affect the toughness but alter the opacity. When a white coat is applied to the ground coat, CoO should be present in the latter. The best ground coats were obtained with a mixture containing 0.4% CoO and 0.75% NiO , which was heated on the steel until the enamel turned black. As NiO is cheaper than CoO the use of both oxides instead of cobalt oxide alone is desirable.—A. B. S.

Enamel; Heat-transmission of —. E. P. Poste. Trans. Amer. Ceram. Soc., 1916, 18, 570—574.

THE author endeavoured to ascertain the effect of the enamel itself and the influence of surface-condition on the transmission of heat through it by filling small cylindrical enamelled dishes, each 3 in. deep and 5 in. diameter, with water and noting the time required to evaporate 500 c.c. of water. Copper dishes required 140 mins., plain steel dishes 153 mins., enamelled steel (4 coats) 179 mins., when heated on a water-bath. With steam at atmospheric pressure the times were reduced to 106, 117, and 164 mins. respectively, whilst with steam under a pressure of 10 lb. per sq. in. they were only 16, 19, and 73 mins. The results show that enamelled steel transmits heat more slowly than the plain metal, the retardation being slight with hot water and much greater with steam under pressure.—A. B. S.

Report of the Refractory Materials Committee of the Institution of Gas Engineers. See 11A.

[Glass] pot; Reversible —. G. A. Shields. Columbus, Ohio. U.S. Pat. 1,226,022, May 15, 1917. Date of appl., Oct. 26, 1914.

AN integral reversible glass pot comprises two receptacles placed base to base and connected by a narrow neck in the centre, this forming an annular groove for an operating tool. A central boss projects from the bottom into each receptacle and an air duct extends through both bosses and the connecting neck.—W. F. F.

Hot-kiln. A. B. Klay, Modesto, Cal. U.S. Pat. 1,226,535, May 15, 1917. Date of appl., May 31, 1916.

THE heating chamber is provided with a series of openings in the bottom and a corresponding series of flues in the top, the openings in the bottom being connected with separate interconnected furnaces below. A number of stacks communicate with opposite sides of the chamber along its length, and means are provided in the top of the chamber, at a distance from the furnaces, for feeding the latter with fuel.—W. F. F.

Dental cement. J. E. Mahan, Swissvale, Pa., Assignor to L. S. Smith and Son Manufacturing Co., Pittsburgh, Pa. U.S. Pat. 1,226,232, May 15, 1917. Date of appl., June 13, 1916.

A DENTAL cement consists of zinc, bismuth, magnesium, and manganese oxides, and about 2.5% of copper silicate.—W. F. F.

Refractory bodies; Manufacture of —. H. F. Chappell, Assignor to Mineral Products Corporation, New York. U.S. Pat. 1,226,750, May 22, 1917. Date of appl., Nov. 15, 1916.

ALUNITE is calcined and then leached, and the

product, with or without an intimate mixture of fireclay, is heated to such a temperature as to cause the material to bind together.—W. F. F.

Abrasive material; Method of making —. H. T. Kalnus, Brookline, Mass., Assignor to The Exelon Co., Cambridge, Mass. U.S. Pat. 1,226,892, May 22, 1917. Date of appl., May 7, 1915.

THE substances from which the material is to be made, e.g., aluminous material, are fused in an electric furnace and poured in a thin stream on to a surface which is moved in such a way that the material solidifies in thin layers.—W. F. F.

Silicon carbide refractory articles. The Carborundum Co., Ltd., Manchester. From F. J. Tone, Niagara Falls, N.Y., U.S.A. Eng. Pat. 106,393, Sept. 11, 1916. (Appl. No. 12,827 of 1916.)

IX.—BUILDING MATERIALS.

Sands [for mortar]; Colorimetric determination of organic impurities in —. D. A. Abrams and O. E. Harder. Chem. Engineer, 1917, 25, 9—11. Analyst, 1917, 42, 217—218.

TWO hundred grms. of the dry sand is digested, with occasional stirring, for 24 hours, with 100 c.c. of 3% sodium hydroxide solution and the extract filtered. Ten c.c. of the clear filtrate is diluted to 50 c.c. with water and the colour compared in Nessler cylinders with that of a freshly-made solution of sodium tannate, which is prepared by mixing 10 c.c. of a 2% solution of tannic acid in 10% alcohol with 90 c.c. of 3% sodium hydroxide solution, and allowing the liquid to stand for 24 hours. From 1 to 10 c.c. of this solution is diluted to 50 c.c. with water for the comparison, and the colour value in parts of tannic acid per million of the sand, is 100 times the number of c.c. of the sodium tannate solution necessary to match the colour. This test has proved that there is a relationship between the amount of organic impurities and the colour values, and that sands with high colour values give low results in mortar tests. Approximate comparisons between the colour values of sands and the strength of the mortars made from them indicated that a colour value of 250 corresponded to a loss of about 10 to 20% of compressive strength in a 1:3 mortar; a value of 500 to a loss of 15 to 30%; 1000 to a loss of 20 to 40%; 2000, to 25 to 50%; and 3000 to 30 to 60% loss.—C. A. M.

Silica brick mixtures; Volume-changes of —. A. V. Bleiminger and D. W. Ross. Trans. Amer. Ceram. Soc., 1916, 18, 519—523.

THE amount of permanent expansion of silica bricks (9.375 to 9.438 in. per linear ft.) is usually considered the criterion of proper firing. For the complete conversion of quartz to cristobalite, the calculated expansion is 13.4%, but in practice this conversion is never complete and the formation of tridymite causes an additional expansion. The authors fired 2 in. cubes of a prepared silica brick mixture containing quartzite rock from Tyrone, Pa., U.S.A., to temperatures of 1200°—1500° C., with a temperature-rise of 20° C. per hour, the cubes being held at the maximum temperature for 4 hours. The original and subsequent volumes of the cubes were measured in a Seger's volumometer and the linear expansion was measured directly. The results show that expansion occurs at 1200° C., though no appreciable formation of

cristobalite occurs below 1250° C. Between these two temperatures there is a lag in the expansion curve, but beginning at 1300° C. the rate of expansion remains constant and is coincident with, but not proportional to, the formation of cristobalite. The most desirable burning temperature appears to correspond to a break in the expansion curve somewhat beyond 1530° C., (i.e., at about cone 20), but the experiments did not extend far enough to locate it. The amount of cristobalite after burning at 1350° C. was determined by sketching the outlines of the crystals by means of a microscope and camera lucida on thin paper, cutting them out, and comparing the weight of these pieces of paper with that which represented the microscope field. At 1300° C. not more than 5% of cristobalite and no tridymite were found. At 1350° C. the material consisted of 57.13% of cristobalite and a mixture of quartz and calcium silicate. At 1400° C. 72.17%, at 1450° C. 81.26%, and at 1500° C. 90% of cristobalite was present. Only small proportions of tridymite were observed. It seems evident that the volume expansion of the bricks is not proportional to the amount of cristobalite formed and it is somewhat greater than three times the linear expansion, the relation between the two not being quite so regular as is often assumed.—A. B. S.

Slag paving bricks. E. T. Montgomery and P. W. Burdick. Trans. Amer. Ceram. Soc., 1916, **18**, 492—498.

THE best slag bricks, hitherto, have been made from copper smelters' slag containing 47—57% SiO_2 , 5—18% Al_2O_3 , 3—10% Fe_2O_3 , 18—33% CaO , and 1—8% MgO . In a previous investigation (this J., 1914, 81) it was found that slag bricks should not contain less lime and magnesia than that represented by a slag composed of 52% of dolomite and 48% of shale. It was now sought to produce more fusible slags by the addition of fluxes. The most satisfactory slag was made of dolomite 60, shale 40, and 10 parts of a mixture of flourspar 65, cryolite 35 parts. The molten slag at 1258° C. was poured into iron moulds which had been washed inside with a clay-alumina mixture and then heated to 900° C. The bricks in the moulds were kept at this temperature for 2 hrs. and were then allowed to cool. The bricks gave better results in the rattler test than the ones usually adopted for the standard for paving bricks made of clay.—A. B. S.

sistency figure and the time of setting. The tensile strength of the plaster is increased by the addition of less than 4% of lime but is greatly decreased by larger amounts. An increase in the amount of water added to the plaster increases the time of setting and reduces the tensile strength. If the plaster is mixed in a room, the temperature of which is above 24° C., the tensile strength decreases in proportion to the increase of temperature above this figure.—A. B. S.

Note on the determination of dissociation points [of calcium carbonate and hydroxide and gypsum]. Montgomery and Groves. See VII.

Platinum situation in the United States. U.S. Commerce Report, No. 130, 1917.

THE quantity of platinum in the United States is estimated by the U.S. Geological Survey at 1,000,000 troy oz., besides which there is over 400,000 oz. of other metals of the platinum group, principally palladium, iridium, and rhodium. In 1916 the crude platinum mined in Colombia (25,000 oz.) was refined in the United States, and 28,088 oz. of metals of the platinum group was recovered by American refiners from all sources, foreign and domestic, of which 24,518 oz. was platinum.

The following table shows the world's production of crude platinum for the last 8 years in troy ounces:—

Plaster of Paris; Influence of variations in water, lime, and temperature on the setting of —. C. H. Kerr and R. J. Montgomery. Trans. Amer. Ceram. Soc., 1916, **18**, 180—191.

In testing plaster care must be taken not to disturb the material after setting has commenced as this may cause defective setting. Plaster of "standard consistency" will flow 16 in. down a rectangular copper-lined trough inclined at an angle of 30° from the horizontal. The number of c.e. required by 100 grms. of plaster to produce a mixture of this consistency is termed the "consistency figure." The addition of slaked lime or hydrated lime to the plaster increases the con-

It is estimated that 30,000 oz. of crude platinum containing 85% metal, will be produced in Colombia in 1917, and that the production of Russia and the United States will be considerably increased.

Apparently the normal requirements of platinum in the United States call for 165,000 oz. annually. The dental industry formerly used 25 to 30% of the supply, but a number of alloys are now being employed instead of platinum. The jewelry industry used 40 to 50% of the supply, but has voluntarily agreed to limit the use of platinum in jewelry for the duration of the war. The quantity of platinum in chemical laboratories in the United

States is probably not over 10 to 15% of the supply and is all recoverable.

In 1915 about 44,000 oz., or 4% of the apparent United States stock of platinum, was used in contact-process sulphuric-acid works. The output of contact-process plants has increased nearly 200% since 1915, and these plants, it is understood, are not yet working to their full capacity. Thus there is apparently no pressing need for a large supply of platinum by the sulphuric-acid industry.

Government laboratories seem to be well supplied with platinum utensils and are not in the market for platinum at present. The United States mints refine platinum, and doubtless have stocks sufficient to meet any immediate Government requirements. The United States Geological Survey is taking a census of stocks of unmanufactured platinum in the United States that can be considered as immediately available, from which it appears that there are supplies of platinum sufficient to meet such extensions of contact-process plants as may be required immediately and a surplus left for all ordinary requirements. Should new demands arise, however, expansion in the chemical industries may make necessary the further curtailment of platinum in the manufacture of jewelry.

Steel: Influence of the speed of cooling on the temperature of transformation of —. Portevin and Garvin. Comptes rend., 1917, 164, 885—888.

WITH a given steel and the same initial temperature of quenching, the temperature of transformation is lowered with increasing speed of cooling. With a low rate of cooling, the transformation point is well marked and troostite is formed, while with a high rate no break in the cooling curve is noticeable and martensite is obtained. In this case the transformation is only indicated on the cooling curve by comparison with a metal showing no transformation. The critical rate of cooling above which the sudden transformation does not take place varies for a given critical temperature with the composition of the steel and appears to have a maximum value for a steel of eutectic composition.—J. N. P.

Nickel and cobalt; Rapid method of determining — in ores and alloys. W. R. Schocher and A. R. Powell. Analyst, 1917, 42, 189—199.

NICKEL and cobalt are precipitated from an ammoniacal solution by potassium iodide, as hexammine nickelous iodide, $[\text{Ni}(\text{NH}_3)_6]\text{I}_2$, and hexammine cobaltous iodide, $[\text{Co}(\text{NH}_3)_6]\text{I}_2$, respectively, and in the presence of excess of iodide (0.6 gm. KI per 0.1 gm. of nickel and cobalt) beyond that required for complete precipitation the precipitates are sufficiently insoluble for quantitative work. The volume of strong ammonia solution (sp. gr. 0.88) should be at least two-thirds of the total liquid, which should not be much in excess of 80 c.c., and the required amount of potassium iodide in cold saturated solution should be added immediately after the ammonia to prevent oxidation of the cobalt. Since small amounts of nickel or cobalt (less than 2 mgrms.) do not give a precipitate within 10 to 15 mins. the method is not suitable for the detection of traces of these metals. The crystalline precipitate which can be rapidly filtered off, without the use of a filter-pump, is washed with a solution of potassium iodide (40 grms. per litre) containing 800 c.c. of ammonia solution. The washed precipitate is dissolved in hydrochloric acid, with the addition of sulphurous acid to remove the liberated iodine, the solution filtered, and the cobalt and nickel determined by the authors' alkalimetric method (this J., 1916, 656). Ferrous

salts in ammoniacal solution containing sufficient tartaric acid to prevent precipitation of hydroxide yield a white precipitate of hexammine ferrous iodide $[\text{Fe}(\text{NH}_3)_6]\text{I}_2$, whilst ferric salts are not precipitated under these conditions. Hence, in the presence of excess of tartaric acid (about ten times the amount of iron present) cobalt and nickel may be separated in this way from iron by a single precipitation. Manganous salts yield a white pentammine manganous iodide, $[\text{Mn}(\text{NH}_3)_5]\text{I}_2$, which is more stable than the ferrous salt. Manganese is less readily precipitated than nickel or cobalt, but is liable to be carried down with the iodide precipitates of those metals. It is therefore advisable to dissolve the mixed iodide precipitate in a small excess of dilute acid, add sodium acetate in excess, and re-precipitate the nickel and cobalt with hydrogen sulphide. Copper is not precipitated under the conditions described (i.e., in ammoniacal 4% potassium iodide solution), but with a higher concentration of iodide yields a blue crystalline tetrammine cupric iodide, $[\text{Cu}(\text{NH}_3)_4]\text{I}_2 \cdot 2\text{H}_2\text{O}$. In presence of nickel and cobalt, however, some precipitation of copper takes place simultaneously from weaker solutions. This copper may be separated by dissolving the mixed precipitate in dilute hydrochloric acid, when cuprous iodide is precipitated, with the liberation of iodine. The liquid is boiled, cooled, and filtered, the precipitate of cuprous iodide washed with cold water, and the cobalt and nickel determined in the filtrate. The copper may alternatively be removed as cuprous thiocyanate prior to the precipitation of the cobalt and nickel, and the filtrate oxidised with nitric acid, evaporated nearly to dryness, and treated with tartaric acid, ammonia, and potassium iodide. Cadmium yields a white crystalline precipitate of tetrammine cadmium iodide, $[\text{Cd}(\text{NH}_3)_4]\text{I}_2$, and is co-precipitated with nickel and cobalt. In the rare cases when it is present in nickel and cobalt ores it may be separated by passing a current of hydrogen sulphide through a solution of the mixed iodide precipitate, faintly acidified with sulphuric acid. Zinc is not precipitated under the conditions of the determination. Barium salts are removed from ores as sulphate at the same time as the insoluble gangue. Soluble calcium salts do not interfere with the method, but if present in large quantity they might crystallise as tartrate and interfere with the separation of the cobalt. In such cases it is advisable to evaporate the solution of the ore with 1 c.c. of strong sulphuric acid until fumes appear, then to add water and an equal volume of methylated spirit, and separate the anhydrous calcium sulphate. The precipitate is washed with 50% alcohol, and the filtrate and washings evaporated to about 5 c.c. Magnesium has no influence on the results. Lead iodide is soluble in ammoniacal tartrate solution and its presence is negligible, but if lead is present in large amount it may be separated as sulphate. Mercuric salts yield a complex iodide which crystallises in needles, and is decomposed by water and acids leaving insoluble mercuric iodide. Silver forms a white precipitate which is decomposed by water or dilute acids, yielding the normal iodide, which can be separated by filtration. Aluminium, chromium, antimony, and bismuth do not interfere with the determination provided that sufficient tartaric acid has been added. Arsenic, oxidised by nitric acid into arsenic acid, does not influence the results. Should arsenic and magnesium be present together (e.g., as in dolomite) a preliminary fusion of the ore with soda-sulphur or soda-nitre mixture would be necessary, since otherwise magnesium ammonium arsenate would be precipitated on the addition of tartaric acid and ammonia. Sulphides, unless decomposable by hydrochloric acid, are oxidised by nitric acid to sulphates, although in the separation of copper, as described above, some tetram-

mine cupric sulphate may be precipitated with the mixed iodide precipitate. This compound sulphate is converted into cuprous iodide when the mixed iodide precipitate is treated with hydrochloric acid, provided sufficient nickel or cobalt iodide is present; otherwise sufficient potassium iodide must be added to precipitate the whole of the copper. When an ore is treated with sulphuric acid as little as possible should be used, or most of the excess expelled as described in the case of calcium. Ammonium chloride in quantities exceeding 0.5 gm. has a slight solvent action upon the iodide precipitates, especially that of nickel. Hence if an ore has been decomposed with hydrochloric acid, the excess should be removed by boiling and the chlorides decomposed by evaporating the solution to a small volume with nitric acid, care being taken to avoid the separation of basic salts. The required amount of tartaric acid may then be added in the smallest quantity of hot water necessary to dissolve it, and the liquid cooled and treated with ammonia and potassium iodide.—C. A. M.

Lead ores; Treatment of low-grade —. A. E. Wells. U.S. Bureau of Mines, Salt Lake Expt. Sta. Rept.

LOW-GRADE lead ores which had failed to yield to flotation or leaching processes, were heated with sodium chloride to about 800° C.; high extractions of lead were obtained, irrespective of the type of gangue in the ore. The lead volatilises as chloride, and silver and gold are also volatilised. The chlorides are precipitated from the fume in a Cottrell precipitator. The lead chloride is mixed with lime and a small quantity of reducing agent, and submitted to a red heat; metallic lead and calcium chloride are obtained, and the latter can be used in place of sodium chloride in the first operation; from 50 to 75% of the chlorine is recovered in this manner. It is considered possible that the process will be cheaper than water concentration followed by smelting.

[*Flotation*.] *Process and apparatus for separating ores* [by —]. E. Primosigh, Also-Szalank, Hungary. Eng. Pat. 10,087 of 1914; date of appl., Dec. 19, 1913.

AN intermittent flotation process for finely-divided ores (—130 mesh) is carried out in an apparatus consisting of a closed mixing vat divided into compartments and containing mixers on horizontal shafts rotating in opposite directions. The material is thus circulated outwardly from the centre of the mixer and upwardly into a concentric inner chamber containing a hollow cone, through which the froth is allowed to rise by retarding the downward motion, with or without the aid of compressed air.—W. R. S.

Ore-flotation process and apparatus. H. C. Colburn, Colorado Springs, and E. A. Colburn, Denver, Colo. U.S. Pats. (A) 1,226,062 and (B) 1,226,063, May 15, 1917. Dates of appl., May 31 and Oct. 31, 1916.

(A) The process consists in mixing the ore pulp

with an oil, agitating and emulsifying the mixture in a receptacle with addition of a gas under reduced pressure, and causing the froth to rise in another receptacle under a higher pressure. (B) The apparatus comprises a mixing-chamber having a feed opening and air outlet, inlets for introducing oil and gas, a mixer for emulsifying the pulp, and means for maintaining a partial vacuum; and a settling chamber under a higher pressure, connected with the outlet of the mixing-chamber.—W. R. S.

Flotation; Process of concentrating and separating minerals by —. H. E. T. Haultain, Toronto, Canada. U.S. Pat. 1,226,330, May 15, 1917. Date of appl., June 15, 1915.

THE ore pulp is first treated by flotation in a series of steps in which the sinking products are successively re-treated to obtain a final sinking product free from the most readily floatable constituent. The floating products are again treated by flotation in a series of steps in which the floating products of each step except the first are returned for re-treatment in a previous step to obtain a clean final product as a float from the first step. The floating products of the first stage are introduced at different steps in the second stage, and those of the later steps are progressively moved up for re-treatment in earlier steps.—W. R. S.

Coating metal plates with tin, terne, or other metal or alloy. P. B. Taylor, Briton Ferry, S. Wales. Eng. Pat. 106,120, May 5, 1916. (Appl. No. 6501 of 1916.)

THE apparatus is provided at the entry end with a hood closed by the feed rolls in combination with a flap, so that the surface of an entering plate is kept in a moist atmosphere and in contact with flux fumes. The upper surface of the plates is kept damp and sprayed with a current of fumes from a jet device above the surface of the flux. In this manner a coating of equal brilliancy and finish is claimed to be obtained on both sides of coated plates.—W. R. S.

Electroplating non-conducting substances with copper; Process of —. H. Ueno, Tokyo, Japan. Eng. Pat. 106,181, July 29, 1916. (Appl. No. 10,228 of 1916.)

ARTICLES of wood, porcelain, cloth, plaster, etc., are impregnated with a mixture of beeswax, paraffin wax, and white wax; the surface is covered with a powder formed from a mixture of graphite (100 parts), mercury (2 parts), auric chloride (1 part), and sulphuric ether (50 parts), and the articles are then subjected to the action of an electric current in a solution of copper sulphate.—B. N.

Pickling-bath and method of making same. A. F. Hoffman, Assignor to W. M. Parkin, Pittsburgh, Pa. U.S. Pat. 1,225,956, May 15, 1915. Date of appl., July 21, 1915.

SULPHURIC acid is added to concentrated brine in the molecular proportion $H_2SO_4 : NaCl$. The precipitate formed in the presence of the material being pickled is removed and heated in order to produce gases which will combine with the residual liquor to produce pickling elements.—E. W. L.

Copper; Process for the extraction and recovery of —. A. Cox, Plainfield, N.J., and A. H. Peter, New York. U.S. Pat. 1,226,190, May 15, 1917. Date of appl., Aug. 20, 1913.

THE copper in the ore is converted into sulphide by treating it with a soluble sulphur-yielding

compound; the copper sulphide is extracted by cyanide solution, and the copper recovered from the liquor.—W. R. S.

Furnace for heating or annealing. *Furnace.* U.S. Pats. 1,226,266 and 1,226,267. See I.

XI.—ELECTRO-CHEMISTRY.

PATENTS.

Electrodes; Electric furnace — V. Stobie and S. Davenport, Dunston-on-Tyne, Durham, Eng. Pat. 106,152, May 22, 1916. (Appl. No. 7244 of 1916.)

STEEL or iron turnings are added to the usual substances used in the manufacture of carbon electrodes and electrode jointings for electric furnaces.—B. N.

Electrodes; Manufacture of ——. Electric furnace and method of producing molten magnetite therein. A. P. Scott, Chicago, Ill., Assignor to Chile Exploration Co., New York. U.S. Pats. (A) 1,226,121, and (B) 1,226,122, May 15, 1917. Date of appl., Nov. 17, 1915.

(A) HOLLOW electrodes are formed by pouring molten magnetite, at about 1590° C., into moulds heated to about 350° C., the moulds being provided with a heated removable top in the form of an extension. The mould is left undisturbed for about one minute, and the magnetite still remaining molten is then poured out, leaving a hollow electrode, which is stripped from the mould at about 1100° or 1200° C. It is annealed by immersion in a finely-divided material, for a sufficient length of time to permit the desired cooling to take place. (B) A single-phase, alternating-current electric furnace of the direct arc type is provided with a lower fixed contact, and an upper movable electrode. The bottom electrode is formed from a protective conducting layer of magnetite overlying the bottom contact, and cast magnetite scrap is incorporated with the magnetite layer.

—B. N.

Electric furnace. F. C. Schmitz, New York. U.S. Pat. 1,226,261, May 15, 1917. Date of appl., Nov. 3, 1913.

IS an electric furnace the melting pot is trough-shaped and is supported by a U-shaped beam at each end, and by longitudinal reinforced concrete beams with their ends on the U-beams and their outer flanges projecting beyond the walls. Removable water-cooled units are placed between the longitudinal beams and are supported by means resting on the exposed flanges of the beams. Similar parallel beams and water-cooled units are provided in the end walls of the pot.

XII.—FATS; OILS; WAXES.

Olive and other oils; Rapid method of obtaining neutral — suitable for the preparation of camphorated oil. G. Cordier and A. Lesure, J. Pharm. Chim., 1917, 15, 369—381.

To remove free fatty acids from olive oil intended for the preparation of camphorated oil for injection, the French Codex prescribes that the oil should be washed with alcohol, but the method is tedious and removes only part of the acidity. A much more rapid and effectual process is to neutralise the free fatty acids with alkali, in the presence of alcohol, which will dissolve nearly the whole of the resulting soap. The oil is freed from the last traces of alcohol by heating, and the soap dissolved in this alcohol is left completely insoluble in the oil, and may be separated by hot filtration.—C. A. M.

Peanut [arachis] oil; Detection of — in olive oil R. Land. Amer. Perfumer, 1917, 12, 89.

THE following modification of a method devised by Franz is recommended for the detection and approximate determination of arachis oil in olive oil:—One c.c. of the oil is saponified with 5 c.c. of 8% alcoholic potassium hydroxide solution (80 grms. of potassium hydroxide in 80 c.c. of water made up to 1 litre with 90% alcohol). The flask is fitted with a condensing tube 80 cm. long and is heated on the water-bath, with continuous shaking, until the oil is saponified (1 min.). The soap solution is cooled to 25° C. and treated with 1.5 c.c. of dilute acetic acid (1:2) and 5 c.c. of 70% alcohol. If the liquid becomes turbid, as is usually the case in the presence of much arachis oil, the flask is heated on the water-bath, until clear solution is obtained. It is then slowly cooled, and the temperature at which a flocculent deposit begins to form is noted. The crystallisation temperature for the alcoholic fatty mixture from pure olive oil usually falls between 13° and 11° C., but in exceptional cases may be somewhat lower. In the case of arachis oil the crystallisation temperature is about 40° to 41° C. Should the temperature fall to 15° C. without crystallisation taking place the quantity of arachis oil, if present at all, must be less than 5%. Franz gives the following crystallisation temperatures for mixtures of olive oil and arachis oil:—Pure olive oil, 13-5

with 5% arachis oil, 16.9°; with 10%, 19.8°; with 20%, 25.7°; with 30%, 29.2°; with 40%, 31.5°; with 50%, 33.8°; with 60%, 35.3°; with 70%, 36.6°; with 80%, 38.0°; with 90%, 39.3°; and pure arachis oil, 40.3° C. The formation of a deposit at 16° C. may be due to the presence of insufficient acetic acid, for, in exceptional cases, the potassium salts precipitate the myristic acid. Should such a precipitate be obtained an additional three drops of acetic acid is added, and the flask heated on the water-bath until a clear solution is obtained, which is then cooled as before.—C. A. M.

Perilla oil and pawlownia [tung or wood] oil in Japan. U.S. Cons. Rep. No. 105 of 1917.

THE average annual crop of perilla seed in Japan is approximately 1,000,000 kin (1,230,000 lb.); 1,283,662 U.S. gallons of perilla oil, worth \$691,742, and 930,436 gallons, valued at \$186,894, were produced in Japan in 1912 and 1913, respectively. An oil used in Japan in the manufacture of oil-paper and paints, and for illuminating purposes, is obtained from the fruit of a tree, *Aleurites cordata* ("oil pawlownia"). This tree had been growing wild in Japan until four years ago, when it was for the first time, on a very small scale, cultivated for commercial purposes. The use of the "oil pawlownia" product has been known in Japan for a long time, but has not yet acquired any commercial importance. The oil is extracted by the most primitive methods (drying, pounding, steaming, and crushing) by producers on their farms. Japan's output is about 1,500,000 bushels of nuts annually, from which 238,309 gallons of oil, worth \$110,000, is obtained. None of this oil is exported. Shells and kernels crushed together give 36.1% of oil, while 48.85% of oil is obtained from the kernel.

Unsaponifiable matter in oils, fats, and waxes; Determination of —. J. M. Wilkie. Analyst, 1917, 42, 200—202.

FIVE grms. of the oil, etc., is heated with 12.5 c.c. of 2N-alcoholic potassium hydroxide solution for $\frac{1}{2}$ to 1 hour in a flask beneath a reflux condenser, and is then transferred to a separating funnel with 50 c.c. of water and extracted with successive portions of 40, 30, and 30 c.c. of ether. The ethereal extracts are united in a separating funnel containing about 20 c.c. of water. The latter is run off without shaking, and the ethereal solution is washed with 2, 5, and 30 c.c. of water, and evaporated, and the residue weighed. In the case of sperm and similar oils a fourth extraction with 30 c.c. of ether is required. The difficulty of treating saponified beeswax with ether may be overcome by introducing the soaps of the fatty acids of ordinary oils, and especially those of linseed and castor oils, which have a solvent action upon hydrocarbons:—A mixture of 0.5 gm. of the beeswax with 4.5 grms. of castor oil is saponified with 12.5 c.c. of 2N-alcoholic potassium hydroxide solution for 1 hour, and the soap solution transferred to the separator with 40 c.c. of water at 30° C., and extracted with 50, 40, 40, and 30 c.c. of ether. The ethereal extracts are washed with 2, 5, and 30 c.c. of water and evaporated, and a deduction made from the residue for the known unsaponifiable matter in the castor oil. The results thus obtained agree well with those normally given by oils, fats, and waxes. In the case of medicinal cod liver oil the unsaponifiable matter is often distinctly crystalline.—C. A. M.

Oils; Rapid method of determining the suitability of — for soap-making. R. Lecoq. Bull. Soc. Chim., 1917, 21, 101—103.

A SMALL quantity of the oil may be converted

into a neutral soap by the action of the exact quantity of alkali indicated by the saponification value, provided that the following conditions are observed. A good emulsification, which is essential, can only be obtained with weak lyes (8° to 10° B., sp. gr. 1.059—1.074), but complete saponification cannot be effected by lyes weaker than this. To obtain good emulsification it is advisable to add the lye to the oil rather than the oil to the lye. The quantity of sodium chloride required for "salting out" a neutral soap varies with the nature of the soap, and the soaps will contain variable amounts of water. The addition of a special soap (10 grms. in 56 c.c. of water) to 100 grms. of the oil promotes rapid emulsification. The mixture is heated on the water-bath in a 750 c.c. conical flask the mouth of which is covered with a perforated watch-glass through which passes an agitator. The amount of alkali solution (in about 60 c.c.), calculated from the saponification value, is added at the rate of about 12 c.c. every 30 mins., and after boiling the mixture for $\frac{1}{2}$ hours saponification is complete. Potassium (soft) soaps thus prepared require dilution to bring them to the conventional standard of 50% of water. In the case of soda soaps the product is dissolved in 400 c.c. of water, and the soap precipitated by the addition of 125 grms. of salt, the liquid decanted, and the soap dried with the aid of a pump. Fatty acids are best saponified by adding them after melting, in two fractions (3 parts and 1 part), at an interval of 30 mins., to the whole of the hot alkali lye. Saponification is complete after boiling for 1 hour.—C. A. M.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Oleoresin of Douglas fir. A. W. Schorger, J. Amer. Chem. Soc., 1917, 39, 1010—1044.

THE author examined two authentic samples of oleoresin from the heartwood of Douglas fir, possessing the following constants:—Sp. gr. at 20° C., 0.993 and 0.989; $[\alpha]_D^{25} = +2.84$ (second sample only); acid value, 115.6 and 114.2; saponif. value, 121.7 and 120.5; volatile oil, 30.4 and 28.64%; colophony, 68.82 and 69.77%. The volatile oil was found to consist mainly of *l*- α -pinene (b. pt. 156°—157° C.; sp. gr. at 20° C., 0.859; refr. ind., $n_D^{20} = 1.4670$; $[\alpha]_D^{25} = -47.52$) together with smaller quantities of *l*-limonene and *l*-terpineol. The *l*- α -pinene yielded pinonic acid on oxidation, but, as was anticipated from its high rotatory power, it formed no nitroschloride. It is doubtless identical with the "terpene" of Frankforter and Frary (this J., 1906, 1107). A sample of oleoresin from the sapwood of Douglas fir yielded 22% of volatile oil containing *l*- α -pinene (b. pt. 156°—158° C.; sp. gr. at 15° C., 0.8629; $[\alpha]_D^{25} = -18.96$; nitroschloride, m. pt. 103° C.) besides *l*- β -pinene and probably *l*-limonene.—J. H. L.

PATENTS.

Ink [; Printing —] and process of making the same. A. Rogers, Brooklyn, N.Y. U.S. Pat. 1,224,668, May 1, 1917. Date of appl., Feb. 1, 1917.

A NEWSPAPER ink is prepared by mixing 39% of a thickened odourless, asphalt-base petroleum residue, with about 47% of oil of 43° B. (sp. gr. 0.824) known as "300" oil," about 4% of rosin, 0.25% of chip soap, and 10% of carbon black; or the petroleum residue may be heated until it is odourless and has a density of about 14.5° B. (0.909), and is then mixed with about two-thirds of its vol. of "300" oil," about 5% of rosin, 12% of carbon black, and 0.25% of soap.—C. A. M.

Condensation product, and process of making same. Synthetic gum. Artificial gum and process of making same. (A) W. A. Beatty, Assignor to G. W. Beadle; (B) and (C) W. A. Beatty, New York. U.S. Pats. (A) 1,225,748, (B) 1,225,749, and (C) 1,225,750, May 15, 1917. Dates of appl., (A) June 6, 1912; (B) and (C) June 30, 1915.

(A) A CONDENSATION product, consisting of a brittle, odourless gum which is soluble in alkalis, acetone, alcohol, amyl alcohol, amyl acetate, glacial acetic acid, and tetrachloroethane; insoluble in linseed oil, turpentine, and mineral oils; converted into a substance insoluble in alkalis by the action of an acid; and by heat into a substance insoluble in the above-named solvents, is obtained by condensing a substance having the formula $R_2C(C_6H_4OH)_2$ —where R is an alkyl group—with a substance containing at least one methylene group. (B) The condensation product obtained by heating $R_2C(C_6H_4OH)_2$ —where R is an alkyl group—with a substance containing at least one active methylene group, in presence of alkali at 100°—150° C., is further heated, when a hard, inodorous, transparent, non-brittle and not easily inflammable substance, insoluble, and unacted upon by acids, alkalis, acetone, alcohol, amyl alcohol, amyl acetate, glacial acetic acid, tetrachloroethane, or mixtures of these, is produced. (C) A gum, soluble in alcohol and alkali, and convertible into an insoluble mass, is obtained by condensing a ketone, such as acetone, or an impure ketone, with a cresol, or mixture of cresols, or an impure phenol containing cresol, and condensing the resulting product with an aldehyde, such as formaldehyde. (See also Fr. Pat. 447,647 of 1912; this J., 1913, 244.)—E. W. L.

Floor covering. D. F. Haverstick, Trenton, N.J. U.S. Pat. 1,225,954, May 15, 1917. Date of appl., May 17, 1916.

THE floor covering consists of a backing of suitable fibrous sheet material saturated with a water-proofing substance, covered by an impervious layer of Manila copal, or a mixture of the latte and acaroid resin; and a top or surface layer of flexible material.—E. W. L.

Paint and process of making same. J. Jacob, Maastricht, Netherlands. U.S. Pat. 1,226,888, May 22, 1917. Date of appl., Mar. 7, 1916.

SEE Eng. Pat. 16,448 of 1915; this J., 1916, 933.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Caoutchouc or its homologues: Polymerisation isoprene, divinyl, and dimethylerythrene to — I. Ostromyslenski. J. Russ. Phys.-Chem. So. 1916, 48, 1071—1114.

THE author has investigated the different caoutchoucs obtained by polymerisation from (1) mixtures of isoprene with amylenes, (2) isoprene, (3) mixtures of erythrene with butylenes, (4) erythrene, and (5) $\beta\gamma$ -dimethylethyrene. The determination of the physical properties of different caoutchoucs and that of the two new constants (this J., 1916, 58) renders it necessary to modify the views formerly held with respect to their constitution and the author now considers that higher and lower caoutchouc-like polymerides of one and the same diolefin do not exist, but that the various isomeric caoutchoucs are polymerides of one and the same magnitude. Thus, the isomerism of "individual" caoutchoucs is determined.

mined solely by the positions of the ethylene linkages of the nucleus or by the positions of the methyl groups in the side chains.

The four isoprene-caoutchoucs described below are obtained under conditions of catalytic thermopolymerisation which when applied to erythrene yield always one and the same caoutchouc. In erythrene-caoutchouc, as in erythrene, there are no methyl groups but the number of double linkages present is the same as in isoprene-caoutchouc. Consequently, the isomerism of α -, β -, γ - and δ -isoprene-caoutchoucs is conditioned by differences in the positions of the methyl groups, i.e., of the side chains.

The same conclusion may be drawn from the existence of only one form of $\beta\gamma$ -dimethylethyrene-caoutchouc. The two methyl groups of $\beta\gamma$ -dimethylethyrene are arranged symmetrically in the molecule and thus, unlike the single methyl group of isoprene, cannot give rise to isomerides. The isomerism of normal γ -isoprene-caoutchouc with normal ϵ -caoutchouc is, however, probably conditioned by the different positions occupied by their ethylene linkages, since the conditions in which isomerides are formed are those in which the corresponding isomerides of erythrene-caoutchouc are obtained.

Two abnormal isoprene-amylene-caoutchoucs are described: (1) the α -form, obtained first by Matthews and Strange, and later, under the name of sodium-isoprene-caoutchouc, by Haries; (2) the β -isomeride, here described for the first time and prepared in quantitative yield by the catalytic action of barium peroxide or benzoyl peroxide on the α -form in toluene solution. α -Isoprene-amylene-caoutchouc forms a viscous sticky mass which adheres firmly to wood, metal, glass, etc., and is easily drawn out into long threads; when exposed to the air it becomes covered with an oxidised layer which is non-adhesive. When vulcanised it yields a product which is not sticky or plastic but is also devoid of the elastic properties of natural caoutchouc and may be easily torn like a rotten rag; its elastic point evidently lies above its temperature of decomposition. This caoutchouc has no industrial application and when added to natural caoutchouc, even to the extent of 1%, appreciably lowers the value. The molecule of α -isoprene-amylene-caoutchouc probably contains the amylene as a saturated radicle, $-\text{C}(\text{CH}_3)_2\text{CH}(\text{CH}_3)-$ the proportion of bromine combined diminishing as that of the amylene mixed with the isoprene increases. The structure may be represented thus:—

That amylene is present in the molecule is supported by the gradual and direct alteration of the physical properties as the proportion of amylene used increases; for example, the liquid state is more and more nearly approached. Elementary analysis is insufficient to detect the presence of even considerable proportions of amylene. If, in the preparation of α -isoprene-amylene-caoutchouc, the amylene is replaced by isobutylene, caoutchoucs with similar properties are obtained.

β -Isoprene-amylene-caoutchouc forms a compact mass quite free from pastiness and at about 100° C. acquires all the elastic properties of natural caoutchouc, its elasticity point being thus lower than that of the α -isomeride. In the air β -isoprene-amylene-caoutchouc is oxidised moderately rapidly to a very compact, solid, amorphous, oxygenated mass, which can be readily pounded to a fine powder; as the oxidation proceeds the elasticity point and the "fatal temperature" gradually rise. Vulcanisation converts it into a product which at 80°–90° C. exhibits all the properties of vulcanised natural caoutchouc.

α -Isoprene-caoutchouc, prepared by the action

of sodium on chemically pure isoprene at 60°–75° C. for 10–11 hours, differs considerably from α -isoprene-amylene-caoutchouc, which is obtained from isoprene containing amylene, in particular from the isoprene prepared by the catalytic removal of two molecules of hydrogen chloride from dichloro-isopentane at a low pressure: α -isoprene-caoutchouc forms a colourless, glass-transparent non-glutinous, non-fluid, insoluble mass, which can be rolled hot or easily broken, but not drawn into threads; it swells up slowly and slightly in various media but does not dissolve even in traces. Its elasticity is low and the noise of its impact resembles that of a solid body. It is an abnormal caoutchouc, its elasticity point lying above 110° C. and its "fatal temperature" somewhat below 0° C.; at about 110° C. it acquires all the elastic properties of natural caoutchouc. It is vulcanised by sulphur or nitro-compounds, although more slowly than caoutchoucs of the normal series, and it is applicable in practice only for certain special purposes. β -Isoprene-caoutchouc, obtained in quantitative yield by the action of a mixture of sodium with barium (or benzoyl) peroxide on pure isoprene at 60°–70° C., has usually a pale cinnamon colour and is transparent in thin layers; it flakes but has no stickiness or fluidity and may be rolled comparatively easily even at 60° C. It is an abnormal caoutchouc, its elasticity point being about 80°–90° C., which is somewhat lower than that of the α -isomeride, and its "fatal temperature" about –10° C.

γ -Isoprene-caoutchouc, prepared in small yield (40%) by the action of barium or benzoyl peroxide or an alkali sulphide or polysulphide on chemically pure isoprene at 45°–50° C. for 2–4 months, is an almost colourless, glass-transparent, brittle, amorphous substance, which cannot be drawn into threads but is possessed of considerable elasticity and spring; after deformation it resumes its original form and dimensions almost instantaneously. It is a normal caoutchouc, its elasticity point and "fatal temperature" being about the same as those of natural caoutchouc.

α -Isoprene-caoutchouc, prepared from β -myrcene, is of the normal series.

ϵ -Isoprene-caoutchouc is the name proposed by the author for the caoutchouc obtained in quantitative yield by gently heating isoprene with sodium in an atmosphere of carbon dioxide. It is formed also by the action of ultra-violet light on isoprene in presence of sodium and carbon dioxide. It is a normal isoprene-caoutchouc and quite insoluble. This form appears to be a physical isomeride of the normal γ -isoprene-caoutchouc, the elasticity points and the "fatal temperatures" being apparently the same for the two. Towards a mixture of sodium and carbon bisulphide isoprene is quite passive, both at the ordinary temperature and on heating.

Recovered caoutchouc is always abnormal, its "fatal temperature" and elasticity point being relatively high; only above 120° C. does it regain the elastic properties of ordinary caoutchouc. The process of recovery is evidently accompanied by rearrangement in the nucleus.

α -Erythrene-caoutchouc is obtained by heating erythrene alone or with sodium (0.3–0.5%), barium peroxide, sodium and barium peroxide, or first with one of these and then with the other. When, however, the erythrene is heated in presence of sodium and in an atmosphere of carbon dioxide, it is converted into an insoluble ϵ -caoutchouc analogous to the normal insoluble ϵ -isoprene-caoutchouc. The isomerism appears to be of a chemical character and conditioned only by the different positions of the ethylene linkages in the molecule. A third isomeride (α') is often formed in small proportion, together with the α -variety, when erythrene is heated with sodium in absence

of carbon dioxide. This differs from α -erythrene-caoutchouc only in its insolubility and is a highly elastic, colourless, glass-transparent substance, which swells in light petroleum, turpentine, etc., and is readily vulcanised under the ordinary conditions given for the vulcanisation of synthetic caoutchoucs.

α -Erythrene-caoutchouc is a colourless, transparent, elastic, highly resilient, non-adhesive substance, which is readily rolled in the hot, but if rolled in the cold requires slight admixture of a liquid of high boiling point, since otherwise it crumbles between the rolls like factis; after deformation, if not too prolonged, it recovers its form and dimensions almost instantly. This caoutchouc belongs to the normal series, its elasticity point and "fatal temperature" being somewhat lower than those of Para caoutchouc; thus, at normal temperatures it is more elastic than natural caoutchouc, and it remains elastic when Para rubber reaches its elasticity point. It is vulcanised more rapidly and easily than the natural rubber under ordinary conditions or by means of benzoyl peroxide, nitro-compounds, chlorine, etc. The vulcanised product is highly elastic and resilient and its residual elongation negligible; it is more resistant to deformation than vulcanised natural caoutchouc, but its resistance to shearing is slight. If, before vulcanisation, the caoutchouc is caused to swell by means of albumin or some other substance with colloidal properties, the resulting product corresponds in properties with vulcanised natural caoutchouc.

α -Erythrene-butylene-caoutchouc, prepared by the action of sodium on erythrene containing butylene, closely resembles α -isoprene-amylene-caoutchouc.

β -Erythrene-butylene-caoutchouc, prepared by heating a toluene solution of the α -isomeride with barium peroxide (0.5—5%) at 60°—75° C. for 1—7 days, is not sticky, very compact, somewhat resistant to shearing, cannot be drawn into threads, and is moderately easily rolled in the cold. It belongs to the normal series and is readily vulcanised to a product showing all the properties of vulcanised natural caoutchouc; it dissolves in benzene, light petroleum, turpentine, etc. The isomerisation of the α - to the β -isomeride occurs only if the former contains comparatively little butylene, erythrene containing 10—15% of the latter being utilisable.

All the caoutchoucs which have been obtained from $\beta\gamma$ -dimethylethythrene (Concunier, Ann. Chim. Phys., 1892, [vi.], 26, 489; Kondakoff, J. prakt. Chem., 1901, [ii.], 64, 109; Harries, this J., 1911, 1973) have been investigated and are found to be identical; they usually contain varying proportions of the dimeride and of foreign liquids, which lower the elasticity point and the "fatal temperature." The form obtained by the action of sunlight on the monomeride (α') does, indeed, differ from that resulting from the thermo-polymerisation of $\beta\gamma$ -dimethylethythrene (α) by its solubility in various media, but this difference is doubtless conditioned by differences in the physical state, the two being merely colloidal modifications of one and the same hydrocarbon. A number of different catalysts were employed, but in all cases the α -form was obtained in the hot and mostly the α' -form at temperatures up to 20°—30° C. Further, polymerisation of $\beta\gamma$ -dimethylethythrene in presence of foreign olefins yields always the ordinary α - or α' -modification, mixed or "combined" forms not being obtained in this case. The α -form of $\beta\gamma$ -dimethylethythrene-caoutchouc, obtained at any temperature from 40° to 170° C. and especially rapidly in presence of a small proportion (1%) of piperidine piperidylthiocarbamate, belongs to the abnormal series, its elasticity point being 125°—130° C. and its

"fatal temperature" -5° C. When vulcanised it acquires all the elastic properties of natural caoutchouc at 109° C.—T. H. P.

Erythrene-caoutchouc: Synthesis of the symmetrical and higher chlorides of—. New chlorides of natural, isoprene- and erythrene-caoutchoucs. I. Ostromyslenski. J. Russ. Phys.-Chem. Soc., 1916, 48, 1132—1151.

It has been already shown that polymerised vinyl bromide represents the symmetrical bromide of erythrene-caoutchouc and the natural supposition that caouprene chloride is the corresponding symmetrical chloride is now justified experimentally. Baumann (Annalen, 1872, 163, 317) described caouprene chloride as a viscous, plastic, insoluble mass, but these properties are caused by admixture of extraneous liquids such as the higher chloro-derivatives of ethane, esters of the fatty acids, etc., the chemically pure chloride being a snow-white, amorphous mass readily reducible to a fine powder. Caouprene chloride is rapidly formed by the action of the light from a quartz mercury lamp on liquid vinyl chloride and exists in a soluble α -modification, which swells in various media to a more or less mobile layer, and in a more stable, insoluble γ -form; the former is completely converted into the latter by prolonged heating at 30°—40° C. or by the action of the light from a mercury lamp. The relation between the α - and γ -caouprene chlorides is undoubtedly analogous to that between the α - and α' -forms of $\beta\gamma$ -dimethylethythrene-caoutchouc (see preceding abstract). The asymmetric chlorides of erythrene-caoutchouc and natural caoutchouc also exist in a soluble α - and an insoluble γ -modification. The molecular weight of α -caouprene chloride, measured cryoscopically in ethylene bromide solution, is 1021, which corresponds with the molecule $(\text{CH}_2\text{CHCl})_{16} = 999$; this result is in agreement with that obtained for caouprene bromide. When heated with one of a number of different compounds, α - and γ -caouprene chlorides give ebonite-like substances which are identical with those obtained under analogous conditions from the asymmetric chloride of erythrene-caoutchouc (see following abstract) and in their physical and mechanical properties closely resemble the ebonites obtained from the chloride of natural Para caoutchouc.

Like the bromide, caouprene chloride is a unicyclic halogenide, the ring containing sixteen CHCl-CH_2 groups. The absence of double linkages is shown by its behaviour towards various reagents, such as permanganate, tetranitromethane, etc., and especially by its stability towards oxidising agents like chromic acid and concentrated nitric acid (sp. gr. 1.35), by its passivity towards halogen hydracids, including boiling hydrochloric acid, and towards concentrated sulphuric acid, and by the ability of the halogen present to take part in reactions of double decomposition.

Unlike all natural and synthetic caoutchoucs and all their known halogenated derivatives, which are insoluble in acetone, α -caouprene chloride dissolves readily in this solvent. Gradual addition of a solution of the calculated amount of chlorine in carbon tetrachloride to a solution of erythrene-caoutchouc in the same solvent yields an asymmetric chloride of erythrene-caoutchouc, $\text{C}_{32}\text{H}_{48}\text{Cl}_{16}$, isomeric with caouprene chloride, from which it differs only in the positions of the halogen atoms; this chloride also dissolves readily in acetone. Under the same conditions, natural caoutchouc gives a chloride of normal composition, $\text{C}_{32}\text{H}_{40}(\text{CH}_3)_8\text{Cl}_{18}$, also readily soluble in acetone. Like caouprene chloride, each of these chlorides exists in α - and γ -modifications. Owing to the solubility of the chlorides in acetone, they may be freed from admixtures of free caoutchouc

and of colloidal higher chloride and thus obtained in a chemically pure condition.

The polymeride of dichloroethylene yields a peculiar ebonite and is termed, by analogy, chlorocauprene chloride. It is isomeric with the higher chlorides of erythrene-caoutchouc, obtained by the action of chlorine on a solution of the free caoutchouc, the isomerism depending on the position of the halogen. Under the influence of the light of a quartz mercury lamp, asymmetric dichloroethylene polymerises almost instantly.

Cauprene chloride has been prepared from alcohol and chlorine by the following reactions: (1) $C_2H_5OH = C_2H_4 + H_2O$, (2) $C_2H_4 + Cl_2 = C_2H_4Cl_2$, (3) $C_2H_4Cl_2 + NaOH = NaCl + H_2O + CH_2 : CHCl$ and (4) $16(CH_2 : CHCl)_{16}$. Owing to the "poisoning" of the alumina used as catalyst in the dehydration of the alcohol, the yield of ethylene obtained gradually falls. It is found that this alumina may be regenerated by cautious ignition in a current of air and subsequent treatment with superheated steam. The yield of ebonite obtained amounts to at least 60–75 parts per 100 parts of absolute alcohol and this is probably capable of considerable increase by varying the experimental conditions employed. Pure vinyl chloride has b.pt. $-12^\circ C.$ and not $-18^\circ C.$ as stated in the literature.

The asymmetric chloride of erythrene-caoutchouc, $C_{32}H_{48}Cl_{16}$ (see above), is a snow-white, amorphous mass, which is readily powdered and becomes electrified when sifted through silk; it cannot be distinguished from cauprene chloride. It behaves towards permanganate like a saturated compound, remains colourless when treated with tetranitromethane, reacts with phenol losing hydrogen chloride, and is passive towards nitric acid (sp. gr. 1.35), concentrated sulphuric acid, boiling fuming hydrochloric acid (sp. gr. 1.19), and boiling chromic acid. Under similar conditions this chloride and cauprene chloride yield one and the same ebonite or one and the same plastic mass resembling celluloid or guttapercha (see following abstract); the two substances behave similarly towards camphor, naphthalene, copper oleate, etc., and are soluble in the same solvents.

The chloride of natural Para caoutchouc cannot be distinguished from that of synthetic normal γ -isoprene-caoutchouc, although they undoubtedly differ in the positions of the methyl groups in the nucleus. They are almost white, amorphous substances, which become electrified when rubbed and, when pure, are easily powdered. Chemically and physically they behave like homologues of the chlorides of erythrene-caoutchouc.

When treated in light petroleum (b.pt. up to $80^\circ C.$) solution with a current of anhydrous chlorine at $0^\circ C.$, α -erythrene-caoutchouc yields a higher chloride, $C_{32}H_{32}Cl_{32}$, which is white, amorphous, and opaque and may be readily crushed.—T. H. P.

Ebonite, celluloid, or guttapercha; Preparation of substances equivalent to—. *Synthesis of vulcanised caoutchouc.* I. Ostromyslenski. J. Russ. Phys.-Chem. Soc., 1916, 48, 1114–1131.

WHEN treated with free chlorine, either natural or synthetic caoutchouc is converted into a substance which exhibits the properties of ebonite, in some cases to an enhanced degree. In its stability towards alkali or high temperatures it is the equal of ebonite and, unlike the latter, it is very stable towards acids. Thus, the product obtained by the action of chlorine on synthetic normal erythrene-caoutchouc is not changed by the prolonged action of nitric acid (sp. gr. 1.35), by boiling fuming hydrochloric acid (sp. gr. 1.19), by boiling chromic acid, or concentrated sulphuric acid. It may be worked and polished like the

best ebonite obtained from caoutchouc and sulphur and is equally plastic. Its specific gravity is almost equal to that of ebonite, and it is a better electrical insulator, its conductivity approximating to that of the best types of glass and bakelite. Ordinarily it is black but if prepared under certain special conditions it may be obtained almost white or even colourless and transparent and it is easily coloured. An ebonite-like substance may also be obtained by heating caoutchouc chloride or bromide (this J., 1916, 370) in an iron mould out of contact with air at the ordinary temperature employed in vulcanising caoutchouc, but the product yielded in this way is always more or less porous.

Cauprene chloride, readily obtainable either from ordinary alcohol and salt through mono- or di-chloroethane, or from carbon, lime, and hydrochloric acid through the carbide, may be easily converted into a plastic mass equivalent in its properties to celluloid, guttapercha, or the best ebonite. When treated with a very small proportion of naphthalene or copper oleate, the chloride yields a highly coherent ebonite; with camphor, paraffin wax, or hexachloroethane, a product corresponding with celluloid is obtained, whilst with oils such as paraffin oil, esters, tri-, tetra- or penta-chloroethane, or with a large excess of naphthalene, etc., a substance with all the properties of natural guttapercha is formed. This synthetic ebonite exhibits all the mechanical properties of ordinary ebonite and is furthermore non-inflammable and of high stability towards acids or an atmosphere of moist chlorine. Analogous products are obtainable in a similar manner from the higher chloride of caoutchouc, $C_{40}H_{48}Cl_{32}$, or the homologous chlorocauprene chloride.

—T. H. P.

Rubber plant, rich in rubber, indigenous to Germany. J. Schiller. Gummi-Zeit., 1916, 30, 499–510. Chem.-Zeit., 1917, 41, Rep., 156.

Lactuca viminea (N. O. *Compositae*) occurs in the western districts of the Danube valley and in the Elbe valley to beyond Dresden. It contains pure caoutchouc amounting to 0.49% of the dried plant, 19.06% of the total extractable substances, and 73.21% of the crude rubber. "Wolf's milk" (spurge) contains only 0.27%, "sow thistle" (*Sonchus oleraceus*) 0.16%, *Hevea Braziliensis* and *Kickxia elastica* 0.3%, and guayule (*Parthenium argentatum*) 10% of pure caoutchouc, calculated on the dry weight of the plant.—E. W. L.

XV.—LEATHER; BONE; HORN; GLUE.

Hide; Solubility of— in salt solutions. L. Balderston. J. Amer. Leather Chem. Assoc., 1917, 12, 193–198.

WET-SALTED hide, which has been soaked to remove salt and loose nitrogenous matter, appears to be no more soluble in dilute salt solutions than in water. A 20% salt solution exerts a marked preservative effect.—F. C. T.

PATENTS.

Leather, imitation; Methods and apparatus for making—. A. E. Alexander, London. From The Duratex Co., Newark, N.J., U.S.A. Eng. Pat. 106,336, May 22, 1916. (Appl. No. 7261 of 1916.)

SEE U.S. Pat. 1,190,806 of 1916; this J., 1916, 935. After being coated with the mixture containing nitrated cotton and oil, the fabric is subjected to

a calendering operation before the japanning composition is applied. An apparatus for carrying out the process is also claimed.

Glue joints: Method of waterproofing ——. F. H. Stevens, Horley, Surrey. Eng. Pat. 106,139. Jan. 9, 1917. (Appl. No. 132 of 1917.)

THE surfaces to be joined are moistened with a formaldehyde solution, preferably one containing 25% of a 10% aqueous solution, and are then covered with glue in the usual way. Formaldehyde may be added to the glue itself if the latter be used immediately after the addition.

—C. A. M.

Plastic material [from gelatin]; Process for the manufacture of a non-inflammable and odourless —, and the product thereof. R. Pioget; Paris. Eng. Pat. 106,118. Feb. 10, 1917. (Appl. No. 2047 of 1917.)

MELTED gelatin is treated with a solution containing a decoction of hops and dilute oxalic acid or other dicarboxylic acid of the general formula $C_nH_{2n-2}O_4$, whereby impurities are precipitated and the gelatin is rendered more supple. The liquid gelatin is formed into sticks or sheets, which are dried and coloured, and immersed in a bath containing formaldehyde (25 to 35%), water (25 to 35%), and alcohol (25 to 35%), together with oxalic acid or other dicarboxylic acid, as above, tannin, and glycerin. After impregnation, the sheets, etc., are dried, preferably in hot air, and form a plastic, malleable material, imitating ivory, horn, tortoiseshell, amber, etc., according to the colouring.—C. A. M.

XVI.—SOILS; FERTILISERS.

Soils: Fixation of ammonia in ——. I. G. McBeth. J. Agric. Res., 1917, 9, 141—155.

FIFTY mgrms. of nitrogen as ammonia or ammonium sulphate, chloride, or nitrate, was added to 100-grm. portions of a soil from Riverside, California, and after standing for 30 minutes, the portions were extracted with water, and with hydrochloric acid of concentrations varying from 1 to 10%. The amounts of ammonia in the extracts were then determined by distillation with sodium hydroxide. Determinations of ammonia were also made by direct distillation of the soil with magnesia. The amounts of ammonia found were practically the same for all the compounds used, water extracting about 25% and 10% acid about 52% of the added nitrogen. The nitrogen recovered by the same acid from a Lordsburg soil after similar treatment was also found to be independent of the nature of the anion of the ammonium salt, but the quantity was much less than from the Riverside soil (20% as against 52%). In both cases the magnesia method gave approximately the same figures as the 10% acid extraction method. Boiling the treated soils with sodium or potassium hydroxide solutions resulted in a much greater nitrogen recovery, 2.5 c.c. of the alkali giving the maximum amount (about 65%); and these results seem to hold for semi-arid soils and sub-soils generally. When 100-grm. samples of the two soils containing 50 mgrms. of ammonium sulphate were leached with water until 2400 c.c. of percolate was obtained, it was found that 33% of the added element was removed from the Riverside soil and 14.2% from the Lordsburg soil; 10% hydrochloric acid removed 81.2% from the former soil. The sub-soil of six out of seven semi-arid soils investigated showed an increased

nitrogen fixation with depth, and the fixation was greater the higher the concentration of the applied ammonium salt solution. Increase of temperature diminished the fixation, the amount of nitrogen recovered at 100° C. being only 53.6% of that recovered at 5° C. Fixation was most rapid during the first few minutes, but it continued for several days. When the soils were heated to temperatures not above 200° C. for six hours prior to the addition of the ammonium salt, the percentage recovery was unaffected, but at 250°—300° C. the recovery was much increased. The percentage of nitrogen fixed was nearly constant for small amounts of added ammonium sulphate, but beyond a certain point the percentage decreased, although the absolute amount continued to increase. The ammonia-fixing powers of the two semi-arid soils were reduced by the presence of salts of aluminium, iron, and potassium, but salts of calcium, magnesium, and sodium had practically no effect. The nature of the anion of the added salt was without influence. The amount of calcium brought into solution by ammonium chloride increased with the depth of the soil, but when the chlorides of aluminium, sodium, and magnesium were used as extracting media, the amount of calcium dissolved did not increase with the depth.—E. H. T.

Phosphoric acid in soils: Influence of the presence of calcium carbonate on the determination of available — by Dyer's method. J. N. Sen. Agr. J. India, 1917, 12, 258—265.

THE highly calcareous soils of Bihar, India, when examined by Dyer's method (extraction with 1% citric acid solution), are found to be poor in "available" phosphoric acid. The low results obtained are probably due to the interfering action of calcium carbonate, since the addition of 10% of calcium carbonate to a soil decreased the amount of "available" phosphoric acid from 0.312 to 0.009%. The action of calcium carbonate seems to reach a limit when the quantity added is increased to 20%, larger quantities causing no further diminution of the solvent action. The influence of calcium carbonate is, therefore, not due solely to neutralisation of the citric acid.

—W. P. S.

Lemna minor: Some effects of organic growth promoting substances (auxinones) on the growth of — in mineral culture solutions. W. I. Bottomley. Roy. Soc. Proc., 1917, 89 B, 481—507.

Lemna minor plants were cultivated in dishes of similar size, some of which contained only Detmer's solution, whilst others contained the same quantities of the mineral solution, with the addition of the decomposed phosphotungstic acid fraction or of the silver-baryta fraction, or other fractions of bacterised peat (this J., 1917, 975). It was found that the plants could not grow for any length of time in the solutions containing only mineral substances, and that the presence of soluble organic matter was essential. In addition to the culture solution 368 parts per million of organic matter from the aqueous extract of bacterised peat, the growth of the plants as compared with the control plants was increased 20 times in number and 62 times in weight. The aqueous extract freed from humic acid (corresponding to an addition of 97 parts of organic matter per million) caused the plants to increase 9½ times in number and 29 times in weight; the alcoholic extract (32 parts of organic matter per million) increased the growth by 3½ times the number and 7½ times the weight; and the phosphotungstic acid fraction (13 parts per million) gave 1½ times

the number and $2\frac{1}{2}$ times the weight. The progressive improvement in the appearance of the plants supplied with increasing amounts of auximones was also pronounced. The fact that comparable results were obtained in experiments in which "conductivity" or glass-distilled water was used proved that the beneficial effects of the auximones was not attributable to their neutralising toxic substances in the ordinary metal-distilled water. It is suggested that some of these growth-promoting substances may act directly as nutrients, whilst others act as accessory food materials. (See also this J., 1913, 878, 919, 920; 1914, 366; 1915, 881; 1916, 871).

—C. A. M.

Soil organisms concerned in the nitrogen cycle; Some effects of organic growth-promoting substances (auximones) on —. F. A. Mockeridge. Roy. Soc. Proc., 1917, 89 B, 508—533.

PURE cultures of *Azotobacter chroococcum* from the soil, and of *B. radicola*, the nitrogen-fixing organism of the nodules of leguminous plants, were cultivated in nutrient solutions to which were added small amounts of the different fractions of bacterised peat prepared as described by Bottomley (this J., 1914, 975). It was found that certain organic substances of unknown nature which could be separated from the prepared peat had an appreciable effect upon the rate of nitrogen fixation by these organisms. Similar experiments with nitrifying organisms in soil and in culture solutions showed that the addition of bacterised peat to a fertile soil caused a rapid increase in the proportion of nitrate up to a maximum, above which the growth of the organisms was inhibited by the concentration of the nitrate, and nitrification ceased. The rate of nitrification was greater in soil containing bacterised peat than in that containing an equivalent quantity of soluble ammonia in a form suitable for nitrification. The stimulation of the soil organisms does not depend upon the amount of nitrogen in the bacterised peat, judging by the effect of the phosphotungstic fraction upon the nitrification. It is probable, however, that the methods so far employed do not extract the whole of the auximones from the material. Although the auximone fractions accelerate the rate of nitrification both in soil and in culture solutions they have no influence upon the rate of ammonia formation. On the other hand, they reduce the rate of denitrification whether added to a pure culture of denitrifying organisms or to the soil itself. For example, whilst the amount of gas liberated in 48 hours by the soil alone was 63.0 c.c., that liberated by the same amount of soil to which the phosphotungstic fraction of bacterised peat had been added was only 8.1 c.c. The addition of an aqueous extract of the bacterised peat, however, has practically no effect upon denitrification, and it is suggested that this may be due to the depressing effect of the auximones being counterbalanced by the readily-oxidisable organic matter contained in the soil.

—C. A. M.

Plant growth; Accessory factors for —. O. Rosenheim. Biochem. J., 1917, 11, 7—10.

ACCORDING to Bottomley's experiments, peat rotted by aerobic soil organisms, then sterilised, and inoculated with nitrogen-fixing bacteria, was found to produce striking results in the development of pot-grown plants; later it was established that the presence of nitrogen-fixing bacteria was not an essential factor. The author has investigated the chemical composition of the soluble portion of the treated peat:—15 grms. of the substance was

steeped for 18 hours in 2 litres of water; 500 c.c. of the clear brown solution was decanted off and diluted to 1250 c.c. This extract contained 0.045% of total solids, 0.031 of organic substances, 0.011% of inorganic substances, and 0.005% of nitrogen. Plants of *Primula* grown in pots and treated with 60 c.c. of this extract showed a remarkable development of growth as compared with control plants, and it was found that treatment with a further 60 c.c. had no additional influence. It is to be noted that the quantity of plant food contained in 60 c.c. of the dilute extract is so infinitesimal that the results cannot be attributed to a direct nutrient action; an analogy is therefore suggested to the effects produced on animal growth by small quantities of accessory food substances termed "vitamines." Some of these latter are soluble in alcohol and are precipitated by phosphotungstic acid. Extracts were made under comparative conditions from garden soil, natural peat, and treated peat, using 15 grms. of material in 100 c.c. of water. To 20 c.c. of each filtrate was added 2.5 c.c. of concentrated sulphuric acid in 10 c.c. of water; the volume was made up to 50 c.c. and each extract treated with 30% phosphotungstic acid solution. The extract from the treated peat gave an immediate copious precipitate, that from natural peat only a faint opalescence, and that from garden soil remained clear. Extracts of treated peat made with alcohol or acetone, evaporated, and redissolved in water, also gave a heavy precipitate with phosphotungstic acid; a considerable part of the phosphotungstic acid precipitate was insoluble in acetone. The chemical examination of the treated peat extract lends strong support to the "vitamine" analogy deduced from the experiments on plant growth which should serve as a working hypothesis for future investigations.

—J. F. B.

Soil nitrogen; Relation of the transformation and distribution of — to the nutrition of citrus plants. I. G. McBeth. J. Agric. Res., 1917, 9, 183—251.

REPRESENTATIVE samples of soils to which nitrogenous materials were to be added were taken from each plot by means of borings to a depth of 12 in., and these were mixed, sifted, and kept in closed vessels. The desired quantity of the substance was then added to 1 kilo. of the dry soil, the moisture content brought up to the optimum, and incubation carried out in Mason jars at 28° C. Subsequently the ammonia was determined by extracting the soil with 10% hydrochloric acid, and distilling an aliquot part of the extract with excess of sodium hydroxide. The nitrates were determined by the aluminium reduction method, 24 hours being allowed for the reduction. The conclusions drawn from the experiments were as follows:—Semi-arid soils frequently fail to nitrify dried blood when added in the proportion of 1%, but nitrification always takes place when the addition of blood is not greater than is usual under field conditions. The addition of 1% of dried blood to such soil frequently caused a large accumulation of ammonia in the soil, although the addition of dried blood or other nitrogenous substances in the form of fertilisers caused no accumulation of ammonia. Hence conclusions drawn from studies of nitrification or the formation of ammonia in semi-arid soils to which 1% of dried blood has been added are of questionable value. Green manures, especially those of leguminous character, undergo very rapid nitrification, and as much as 50% of the nitrogen in the green plant tissues may be converted into nitrates in 30 days. Green manures, therefore, are suitable for the supply of energy for non-symbiotic nitrogen-fixing organisms. An unsatisfactory distribution of soil

nitrate is often caused by the furrow system of irrigation. Thus, in many citrus groves the surface 6 in. of soil contains more than two-thirds of the nitric nitrogen present in the upper 4 ft. This system of irrigation is also responsible for the production of "nitre spots," the surface scrapings of which may contain as much as 1% of nitric nitrogen. The brown colour of these spots is probably due to several factors, and notably to the deliquescent nature of calcium nitrate. Where the furrow system of irrigation is employed it is advisable to apply the fertilisers at a depth below that to which the land is cultivated. The roots will thus be able to assimilate the available food substances, whereas fertilisers applied nearer to the surface are liable to be carried away by the irrigation. Leaching is also responsible for the loss of nitric nitrogen, and this loss may be best prevented by a winter covering crop. The basin or overhead system of irrigation gives a more satisfactory distribution of soil nitrates than the furrow system, and when combined with a mulching system in which the mulch is not too frequently employed, appears to be the most promising system of irrigation. The occurrence of mottled orange-leaves in citrus plants is accompanied by a higher proportion of moisture, and generally also of nitrogen, than is found in healthy leaves. Extreme mottling is often accompanied by a high proportion of nitrates in the leaves, but the relationship is not invariable.—C. A. M.

Nitrates and nitrites: Assimilation of—[by plants]. [*Separation of nitrates from nitrites.*] O. Baudisch. Ber., 1917, 50, 625—660. (See also this J., 1916, 736, 749.)

THE action of iron and of magnesium compounds on plant life may be due to their power of forming complex compounds with certain proteins. A complex compound of iron and dextrose can be obtained by boiling an excess of a solution of dextrose with an iron salt (FeSO_4 , FeCl_3), and adding a large excess of sodium hydroxide to the yellowish liquid. A green precipitate is formed, which on further heating gives a deep, dark brownish-red solution containing iron in a "masked" form. This solution does not react with potassium nitrate, and is very stable towards heat; but it readily reduces nitrites to ammonia or amines. In this way nitrates may be separated from nitrites. Inasmuch as mannose, lactose, and levulose give similar solutions, but mannitol and sucrose do not, it seems probable that the ability to form such compounds is dependent upon the presence of a hydroxyl group closely connected to one of the groups $\cdot\text{CH}:\text{O}$ or CO . The power of reducing nitrites may depend upon the direct coupling of the nitrate molecule to the iron atom, the liberation of oxygen which oxidises the sugar, and the setting free of hydrogen to effect the nitrite reduction. The liberation of oxygen from nitrates, the reduction of nitrites to ammonia, and the oxidation of the latter to nitrite and nitrate are processes of plant metabolism which can be best studied from the chemical standpoint.—E. H. T.

PATENT.

Fertiliser [from sulphite-cellulose waste liquor], and process for making same. E. C. L. Kressel. Camden, N.J. U.S. Pat. 1,225,825, May 15, 1917. Date of appl., July 21, 1914.

SULPHITE waste liquor is mixed with "biological agents," calcium oxide, and sodium chloride or other alkali chloride. The product is a granular, hygroscopic, and non-putrescible mass, and forms a culture-medium for bacterial development and growth in the soil.—J. B. C. K.

XVII.—SUGARS; STARCHES; GUMS.

Sucrose, inulin, and dextrin: Comparative adsorption of— M. A. Rakuzin. J. Russ. Phys.-Chem. Soc., 1916, 48, 1319—1324.

THE author's previous work indicates that the necessary conditions for adsorption include the colloidal state of the adsorbed substance and adsorbent, the only case observed in which a crystalline substance is irreversibly adsorbed by a colloidal adsorbent being that of the solid paraffins of petroleum by aluminium hydroxide, floridin, etc. In order to test the accuracy of Freundlich's rule, that adsorption is prevented by a tendency to dissociation and by an accumulation of hydroxyl groups, the author has now carried out experiments on the adsorption of sucrose, inulin, and dextrin. The results show that this rule holds only for crystalline carbohydrates, such as sucrose, and inulin; colloidal carbohydrates, on the other hand, are well adsorbed by both aluminium hydroxide and animal charcoal, and in the case of dextrin (commercial "*dextrinum purissimum*"), both these adsorptions are irreversible with respect to boiling water. Further, both adsorptions are quantitative; animal charcoal adsorbs 8.04% of β -achrodextrin and aluminium hydroxide 16.02% of products intermediate to β - and γ -achrodextrins. The above commercial dextrin is found to be a mixture of maltodextrin with β -achrodextrin and products intermediate to β - and γ -achrodextrins.—T. H. P.

β -Glucose [β -dextrose]: Preparation of— A. W. Mangum and S. F. Acree. J. Amer. Chem. Soc., 1917, 39, 965—968. (See also Hudson and Dale, this J., 1917, 349.)

THE preparation of β -dextrose by crystallisation from hot aqueous solutions of the sugar does not always yield a pure product, and the following modification of Behrend's method (Annalen, 353, 106; 377, 220) is recommended. α -Dextrose is dissolved completely in boiling pyridine (e.g., 25 grms. in 25 c.c.) and the solution is allowed to crystallise for 24 hours, preferably in an ice-box. β -Dextrose separates with 1 mol. of pyridine, which it loses readily in the air, *in vacuo* over sulphuric acid, or in an oven at 120° C. If the pyridine is completely removed, the product shows an initial specific rotatory power of 20°—25°. The yield is 70—85%.—J. H. L.

Jute plant; Occurrence of raffinose in the seed of the— H. E. Annett. Biochem. J., 1917, 11, 1—6.

JUTE seed, finely ground, was exhausted with ether and with petroleum spirit; the residue was exhausted with alcohol, and a copious white precipitate was obtained on the addition of ether to the alcoholic extract. The crude substance was dissolved in hot 80% alcohol, the solution filtered, and left for several days; a deposit of rosettes of white needles was obtained and was recrystallised from 80% alcohol. The sugar thus prepared did not reduce Fehling's solution and did not yield an osazone; it was identified as raffinose. The quantity of raffinose present in jute seed was determined in an aqueous extract of the seed, after clarification with lead acetate, by determining the fall in rotation produced by the action of invertase and melibiase; in the sample of seed examined the raffinose amounted to about 2.25%.—J. F. B.

Xylose; Preparation of— C. S. Hudson and T. S. Harding. J. Amer. Chem. Soc., 1917, 39, 1038—1040.

COTTONSEED hulls form a convenient material for

the preparation of xylose, and yield 8—12% of the crystalline sugar by a process described, which includes a preliminary steeping in dilute ammonia, boiling with dilute sulphuric acid to hydrolyse the xylan, neutralising with lime, removal of calcium sulphate, acidification with phosphoric acid, decolorisation, concentration, and crystallisation with the aid of alcohol.—J. H. L.

Sedoheptose, a new sugar from Sedum spectabile.
I. F. B. La Forge and C. S. Hudson. J. Biol. Chem., 1917, 30, 61—77.

AN aqueous solution of the leaves and stems of one of the stone-crops, *Sedum spectabile*, was found to contain a non-fermentable heptose, designated sedoheptose. The sugar itself was not isolated, but crystalline phenyl- and bromophenyl-osazones, m.pt. 197° and 227°—228°C. respectively, were prepared and analysed, and a compound of the osone with *o*-phenylenediamine was also obtained. Reduction of the concentrated plant extract with sodium amalgam, yielded two heptitols, α - and β -sedoheptitols, m.pt. 151°—152° and 127°—128°C. respectively. These and their tribenzal derivatives were analysed. The plant extract, which was practically optically inactive, lost about 80% of its cupric-reducing power, and acquired strong levo-rotatory power, on heating with dilute hydrochloric acid, owing to the conversion of about 80% of the sugar into a non-reducing anhydride, $C_7H_{12}O_6$, termed anhydrosedoheptose, m.pt. 155°C., $[\alpha]_D^{20} = -146.3^\circ$, of which a dibenzal derivative was prepared. In aqueous solution this anhydride is reconverted, to the extent of 20%, into the heptose on heating with dilute acid. The heptose is not oxidised by bromine, and as it yields two heptitols on reduction it is regarded as a ketose.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Zymin; The conditions of activation of washed — and the specific function of certain cations in alcoholic fermentation. A. Harden. Biochem. J., 1917, 11, 64—69.

ZYMIN (acetone-yeast) and dried yeast which have been rendered inactive by thorough washing, owing to the removal of the co-enzyme, may be readily restored to an active condition by the addition of potassium pyruvate in presence of a suitable concentration of a phosphate. The carboxylase of the zymase has been shown to be unaffected by washing, and since acetaldehyde is the immediate product of the decomposition of pyruvates by yeast-carboxylase, it was to be expected that acetaldehyde might have a similar influence in restoring activity. The first experiments with acetaldehyde were carried out in presence of sodium phosphate with negative results, but when this salt was replaced by potassium or ammonium phosphate the action of the acetaldehyde was the same as that of the pyruvate. Hence it would appear that potassium and ammonium ions possess a specific function which does not belong to the sodium ion, although the latter is not positively inhibitory; this is in accord with the fact that sodium phosphate cannot replace potassium phosphate in the composition of a synthetic culture medium for yeast. The observation recorded with regard to acetaldehyde would be consistent with the theory that acetaldehyde is an intermediate product in alcoholic fermentation and is reduced to alcohol by hydrogen formed at another stage. It might also be held to favour the suggestion that acetaldehyde may be regarded as constituting the co-enzyme of yeast juice, since

it certainly acts as a co-enzyme with washed zymin provided the phosphates of certain cations are present.—J. F. B.

Bacteria; A new type of chemical change produced by —. Conversion of histidine into urocanic acid by bacteria of the coli-typhosus group. II. Raistrick. Biochem. J., 1917, 11, 71—77.

THE most common chemical change induced in amino-acids by bacterial action is the formation of bases, often toxic, by a process of simple decarboxylation with loss of carbon dioxide. Thus, for instance, histamine and tyramine are formed from histidine and tyrosine by putrefactive bacteria. Another change brought about by bacterial action is "deamination," i.e., the splitting off of ammonia, which however is usually accompanied by hydrogenation, with formation of a saturated acid, under the anaërobic conditions of the experiments. In the present experiments it was considered advisable to carry out the reaction without the presence of other organic substances than the amino-acid under observation. In this way secondary reactions were avoided, although the bacteria did not grow well; this was compensated by copious sowing of vigorous growths (agar slope cultures) and prolonged incubation. For the purposes of the experiment, pure histidine hydrochloride was dissolved in Ringer's solution, with an indicator and sufficient alkali to give a hydrogen-ion concentration, after boiling, of $p_H = 7.35$. The solution was inoculated with 24-hour old cultures of various bacteria of the coli-typhosus group. All these bacteria yielded a substance giving a crystalline picrate, which was identified as the picrate of urocanic (3-iminazolylacrylic) acid. This is an unsaturated acid produced from histidine by the simple splitting off of ammonia without subsequent hydrogenation. Some of the liquids in the culture flasks developed an alkaline reaction, but the production of urocanic acid from histidine is not confined to those bacteria of the group which develop alkalinity; in fact the largest yield was obtained with *B. paratyphosus*. In the cultures of which showed no alkalinity. This type of reaction consisting of deamination to an unsaturated acid has not previously been recorded.—J. F. B.

XIXA.—FOODS.

Foods: Effect of high temperatures on the nutritive value of —. A. G. Hogan. J. Biol. Chem., 1917, 30, 115—123.

THE nutritive value of proteins (albumin, casein, maize proteins, etc.) is not materially lowered when the proteins are heated in an autoclave for 6 hours under 30 lb. pressure.—W. P. S.

Proteins of the peanut, Arachis hypogaea. Distribution of the basic nitrogen in the globulins, arachin and conarachin. C. O. Johns and D. B. Jones. J. Biol. Chem., 1917, 30, 33—38.

THE two globulins, arachin and conarachin (see this J., 1917, 158), yield arginine, histidine, lysine, and cystine when examined by the Van Slyke method. The relatively high percentage of lysine in the proteins of the peanut (earthnut), namely, 4.98% in arachin and 6.04% in conarachin, indicates that this nut might be used to supplement diets deficient in lysine.—W. P. S.

Protein substances: Decomposition of — by the action of bacteria. R. H. Robinson and H. V. Tartar. J. Biol. Chem., 1917, 30, 135—144.

ALL proteins are changed to a greater or less extent by the action of bacteria (*B. subtilis*, *B. mycoides*, and *B. vulgaris*), ammonia being the final product of the decomposition, but in no case is any one form of nitrogen destroyed completely. The rapidity of the action varies with different proteins; casein undergoes no further change after a few days, whilst gliadin continues to yield ammonia for more than 30 days. One and the same organism does not have the same action on

different proteins, and the relative proteolytic activity depends on the protein used. The mono-amino-acid nitrogen and the diamino-acid nitrogen of the protein are the chief sources of the ammonia formed, and the similarity of the changes brought about by acid hydrolysis and bacterial action indicates that the latter is largely hydrolysis to the point of formation of various amino-acids. There is no formation of a toxic substance which would inhibit complete ammonification of a protein.—W. P. S.

Tryptic digestion: Optimum reaction of —. I. J. H. Long and M. Hull. J. Amer. Chem. Soc., 1917, 39, 1051—1059.

THE results of the experiments described indicate that the optimum reaction for tryptic action depends on the nature of the protein substrate. With fibrin the optimum range of hydrogen ion concentration was found to be from 10^{-8} to 5×10^{-9} , and with casein 3×10^{-6} to 5×10^{-7} . The enzyme exhibited considerable hydrolytic activity towards casein at hydrogen ion concentrations sufficiently high to arrest all action on fibrin. In carrying out the experiments, solutions of phosphates (as buffer salts), with hydrochloric acid or sodium hydroxide where necessary, were prepared, with values of p_H ranging from 2.36 to 11.86. Fifty c.c. portions of each were treated with 1 gm. of powdered fibrin or casein. It was found that in general the protein affected the reaction of the solutions, lowering the hydrogen ion concentration in the more acid ones, and raising it in the more alkaline ones. Fibrin appeared to be in equilibrium with a p_H of 6.5 and casein with a p_H of 4.9. After addition of 0.1 gm. of trypsin to each solution, digestion was carried out for 3 hours at 40° C. The concentration of hydrogen ions was again determined, and the amount of hydrolysis which had occurred was estimated by Sørensen's method of formaldehyde titration.—J. H. L.

Proteins, enzymes, toxins and serums: Optical activity of —. M. A. Rakuzin. J. Russ. Phys.-Chem. Soc., 1916, 48, 1251—1291.

THE author has collected from all sources numerical data which have been obtained relative to the optical activity of animal and vegetable proteins and their derivatives, enzymes, toxins, and anti-serums.—T. H. P.

Foods: Process for preservation of — and product thereof. N. C. Fowler, jun., Boston, Mass., U.S.A. Eng. Pat. 106,302, May 12, 1916. (Appl. No. 6811 of 1916.)

EQUAL weights of cereals and fruit are ground together and the mixture is dried. For example, a mixture of maize, wheat-bran, and water is heated at 100° C. for 12 hours, washed prunes are then added, the mixture is pressed and ground, and dried at 225° F. (107° C.). Flavouring substances and about 0.5% of salt may be added, if desired. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 3250 of 1868; 7013 of 1892; 13,600 of 1893; 3108 of 1899; 13,245 of 1905; and 2607 of 1915; this J., 1891, 752; 1906, 774; 1916, 321.)—W. P. S.

Food adapted to promote digestion ; Composite —. N. C. Fowler, jun., Boston, Mass., U.S.A. Eng. Pat. 106,324, May 17, 1916. (Appl. No. 7052 of 1916.)

FINELY-DIVIDED grain, including bran, is ground with fruit, the mixture is dried (see preceding abstract), and a dry culture of bacteria capable of producing lactic acid is added. The proteins of milk, separated from the cream and water, may also be added. The product is mixed with milk or cream for use.—W. P. S.

Curing meats ; Method of producing smoke for —. R. J. Gaudy, Detroit, Mich. U.S. Pat. 1,225,798, May 15, 1917. Date of appl., Nov. 16, 1916.

HEAT is generated by electrical means in a resistance placed on the top of a pile of some smoke-producing material, which becomes carbonised but is not heated sufficiently to ignite. The resistance is allowed to descend by gravity through the pile.—J. H. J.

Dough or flour for bread and bakers' wares ; Method of preparing (A) tubers. (B) legumes for manufacture of —. E. Simons, Cassel, Germany. U.S. Pats. (A) 1,225,877 and (B) 1,225,878, May 15, 1917. Date of appl., Sep. 22, 1915.

(A) TUBERS are subjected to the action of steam below 100° C., and are then dried and crushed. The steam may be replaced by hot gas below 100° C., the effect of which is to produce steam within the tubers and thus disintegrate them. (B) Legumes are submitted to the action of steam as above.—J. H. J.

Protein in any form ; Process of digesting and concentrating — by dissolving it in grape juice. E. Monti, Turin, Italy. U.S. Pat. 1,226,983, May 22, 1917. Date of appl., May 26, 1915.

PROTEIN from eggs, milk, blood, meat, etc., is dissolved in grape juice at 35°–40° C., and the mixture is evaporated at a low temperature until its water content is reduced to 33%.—W. P. S.

Eggs ; Process for desiccating —. T. C. Primavera, Corona, N.Y. U.S. Pat. 1,226,999, May 22, 1917. Date of appl., Mar. 12, 1917.

EGGS are mixed with lemon juice and the mixture is dried at 75°–80° F. (24°–27° C.).—W. P. S.

Malt syrup ; Process of making —. H. T. Neidlinger, Oswego, N.Y. U.S. Pat. 1,227,184, May 22, 1917. Date of appl., Sept. 6, 1912.

MALTED grain is digested with water at 149° F. (65° C.), the temperature is then raised to 171° F. (78° C.), and the liquid portion is separated and evaporated to a syrup of about 36° B. This syrup is cooled rapidly and any precipitate of albuminous matter, etc., is removed.—W. P. S.

Potato peelings ; Preparation of — for the purpose of their industrial utilisation. E. Borrás, Barcelona, Spain. U.S. Pat. 1,226,852, May 22, 1917. Date of appl., June 17, 1916.

SEE Eng. Pat. 100,675 of 1916 ; this J., 1916, 860.

XIXB.—WATER PURIFICATION ; SANITATION.

Water ; Disinfection of — by means of bleaching powder. H. Langer. Z. Hyg., 1916, 84, 296. Chem.-Zeit., 1917, 41, Rep., 166.

A DISTINCTION is drawn between disinfection, i.e.,

rendering bacteria harmless, and the killing of bacteria. In the case of bleaching powder, disinfection is dependent only upon the concentration of the available chlorine, not upon the duration of the exposure. The action is a rapid one, and does not consist in oxidation but in absorption of chlorine. The time required to kill the bacteria depends only upon their power of resistance to the injury effected by the chlorine. Disinfection, therefore, is independent of the time elapsing before neutralisation of the chlorine ; whether this follows at a longer or shorter interval, the killing of the bacteria is not influenced. The presence of organic matter reduces the concentration of the available chlorine, though the amount of this reduction can only be determined by a bacteriological test. The disinfecting action is rendered greater by adding the bleaching powder in fractions, a cumulative effect replacing that of concentration.—J. H. J.

Cholera culture media ; The chemistry of —. G. Seiffert and H. Bamberger. Arch. Hyg., 1916, 85, 265. Chem.-Zeit., 1917, 41, Rep., 165.

THE improved growth of cholera cultures on alkaline blood media is brought about by the hæmoglobin, which can be replaced by other pyrrole derivatives, such as bile pigment and chlorophyll, and by pyrrole itself. This property is possessed also by transformation products of the hæmoglobin, as hæmin and hæmatoporphyrin. In practice, a chlorophyll medium has proved useful, and on this, after addition of fuchsin and sugar, cholera cultures gave a growth of light red colonies. The medium is made shortly before the plates are required, as repeated heating spoils its selective action.—J. H. J.

"Mercurophen," a new antiseptic. J. F. Schamberger, J. A. Kolmer, and G. W. Raizin. J. Amer. Med. Assoc., 1917, 1458. Pharm. J., 1917, 98, 469.

SODIUM oxymercuri-*o*-nitrophenoxide (mercurophen) contains about 53% of mercury, and is an odourless, brick-red powder, freely soluble in water. Against *Staphylococcus aureus*, in the "antiseptic test," it has proved to be fifty times more active than mercuric chloride, destroying the bacteria on prolonged exposure in bouillon in a dilution of 1 : 10,000,000. In a menstruum of ascites fluid, it is 200 times more germicidal against *S. aureus* than mercuric chloride. By the Rideal-Walker method, it exhibits 10,000 times greater germicidal power against *B. typhosus* than phenol, and over thirty times greater activity than mercuric chloride. Mercurophen disinfects the hands in dilutions of 1 : 10,000 to 1 : 40,000 in one minute, whereas mercuric chloride in a dilution of 1 : 5000 requires over five minutes, and in a dilution of 1 : 10,000 requires over fifteen minutes. It sterilises ordinary rubber tubing in thirty minutes in a dilution of 1 : 100,000. Mercuric chloride accomplishes this result in a dilution of 1 : 16,000. The precipitating effect of mercuric chloride on human serum proteins is four to five times greater than that exhibited by mercurophen ; this is an obvious advantage in favour of the latter. It has a lower toxicity than mercuric chloride.

New type of chemical change produced by bacteria. Conversion of histidine into urocanic acid by bacteria of the coli-typhosus group. Raistrick. See XVIII.

PATENTS.

Water ; Apparatus for decarbonating — especially for brewing. E. Werle, Oberglogau. Ger. Pat. 297,178, Feb. 11, 1914.

THE water passes through a series of vessels placed

at different levels, proceeding from the top of one into the bottom of the next higher in the train. In each it is agitated and heated with steam, the gases liberated passing up a stand-pipe rising from the top of each vessel.—H. J. H.

Insecticides, sheep dip, and the like. G. J. Lemmens, Wateringbury, and P. J. Fryer, Tonbridge, Kent. Eng. Pat. 106,133, Dec. 1, 1916. (Appl. No. 17,383 of 1916.)

Finely powdered leaves, seeds, and other portions of the plants known as tephrosia, particularly *Tephrosia vogelii*, constitute the product claimed; soap, sulphur, copper sulphate, etc., may be added according to the purpose for which the product is to be used. (See also Eng. Pat. 17,381 of 1916; this J., 1917, 611.)—W. P. S.

Bacteria and fungi exterminator. W. R. Kleckner, Cowell, Cal. U.S. Pat. 1,227,451, May 22, 1917. Date of appl., Sept. 6, 1916.

THE composition consists of a mixture of equal parts by weight of potassium ferrocyanide, potassium ferricyanide, and potassium thiocyanate; a mixture of hexamethylenetetramine and ammonium cyanide; a mixture of equal quantities of Methylene Blue, Methyl Violet, Malachite Green, and potassium xanthate; and a mixture of flavouring extracts, oxalic acid, and gelatin.—W. P. S.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Atropine: Exact quantitative determination of —. H. Baggesgaard Rasmussen. Ber. Deuts. Pharm. Ges., 1917, 27, 193—201.

In a study of the silicotungstate method of determining atropine (see Javillier, this J., 1910, 1176; 1911, 238), the author found that a moderate excess of the precipitant, e.g., 10%, does not affect the results. The precipitate, after standing for 8 or 12 hours, is collected in a Gooch crucible, washed three times with 1.5% hydrochloric acid, and, in incinerating, is ignited over a Techn burner for 5 mins. after all carbon has been burnt. The residue cannot be ignited to constant weight, owing to the slight volatility of tungstic oxide at high temperatures. The factor for calculating the weight of atropine from that of the ignited residue is 0.4067, and the correction for solubility is 0.0054 grm. of atropine per 100 c.c. of liquid (cf. *loc. cit.*). Where necessary the results may be checked by carrying out a duplicate precipitation and determining the nitrogen in the precipitate, to confirm that the substance precipitated is really atropine or an isomer. A description is given of the application of the method to the analysis of belladonna extracts.—J. H. L.

Digitalis seeds and leaf: The relative proportions of the active constituents in —. W. Straub. Arch. Exp. Pathol. u. Pharmacol., 1916, 80, 52. Chem.-Zeit., 1917, 41, Rep., 158.

THE methods used for the isolation and purification of the active principles of digitalis involve large losses. The estimation has been made physiologically by determining the minimum fatal dose of the total extract and of the single fractions. In the case of the seeds, a cold water extract contained 1.3% of active principles on the dry material, the greater part consisting of substances (*digitalinum rerum* and *digitalein*) not shaken out by chloroform.

The small portion soluble in chloroform apparently contained only traces of these substances. Practically no further quantity of active principles was obtained from the residue by extraction with 96% alcohol. From the leaves, cold water extracted about two-thirds of the active constituents and 50% alcohol about one-third. From the cold water extract chloroform dissolved 61% (*gitalin*), 42% remaining insoluble; the loss of about 12% is probably due to the transformation of the lactone, *digitalein*, into the inactive acid. The treatment of an infusion prepared in the official manner confirmed the observation of Kraft that owing to the high temperature an appreciable loss of water-soluble active glucosides takes place. It is confined to the *digitalein* fraction; the *gitalin* fraction is indeed increased, but apparently through the formation of *digitoxin*, since the real *gitalin* is decreased. Similarly the titration value of the *gitalin* fraction is considerably diminished by heating a cold-water extract and to the same extent that of a chloroform extract of this infusion, as well as of pure *gitalin*. The treatment of the extract with alcohol in the cold also lowers the titration value, confirming the observations of Kraft with *gitalin*.—J. F. B.

Sera: The reaction of — as a factor in the successful concentration of antitoxic sera by the methods at present in use. A. Homer. Biochem. J., 1917, 11, 21—39.

IN the Banzhaf method (Collected Studies Research Dept. Health, New York, 1913, 4, 230) for the concentration of antitoxic sera, uncertainties in the filtration arise from two causes: (A) That no cognisance has been taken of the reaction (hydrogen ion concentration) of the serum. (B) That as the precipitating power of 30% of ammonium sulphate is not appreciably increased during the heating process, a certain amount of euglobulin escapes precipitation with the first fraction precipitate and appears in colloidal suspension in the final product. The uncertainties in the filtration of the hot serum-ammonium sulphate mixtures can be obviated and the complete elimination of the euglobulin can be assured by an adjustment of the hydrogen ion concentration to the point at which the desired increased precipitation is assured, also by brine extraction of the second fraction precipitate containing the pseudo-globulin-antitoxin combination together with the small amount of euglobulin which has escaped precipitation with the first reaction, and, thirdly, by subjecting the serum to a preliminary prolonged heating at 57°—58° C. whereby the precipitation of the serum proteins is considerably enhanced. Assistance is also derived from the addition of organic substances such as phenol and its homologues, ether, or chloroform, which increase the precipitation of the serum proteins, presumably by virtue of their effect on the surface tension of the protein aggregates in colloidal solution, but these additions must be made with caution. The extent of the heat denaturation of the serum proteins during the heating of serum at 57° C. for several hours is also influenced by the hydrogen ion concentration of the serum and can be controlled by the adjustment of the latter. The denaturation induced by heat in alkaline sera apparently does not involve the same type of change as that induced in acid sera.—J. F. B.

Tuberculin: Selective adsorption of Denys' — by aluminium hydroxide. M. A. Rakuzin and G. D. Flier. J. Russ. Phys.-Chem. Soc., 1916, 48, 1316—1319.

TWO samples of tuberculin, prepared by (1) Vermet, Moscow, and (2) L'Institut de Bactériologie de Louvain, have been examined. Both preparations were straw-yellow and neutral, and

the other physical properties were: (1) sp. gr. 1.0223 at 15° C., c (dry matter, per cent.) 6.3134, $[\alpha]_D = -9.81^\circ$ and (2) sp. gr. 1.01944 at 15° C., $c = 2.285$, $[\alpha]_D = -21.22^\circ$. Both contained free ammonia and showed Adamkiewicz's, Molisch's, Pettenkofer's, Ostromyslenski's, Liebermann's, and the xanthoprotein reactions (compare this J., 1916, 433), but the limits of sensitiveness differed widely in the two cases; only the Louvain preparation gave Millon's reaction and neither gave the biuret reaction. Aluminium hydroxide adsorbed 7.62% and 23.08% of the respective preparations and both adsorptions were irreversible as regards boiling water. With reference to the colour reactions of the proteins and to the rotatory power, the products of adsorption behaved similarly to the original tuberculin.—T. H. P.

Antidiphtheritic serum: Selective adsorption of — by aluminium hydroxide. M. A. Rakuzin and G. D. Flier. J. Russ. Phys.-Chem. Soc., 1916, 48, 1324—1330.

It has been shown previously that the adsorption of enzymes and toxins, especially by aluminium hydroxide, is in most cases selective, and the investigations have now been extended to antidiphtheritic serum. The serum employed, sp. gr. 1.0340 at 15° C., $[\alpha]_D = -28.876^\circ$, was straw-yellow and of neutral reaction. It gave the following protein colour reactions with the degrees of sensitiveness indicated in brackets (compare this J., 1916, 433): biuret (1:660), Millon's (1:330), Liebermann's (1:2500), Adamkiewicz's (1:9000), xanthoprotein (1:660), Molisch's (1:330), Pettenkofer's (1:1250) and Ostromyslenski's (1:1250). The adsorption by aluminium hydroxide proceeds irreversibly and with quantitative separation of the toxin, the proportion of the latter adsorbed being 43.47%. The liquid remaining after the adsorption is colourless and neutral and gives all the above colour reactions of the proteins.—T. H. P.

Desoxycholic acid; Preparation of —. W. Mair. Biochem. J., 1917, 11, 11—13.

In investigating the solvent action of bile salts on pneumococci it was found that sodium desoxycholate was ten times more active than sodium cholate or commercial sodium taurocholate. A method for the separation of desoxycholic acid from the crude mixture of bile acids has been worked out. To 4 litres of ox bile is added 240 grms. of caustic soda; when the soda is dissolved, the liquid is boiled gently in an iron digester for 20 hours; the volume should then be between 2 and 3 litres. While still hot the liquid is made neutral to phenolphthalein by adding gradually about 350 c.c. of strong hydrochloric acid. A flocculent precipitate of silica is formed but none of the bile acid is thrown out if the liquid is sufficiently warm. After cooling, the bile is filtered; the filtrate is made acid to litmus by adding about 50 c.c. of glacial acetic acid. The bile acids separate out as a fluid crystalline mass, white at first but rapidly absorbing pigment; the acids are caused to adhere in a single mass by rotating the flask, and the mother liquor is decanted. The mass is squeezed, transferred to a flask, and dissolved in rather more than an equal volume (about 600 c.c.) of glacial acetic acid by warming on the water-bath. The solution is allowed to crystallise by standing for 2—3 days, the mixed crystals containing practically all the desoxycholic acid, a nearly equal amount of cholic acid, and some fatty acid. The crystals are filtered off, washed free from pigment with 60% acetic acid, drained as dry as possible, and redissolved by heating with 300 c.c. of glacial acetic acid. The next crop of crystals is pressed between porous tiles and redissolved

by boiling with 750 c.c. of 60% acetic acid; the solution is filtered, any fatty matter is skimmed off after cooling, and the crystals which separate are washed first with 60% acetic acid, then with water, and are finally pressed and dried at 100° C. The product is practically pure desoxycholic acid, m.pt. 172°—173° C.; the yield from 4 litres of bile is 32—42 grms.; the yield from 1000 grms. of commercial taurocholate is 50 grms. The method is only recommended where a maximum yield of desoxycholic acid is required and the cholic acid may be neglected; the latter may, however, be recovered after distilling off the acetic acid from the mother liquors. In general it is better to follow Schryver's method (J. Physiol., 1912, 44, 265) for the preparation of cholic acid.—J. F. B.

PATENTS.

Compound for internal administration; Metallic —. W. B. McLaughlin, New York, U. S. Pat. 1,226,229, May 15, 1917. Date of appl., Aug. 5, 1916.

THE compound consists of an iron or a calcium soap dissolved in stearic acid.—J. H. J.

Iodine compound and method of preparing same. H. P. Slater, Cedar Rapids, Iowa, U.S. Pat. 1,226,394, May 15, 1917. Date of appl., Nov. 15, 1915.

SOLUTIONS of hexamethylenetetramine and iodine are mixed at room temperature, when a precipitate of hexamethylenetetramine periodide is produced; this is filtered off, washed, and treated with ammonia, when a finely-divided, red powder is produced, which is dried at room temperature. Instead of filtering off the addition product, it may be treated, while suspended in its mother liquor, with ammonia.—J. H. J.

XXII.—EXPLOSIVES; MATCHES.

PATENTS.

Moulding of gunpowder and similar mixtures; Process for —. J. Lersch, Niederdielfen. Ger. Pat. 296,245, Nov. 3, 1912.

SULPHITE-CELLULOSE waste liquor, concentrated to 35° B. (sp. gr. 1.32), is proposed as binder for components of moulded explosive mixtures, such as nitrates, carbon, sulphur, wood meal, aluminium powder, etc. The moulded product is hard, convenient to handle, impenetrable to moisture, and the products of combustion are less disagreeable than when other materials are used.—H. J. H.

Match boxes and the like; [Cellulose ester] composition for waterproofing the striking or abrasive surfaces of — A. V. St. Armande, Nitschill, Renfrewshire, Eng. Pat. 106,375, Aug. 16, 1916. (Appl. No. 11,593 of 1916.)

The striking surface for ordinary and safety matches is rendered waterproof by the application of a varnish consisting of a solution of cellulose nitrate, acetate, formate, propionate, or the like, or a derivative of cellulose such as celluloid. Other substances such as resins, camphor, acetanilide, oils, pigments, dyes, etc., may be added. —W. F. F.

Blasting cartridge. W. Weber, Hayingen, Germany. U.S. Pat. 1,226,833, May 22, 1917. Date of appl., Oct. 1, 1915.

SEE Eng. Pat. 12,163 of 1915; this J., 1917, 101.

XXIII.—ANALYSIS.

Filter paper; Reducing matter extractable from — R. S. McBride and J. A. Scherrer, J. Amer. Chem. Soc., 1917, 39, 928—933.

THE authors conclude that there is undoubtedly some substance in most filter papers which is readily extracted and which reduces permanganate. The quantity is sufficient to cause error if a permanganate titration is to be made after filtration, particularly if the permanganate is dilute (N/50 or N/100) and the titration is made in hot solution. Apparently most of the reducing material is removed in the first washings and therefore a preparatory washing with about 25 c.c. of reagent is sufficient to avoid subsequent error, even if titration takes place in the presence of the paper, or even if the paper is very old. —W. H. P.

Dialysis; Technique of preparing membranes for — W. Brown, Biochem. J., 1917, 11, 40—57.

THE principle adopted in a previous investigation (this J., 1915, 1118) for preparing collodion membranes of graded permeability is capable of general application to a large variety of membranes and liquids. Given a membrane substance, a restraining liquid, *A*, of which the membrane substance imbibes only a negligible amount, and a swelling liquid, *B*, strongly imbibed by the membrane substance, then if *A* and *B* are miscible in all proportions, membranes of graded permeability may be obtained by steeping films of the membrane substance in mixtures of *A* and *B*, and subsequently washing in *A*; the higher the percentage of *B* in the mixture the greater is the permeability of the membrane. The great majority of membranes prepared in this way are of a type suitable for use in the restraining liquid. Of this type the author has prepared graded membranes of collodion in water, benzene, chloroform, etc.; of agar and gelatin in alcohol, acetone, benzene, etc.; of cellulose acetate in water, alcohol, benzene, etc. It is obvious that when the membrane is required for use in a liquid which is not imbibed by it but which, owing to its immiscibility with the swelling liquid *B*, cannot be used directly as the restraining liquid, the latter can be displaced by the third liquid after the membrane has been graded. For instance, membranes of gelatin or agar, graded by alcohol and water, may be prepared for use with benzene by subsequent displacement of the alcohol by

means of the latter. The type of membrane graded for use in the swelling liquid, *B*, can only be prepared when a method exists for suppressing the capacity of the membrane substance to imbibe *B*, this suppression to be brought about at the stage where the membrane is still immersed in the mixture of *A* and *B*. Up to the present only one representative of this type has been prepared, *viz.*, gelatin membranes graded with alcohol and water, prepared for use in water by the prolonged action of formaldehyde. The degree of permeability of graded membranes may be expressed by the ratio of dry weight to wet weight of the film. —J. F. B.

Barium sulphate; Properties of — Z. Karaglanow, Z. anal. Chem., 1917, 56, 225—246.

BARIUM sulphate was prepared free from occluded chloride by dissolving in concentrated sulphuric acid and re-precipitating by dilution with water. By heating to varying temperatures in a platinum or porcelain crucible, no appreciable change was observed at the temperature given by a Teclu burner, but with a blow-pipe flame a loss of weight occurred through decomposition into sulphide, which was greater with the platinum than with the porcelain crucible. On igniting the precipitate in contact with filter paper over a gas flame, no change of weight occurred when a platinum crucible was used, but with a porcelain crucible, a diminution from 0.1622 to 0.0618 gm., through reduction to sulphide was observed. The solubility of barium sulphate in water and in different electrolytes was measured by agitating the precipitate for 24 hours in contact with the liquid and determining the loss in weight. In pure water the solubility was found to be 0.0013 gm. per litre, or 1 part of barium sulphate in 232,588 parts of water. The greater solubility over that previously estimated is in part due to the fine state of division of the precipitate used in the present measurements. In the presence of barium chloride or sulphuric acid, the solubility of the sulphate was found to be lowered in accordance with the law of constant solubility product of anion and cation. With potassium chloride and nitrate an increased solubility was obtained which was greater in the latter case and which is attributable to double decomposition giving potassium sulphate and barium chloride or nitrate, an action which is favoured by the low degree of dissociation of the two last compounds. The solubility increased in presence of potassium chloride in proportion to its concentration. With calcium chloride, at a concentration of 0.36N and below, no influence was exerted on the solubility, but at higher concentrations the solubility was diminished, which is due to the calcium sulphate giving, through primary dissociation, more sulphate ions than potassium sulphate. With strontium chloride the solubility of the barium sulphate was increased to a greater degree than with potassium chloride, owing to the lower solubility of strontium sulphate as compared with calcium sulphate and consequent formation of fewer sulphate ions. With lead nitrate at a concentration of 0.118N, the solubility was diminished, but at lower concentrations was increased, a maximum value being obtained with 0.03N, below which the solubility again diminished. In ferrous sulphate solution containing free sulphuric acid, no loss of weight was obtained, but in some cases a slight increase through adsorption. With ferric chloride the solubility was found to be considerable, and to vary with the concentration of the chloride; it was increased by the presence of hydrochloric acid, and arrested if barium chloride was also present. With hydrochloric acid alone, the solubility was greater than with the alkali chlorides and depended on the concentration of dissociated hydrogen chloride, indicating the reaction,

With nitric acid solution, the solubility was still higher, varying with the concentration and amounting to 0.142 gm. in 200 c.c. of a 2.8*N* solution, though the sulphate is practically insoluble in nitric acid if the solution also contains either barium chloride or sulphuric acid.—J. N. P.

Potassium and sodium in the form of sulphates: Determination of — by platinum chloride. B. Turkus. Ann. Chim. Analyt., 1917, 22, 101—102.

The determination of potassium by platinum chloride is generally carried out after conversion of the sulphates into chlorides, but in certain cases, particularly in the case of silicates decomposed by hydrofluoric and sulphuric acids, the removal of sulphates is tedious and it is far more convenient to treat the solution of mixed alkali sulphates direct. The theoretical quantity of platinum chloride, plus 50% excess, calculated on the supposition that the whole of the sulphate is sodium sulphate, is added to the solution in small portions, then a few drops of strong hydrochloric acid, and before each addition the solution is evaporated to dryness to eliminate as far as possible the free acids. The residue is treated with 85% alcohol with the addition of one drop of ether; the sodium platinichloride is dissolved and the potassium compound remains insoluble. The residue is washed several times before being brought on the filter and the washing is continued until the filtrate becomes colourless. The potassium platinichloride is collected on the filter while it is still moist; the filter is incinerated at first with gentle heat and afterwards at dull redness until white fumes of potassium chloride cease to be evolved. The contents of the crucible are washed with hot water and the platinum digested on a water-bath with a little dilute hydrochloric acid, washed, and incinerated, finally over the blowpipe, until the weight is constant. The results are satisfactorily accurate and the method is recommended for the determination of alkalis in silicates.—J. F. B.

Tin and antimony: Separation of — by hydrogen sulphide in hydrochloric acid solution. A. Prim. Chem.-Zeit., 1917, 41, 414—415.

THE separation is effected by precipitation of the antimony from the mixed solution by hydrogen sulphide in a hydrochloric acid solution of definite concentration, which must be rigidly adhered to. The mixed solution is placed in an Erlenmeyer flask (300—350 c.c.), 60 c.c. of hydrochloric acid (sp. gr. 1.19) is added and the volume made up to 200 c.c. The solution, raised to boiling point, is treated with a rapid current of hydrogen sulphide for 10 mins., after which a slow current is employed while the solution cools down to air temperature. The antimony sulphide is filtered off and washed with a hydrogen sulphide solution containing 60 c.c. of hydrochloric acid (sp. gr. 1.19) in 200 c.c., a final wash with water being given. The filtrate is collected in a 250 c.c. graduated flask, made up to the mark and shaken up at once. The antimony sulphide is returned to the precipitation flask and brought into solution by boiling with 20—25 c.c. of hydrochloric acid (sp. gr. 1.19) and an equal volume of water, a funnel being placed in the neck of the flask. 30—40 c.c. of water is added and boiling is continued for 10 mins. After cooling, 2 drops of phenolphthalein solution, 2—3 grms. of Rochelle salt, and then a slight excess of sodium hydroxide are added. The solution is slightly acidified with hydrochloric acid, and 20—25 c.c. of saturated sodium bicarbonate solution is added. The solution is titrated with an iodine solution standardised against pure tartar emetic. The tin is determined in 100 c.c. of the filtrate from the antimony sulphide.

50 c.c. of water and 2—3 grms of iron powder or wire are added. The flask used is closed by a stopper carrying a tube dipping into caustic soda. By boiling, the hydrogen sulphide is driven off and the tin is reduced. The vessel of soda is replaced by one of sodium bicarbonate and the tin solution allowed to cool, so that air is excluded. 100 c.c. of air-free water and starch solution are added and the solution is titrated with iodine solution standardised against a similarly prepared solution of tin.—H. Detection of peanut [arachis] oil in olive oil. Lund. See XII.

Determination of unsaponifiable matter in oils, fats, and waxes. Wilkie. See XII.

Rapid method of determining the suitability of oils for soap-making. Lecocq. See XII.

Influence of the presence of calcium carbonate on the determination of available phosphoric acid in soils by Dyer's method. Sen. See XVI.

Assimilation of nitrates and nitrites [by plants]. [Separation of nitrates from nitrites.] Baudisch. See XVI.

Chemistry of cholera culture media. Seiffert and Bamberger. See XIXb.

Exact quantitative determination of atropine. Baggesgaard Rasmussen. See XX.

PATENTS.

Combustible gases; Apparatus for detecting the presence of— A. Philip and L. J. Steele. Portsmouth, Eng. Pat. 106,127, Nov. 22, 1916. (Appl. No. 16,750 of 1916.)

Is apparatus of the type described in Eng. Pats. 27,281 of 1911 and 5167 of 1913 (this J., 1913, 455; 1914, 378) in which two wires of catalytically active material are exposed to the atmosphere to be tested and two similar wires are protected from exposure to the atmosphere, the two pairs of wires being connected in opposite arms of a Wheatstone bridge, the inactive wires are enclosed in a chamber at the same pressure as the surrounding atmosphere. The chamber may be closed except for a connection to the surrounding atmosphere by a tube of great length and fine bore, so that it is sensitive to pressure changes but not to changes in the composition of the atmosphere. Alternatively, the chamber may be entirely closed, one surface containing an adjustable flexible diaphragm.—W. F. F.

Temperature-measuring instrument. T. Spooner, Wilksburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,227,337, May 22, 1917. Date of appl., May 28, 1913.

Two thermocouples are used, a main thermocouple the hot junction of which is at the temperature to be measured, and an auxiliary thermocouple the cold junction of which is at the temperature of the room. The cold junction of the main thermocouple and the hot junction of the auxiliary thermocouple are kept at the same temperature in a single receptacle. A potentiometer and the necessary auxiliary apparatus and connections are provided, whereby the temperature difference between the hot and cold junctions of the main thermocouple is measured, and the indication increased by an amount proportional to the temperature difference between the hot and cold junctions of the auxiliary thermocouple.—W. F. F.

Books Received.

Forty-first Annual Report of His Majesty's Inspectors of Explosives. 1916. [Cd. 8609.] Price 1d. (See page 694.)

EXPLOSIVES. By ARTHUR MARSHALL. Second Edition. Vol. I. History and Manufacture. Vol. II. Properties and Tests. 795 pages. J. and A. Churchill, 7, Great Marlborough Street, London. Price £3 3s. for the two volumes.

Less than two years has elapsed since the publication of the first edition of this work (see this J., 1915, 583); its value may therefore be taken as established. The book has been much enlarged and new illustrations provided. The manufacture of picric acid, trinitrotoluene, and other nitro compounds receives much fuller treatment in this edition, and French explosives and methods are also described in greater detail, advantage being

taken of the publication of "*Les Poudres et Explosifs*," by L. Vennin and G. Chesneau. It may be mentioned that the present edition is dedicated to the Prime Minister, whose portrait is given as frontispiece to Vol. I. Photographs of Berthelot, Sobrero, Nobel, Abel and Mendeléeff from the frontispiece of Vol. II.

TRATTATO DI CHIMICA ANALITICA APPLICATA. Metodi e norme per l'esame chimico dei principali prodotti industriali ed alimentari. Vol. II. Di V. VILLAVECCHIA, Direttore dei Laboratori Chimici delle Gabelle, con la collaborazione dei G. FABRIS, A. BIANCHI, G. ARMANI, G. ROSSI, G. SILVESTRI, G. BOSCO, R. BELASIO, F. BARBONI, ed A. CAPPELLI. U. Hoepli, Milan. XV. + 719 pages, 9½ by 6½ ins., with 105 illustrations. Price L. 18.50.

This is the second volume of Prof. Villavecchia's treatise on applied analytical chemistry, the first volume of which has been previously noticed (see this J., 1916, 1181). The present volume contains sections on: meat and its preparations (29 pages); milk and dairy products (36 pages); flour and starch, and products derived from them (51 pages); sugars and products containing sugar (109 pages); beer (16 pages); wine (74 pages); spirits and liqueurs (70 pages); essential oils (34 pages); turpentine and its products (20 pages); varnishes (10 pages); rubber and gutta-percha (12 pages); tanning materials (22 pages); inks (10 pages); leather (14 pages); colouring matters (91 pages); textile fibres, yarns, and fabrics (107 pages). There is also an alphabetical index covering both volumes.

COMBINAZIONI CHIMICHE FRA METALLI. Di M. GIUA e C. GIUA-SOLLINI. U. Hoepli, Milan. XVI. + 446 pages, 9½ by 6½ ins., with 207 illustrations. Price L. 12.50.

THE present work is that which gained the prize offered in 1915 by the *Reale Istituto Lombardo di Scienze e Lettere* for the best monograph on "Intermetallic compounds." The book comprises chapters on equilibrium diagrams; thermal analysis; nature of intermetallic compounds, including some hitherto unpublished results of experimental work on the degree of dissociation of such compounds; influence of intermetallic compounds on the physical properties of alloys; homopolar intermetallic compounds, i.e., compounds of true metals; heteropolar intermetallic compounds, i.e., compounds of metals with metalloids; ternary intermetallic compounds. The work is completed by a bibliography, an index of authors' names, and an index of the known intermetallic compounds.

TRADING WITH THE ENEMY. Consolidating statutory list of persons and firms in countries, other than enemy countries, with whom persons and firms in the United Kingdom are prohibited from trading. (With notes to British merchants engaged in foreign trade.) Complete to June 22, 1917. No. 29a. H.M. Stationery Office, London. Price 6d. net.

TRADE PRODUCTS OF THE BRITISH EMPIRE. Special Supplement to Chamber of Commerce Journal. July, 1917. Oxford Court and 97, Cannon Street, London. E.C.4. Price 1s.

A STATISTICAL account of the resources of the British Empire in regard to supplies of foodstuffs and of raw materials for British industries.

The Society of Chemical Industry.

Official Notices.

At the Annual General Meeting of the Society of Chemical Industry held at Birmingham on 18th July, 1917, the following Resolution was submitted by the President, Dr. Charles C. Carpenter, seconded by Mr. J. H. Hoseason, and unanimously agreed to:—

"The Council of the Society of Chemical Industry, having considered the matter, recommend, and it is hereby resolved, that—

"(1) The yearly subscription for Members of the Society shall, from 1st January, 1918, be 30s. in place of 25s. as at present;

"(2) The amounts payable for Life Composition under By-law 11 shall each be increased by £5; and

"(3) It is therefore also resolved that By-laws 10 and 11 be altered accordingly."

In terms of Paragraph 38 of the Society's Charter, a General Meeting of the Society is hereby called to be held at Broadway Chambers, Westminster, London, S.W., on Wednesday, 15th August, at 4 p.m., for the purpose of confirming the above Resolution.

J. P. LONGSTAFF,

General Secretary.

30 July, 1917.

LIBRARY CATALOGUE OF CHEMICAL JOURNALS.

Owing to the great activity in chemical industries which has arisen during the last few years, the Council felt that a Catalogue of current Journals dealing with chemistry and chemical industries and the Libraries in which they could be found would be of considerable value, and a Committee was appointed last year to take this matter in hand. The work is not yet completed, but as a great deal has been done it may interest members to know the scope and present state of the Catalogue.

The list of Chemical Journals, about 5000 in number, comprises all those abstracted by the Society of Chemical Industry, Chemical Society, American Chemical Society, Science Abstracts (Chemistry), and contained in the Patent Office Library, Royal Society Library, International Catalogue of Scientific Journals (Chemistry), Smithsonian Collection of Chemical Periodicals, and the *Chemisches Centralblatt*. In addition some thousands of Journals dealing with textile, engineering, and other industries have been added, as these often contain articles of value to chemists, or are industries in which chemistry plays an important part. This list is now practically complete.

About 800 Libraries have been communicated with, and asked to send lists of the Journals taken by them or to mark on copies of our list those contained in their Libraries. This part of the work is steadily progressing, and the Journals from our list which are to be found in over 200 Libraries have been already catalogued.

Patent specifications are also listed.

Though the whole Catalogue is not yet complete, members of the Society wishing to avail themselves of the list and library data already collected, in order to find out the whereabouts of any particular Journal which may not be taken in the Library of their own town, will be given all available information on applying to Dr. A. Holt, Chemical Dept., The University, Liverpool.

FUEL RESEARCH BOARD.

The Fuel Research Board, with the sanction of the Committee of the Privy Council for Scientific and Industrial Research, has appointed a Committee of enquiry into the utilisation of Irish peat deposits.

The terms of reference to the Committee are as follows:—"To enquire into and to consider the experience already gained in Ireland in respect of the winning, preparation, and use of peat for fuel and for other purposes, and to suggest what means shall be taken to ascertain the conditions under which, in the most favourably situated localities, it can be profitably won, prepared, and used, having regard to the economic conditions of Ireland; and to report to the Fuel Research Board."

Though the enquiries of the Committee will ultimately lead up to the consideration of peat as a source of energy in central power stations, there are sound reasons why this aspect of the problem should be postponed to a later stage. On the one hand, the Fuel Research Board is already organising an extensive enquiry into the problems of fuel economy in connection with power production, and the results of this enquiry will supply the fundamental data and information which will be required when the time comes for the consideration of any wide scheme of development in Ireland. On the other hand, any schemes of development must be based on a more exact knowledge than is at present available regarding the selection of the more favourably situated bogs and the possibilities of winning and transporting partially dried peat to centres at which it may be converted into marketable products. It is obvious, therefore, that the enquiries of the Committee are likely to be most fruitful if they are concentrated on the fundamental problems, for until these are settled no satisfactory progress can be made.

The following appointments have been made to the Committee:—Sir John Purser Griffith (Chairman), Professor Hugh Ryan, Professor Sydney Young, F.R.S., Mr. George Fletcher, and Professor Pierce Purcell (Secretary). All communications should be addressed to: The Secretary, The Peat Enquiry Committee, University College, Dublin.

Note: The Offices of the Department of Scientific and Industrial Research (including the Fuel Research Board) have been removed to 15, Great George Street, Westminster, S.W.1.

PROCEEDINGS

OF THE

THIRTY-SIXTH ANNUAL GENERAL MEETING, BIRMINGHAM,

WEDNESDAY, JULY 18TH, 1917.

The Thirty-sixth Annual General Meeting of the Society was held on July 18, 1917, at the University of Birmingham. Dr. Charles Carpenter, the President, in the chair. About 200 members were present.

The Lord Mayor of Birmingham (Ald. A. D. BROOKS) extended a hearty welcome to the members of the Society on the occasion of their visit to Birmingham, and recalled the occasion of their previous visit in 1907. It was the duty of all men, whatever their attainments, to place their services at the disposal of the

State during the present crisis. One of their great objects was to see how far they could assist, in the first place in the prosecution of the war; and, secondly, how they might best be able to help the country after the war. The present struggle differed from the wars of the past in that it was carried on primarily by scientific methods; those who had followed the progress of hostilities had been impressed by the extraordinary development that had taken place with regard to the application of science to warfare. They, as chemists, were now concerned in producing means by which human life could be destroyed; and many gases that it had been desired to eliminate as dangerous to human life were now being produced for the purpose of destroying human life. The experience thus gained would be of enormous advantage after the war if proper use were made of the lessons which were now being learned. Before the war this country had shown a lack of initiative and enterprise. We had allowed many important industries to slip away from us and to pass into the hands of other countries which were now our enemies, to their advantage and our disadvantage. Such things must not be allowed to happen again. In order to succeed in the future it would be necessary to conserve and apply all the resources at our command and to conduct our national and commercial affairs on a sound and economical basis; and the surest way to do that was to make use of all the scientific and technical methods at our disposal. It was for that reason he had so much pleasure in welcoming the Society to Birmingham. Many of its industries depended largely for their success on the recovery of what, in the past, had been termed waste products. A great deal had been done in the direction of their recovery; still more remained to be done. There were certain kinds of coal which it was not profitable to use in the ordinary sense but which might be profitably utilised by the application of chemical methods. There was a large amount of heat being lost up the chimneys, which might be recovered and made use of for other purposes. The war had revealed our deficiencies; it had also revealed our powers of adaptability. It was for us to profit by experience. He hoped that their visit to Birmingham might be enjoyable, interesting, and profitable.

PRESIDENT'S ADDRESS.

The CHAIRMAN then delivered his Presidential address, as follows:—

It was my privilege a year ago to address you amid surroundings which have long been a fruitful source of inspiration in belles-lettres. We meet to-day in a city renowned as being essentially material and practical in its character. If the connection with it of one of the greatest chemists of the eighteenth century is not so close as that of the greatest of mechanical engineers, we may remember that it was here he suffered martyrdom for his opinions. It would not, indeed, require a great stretch of the imagination to look upon this gathering as a pilgrimage to the shrine which will ever be associated with the memory of two famous men, the discoverer of oxygen and the inventor of the modern steam engine. And in this double circumstance may be found a theme whose many phases might in themselves constitute full justification for this assembly. If we seek the basis upon which the structure of modern industry has been erected, I think we shall find it largely in the sciences of mechanics and of chemistry; they may indeed be regarded as the first parents of technical industry as it exists to-day. The mechanical engineer will not be likely to dispute the influence of Watt

nor will the analytical chemist be likely to deny indebtedness to Priestley. It is true our present-day vision of the future is not quite the same as that which illuminated the minds of these two great men. But the steam engine the one designed is just as essential an adjunct of the modern power plant as is the chemistry practised by the other to the modern synthesiser of new substances. With the future of our Empire is closely bound up progress in applied science, and, of a certainty, chemical science, and this progress is impossible of achievement without the complete and sympathetic collaboration of both chemist and engineer. It is my belief that with one or two notable exceptions this was not recognised to the full by many manufacturers in this country, certainly until recently. Let me give as an example of what I mean a supposititious case. Suppose the average chemical practitioner were faced with the task of translating a process from the laboratory to the works scale, involving, say, an organic fusion. His conception of carrying this out has not in many instances extended beyond a metal fusion pot with perhaps a run-off cock, having an external furnace and an internal stirrer. This would be as near as he would be likely to visualise on the large scale a familiar process of the laboratory, and, of course, failure to obtain yields would ensue. Such a piece of apparatus might have been useful to a road authority for heating tar by the roadside, but it would be clearly useless for the purpose under consideration. The progress of the chemical industry requires the inspiration of the chemist in all and every direction; that, of course, goes without saying, but what I do urge is that the greatest possible advantage be taken of the engineer's particular gifts to bring about its achievement, once he is made to understand the conditions to be aimed at. The task may not be an easy one, for the temperaments of the chemist and the engineer are dissimilar, and the best examples of both are rarely met with in the same individual. The sorting-out process should begin at school. It should not be left to chance for the lad whose natural bent is along either of the paths which I am now discussing to make his choice of one. If the teaching authority has properly guided and taken pains it should be an easy task to sift the pupil's leanings and direct his course in accordance with them.

But as a preliminary step towards this, the first principles of experimental science should be compulsorily taught in all primary schools, as for instance, is drawing. The ignorance of even the language of science among not only what are called the working classes, but the governing ones also, is appalling, and the only remedy is its universal teaching. I remember hearing on the occasion of a State official being introduced to a highly technical department of which he was to assume control the apologetic utterance, "Gentlemen, in the matters with which you are concerned I am more of a layman than the ordinary layman." While one could not but admire the British pluck underlying such a confession, one could not but be shocked at the system which gave the opportunity for it.

Fortunately, the task of those who are endeavouring to push forward science into the forefront of our educational system is made simpler to-day by the fact that we have no longer to argue the necessity. I might almost say the paramount necessity, of the chemical industries to the nation. But how are we to take full advantage of the latent capacity of our youth unless we teach one and all that the pursuit of chemical knowledge is a calling as honourable and praiseworthy as that of any other of the professions? We have all, I expect, come across men with a strong, natural interest and ability for chemical pursuits which they followed by the merest chance and not as a

matter of course. Their rising to important positions in the chemical industry should have been by design rather than accident. Now here is one of the cases where the community requires and is entitled to have the help of the State. Our educational system needs alteration at its foundations. In my opinion a boy is old enough to learn science when he is old enough to learn history and geography. When he reaches the age of sixteen he should commence work either at the desk or in the factory with compulsory attendance at Continuation Schools. After two or three years he will, if showing himself to possess the necessary ability, be fit for entrance to the University to follow a further course of study along paths adapted to his temperament and qualities. In the past the nation's youth has been developed as unscientifically as its fuel resources. We have seen enough during these last three years to realise that our future depends upon the highest development of our industries, in which the whole populace must be trained to take its share as a pleasure no less than as a necessity. The taunt that we were a nation of shop-keepers was fast becoming a fact when our rude awakening came a century later; if we ever deserve another such rousing our sleep will prove eternal. There were doubtless many contributory causes, but the plight of chemical industry in this country was principally due to the fact that so small a part of the nation was taught its language. The nation cannot be expected to appreciate science at its true value unless that appreciation is inculcated as thoroughly as patriotism, for instance. The next point to be remembered is that the industrial chemistry of to-day is not largely a matter of pots and pans, but a highly complex combination in which temperatures and pressures of fine gradations and extended limits play important parts. The more one sees of this position the more imperative does it appear that the chemist and the engineer should get into double harness as quickly as possible; the very faults of each make him indispensable to the other. In man's war upon nature to wrest her secrets and use them to his advantage, chemist and engineer may be looked upon as playing parts like those of Army and Navy respectively, the one planning his moves upon the contour of an immobile land, the other upon ever-changing waters. Chemical industry teems with examples where the collaboration of both has been successful in extending its fields of usefulness. Take, for example, what is perhaps almost the oldest, that of glass-making; it is the engineer who has made possible the large scale manufacture of jars and bottles to an extent that was quite out of the question as long as the metal required human lungs and hands to blow and fashion it.

The importance of the chemical industries in the scheme of national defence and national progress is at last becoming understood, and must be taken into account in the re-fashioning of our educational system. Another essential change is in our knowledge of the raw material resources of the Empire. Possession of the better maps contributed to the successes of the victors of 1870. And it must be a State matter to map out all our mineral resources that they may be placed at the disposal of industry by, and, I have come to the conclusion, under the control of, the State. I cannot picture a future in which it is possible to work our mines, for instance, with regard only to the present, or in which anything but a surplus output goes abroad before home requirements are satisfied. It should be an offence to supply coking coals for ships' bunkers even though the price paid is a good one. The State must consider whether it is better to export coal for steel-making by our competitors, or to send them the finished article. And if we send our raw materials abroad their sale should be made a matter of inter-State exchange and barter. It ought to be possible to make a

beginning by exporting coke instead of coal and thus increase our control of by-products, the need for which is rapidly increasing. We should thus work up the nitrogen content of our own coal and export this instead of the mineral which should be recognised as the property, as it is the heritage, of the nation.

It has been a matter of deep regret to me that my recent year's holding of an office which I highly value has been an even more troublous and anxious time than its predecessor. The country will never know, still less repay, its debt to this Society. It has pursued its way for the most part unheeded and unrecognised save by the few here and beyond the seas who know its worth. To-day its star, as is that of the industries it represents, is in the ascendant. In local Sections, as well as in membership, it continues to expand, and with this growth your Council are ever on the watch that its usefulness shall keep pace. Much depends upon the energy and enthusiasm with which the Sections perform their decentralised tasks of organising and stimulating progress. Much can only be done centrally, of which the conduct of the Journal is perhaps the most important example. I think you will agree with me, too, that the commencing volume of Reports upon the Progress of Applied Chemistry, which it is proposed to issue annually, is worthy of its subjects, despite the difficulties inseparable from production in the middle of the storm and stress of War. The industry owes much to those who originated and carried through the idea, and it is confidently hoped that the same note of progress which that volume of Reports expresses will be before long extended in the Journal, which it is intended shall not only provide a mirror of the progress of industrial chemistry, but a source of inspiration of new ideals.

It is not so long ago that the suggestion was seriously put forward that the successful investigation and utilisation of what one may call the higher branches of chemical knowledge were pursuits for which the Briton was not temperamentally fitted, and that they might in the world's interests be best left in the hands of a nation which has certainly carried them to a high degree of perfection. One cannot be surprised at the suggestion. To take the case of another industry—that of mechanical engineering—who, familiar with the Continental practices of thirty or forty years ago, could have imagined that to-day those standards compare favourably with our own? Another example of the truism that knowledge knows no frontiers.

So, too, one may imagine the scorn that may but three years ago have been expressed for a contemptible little Army of British technical chemists. As their brothers in France and Flanders, they have belied the criticism and have shown that our race is not incompetent to play its part without limitation or qualification in the tasks which confront mankind, and in which the science of applied chemistry must have an important share.

Professor H. LOUIS moved a vote of thanks to Dr. Carpenter for his address. Their President had shown by his career that a scientific man could be trusted to take charge of the economic and administrative work of a big organisation, a lesson which, he hoped, would not be lost sight of throughout the country.

It was fortunate that Dr. Carpenter had been guiding them through a period when the Society had been undergoing great developments both in its internal and external policy. Many changes had taken place during his presidency. The entire nation had at last awakened to the realisation of the value of the chemical industry, and it would be their task to see that the nation

did not in the future sink into its former apathy with regard to science.

He was entirely in agreement with Dr. Carpenter in his views in regard to education. It had been his own practice to advise every boy who came to him not only to secure the Matriculation qualification, but also to obtain practical knowledge by spending from six to twelve months in an engineering workshop. Whatever a lad was going to be in after life, the best practical education he could get was a few months spent in contact with the materials which he had to use and in association with the working men upon whom the future of the country so largely depended.

He believed that employers were glad to see the rise in wages, because they realised that they were most prosperous when wages were high.

He was in agreement with Dr. Carpenter, moreover, in his desire to see the resources of the Empire in regard to raw materials properly surveyed and recorded, and it was with great satisfaction that he hailed the decision of the Government to appoint an Imperial Bureau of Mineral resources.

The vote of thanks to the President was passed with acclamation.

REPORT OF COUNCIL.

The Report of Council was then presented as follows:—

During the year the Council has held 9 meetings, Accounts Committee 10, Publication Committee 24, Journal Extension Committee 2, Emergency Committee 5, Annual Reports Committee 4, Standardisation Committee 1, Catalogue Committee 2, International Catalogue Committee 2.

The number of Members now on the Register is 4429, as compared with 4059 last year. Since the last Annual Meeting, 521 Members have been elected, and the losses have been 151.

The losses by death amount to 53, viz.:—Hugh W. Aird, John Alden, John L. S. Allan, Rt. Hon. Lord Alerton, F.R.S., P. Carter Bell, Lyman M. Bourne, Henry Bowen, Dr. Harold de Haven Boyd, J. C. Butterfield, George S. Cooper, Dr. J. K. Crow, H. W. Davis, H. T. Deakin, Louis C. Deverell, Wm. Diestel, John V. Dupré, Prof. J. Ferguson, J. K. Forrest, E. G. Francis, Wm. Gemmell, R. Glegg, Harold E. Gresham, Allan T. Hall, C. E. Hanna, Major A. F. Hess, A. H. Hewitt, David Howard, Dr. J. H. Kastle, Edward Kay, Arthur G. Levy, Cuthbert P. Lewis, Ernest A. Lewis, John Lewis, Cyril D. McCourt, Ralph W. E. MacIvor, John Mackenzie, George Nightscales, Prof. John Oehler, S. Ollerenshaw, Harry Parker, Samuel Pope, Dr. Thos. Purdie, Sir Wm. Ramsay, K.C.B., Capt. Hubert W. Rawson, Sir Samuel W. Royse, Dr. J. H. Smith, Thomas W. Steven, R. M. Sutherland, C. Umney, Thos. U. Walton, Jas. W. Westmoreland, Lt.-Col. Thos. Wilton, Dr. Francis Wyatt.

David Howard, D.L., J.P., was President of the Society from 1886 to 1887, and Sir Wm. Ramsay, K.C.B., was President from 1903 to 1904.

The following members of the Society gave their lives to their country:—John L. S. Allan, Major Arthur F. Hess, 2nd Lt. Cuthbert P. Lewis, 2nd Lt. Cyril D. McCourt, Harry Parker, and Capt. Hubert W. H. Rawson.

Dr. Charles Carpenter's second year of office as President of the Society expires after the Annual General Meeting, and the Council has nominated Professor Henry Louis, of Newcastle-on-Tyne, as his successor in office.

Dr. Carpenter has been nominated a Vice-President, and to the vacancies caused by the retirement of four Vice-Presidents, Mr. John Gray,

Mr. A. R. Ling, Prof. R. F. Ruttan, and Mr. J. T. Wood have been nominated.

Four Ordinary Members retire from Council, and to fill the vacancies thus created, Messrs. A. G. Bloxam, W. J. Rees, Edwin Thompson, and Professor James Walker, F.R.S., have been nominated. The nominations being equal in number to the vacancies, there will be no ballot.

The following Chairmen of Local Sections retire:—W. J. Rees (Birmingham), Professor James Walker (Edinburgh), John Gray (Liverpool), A. R. Ling (London), J. H. Hoseason (Manchester), S. W. Wilder (New England). The following have been elected to succeed them:—Dr. R. S. Morrell, David B. Dott, A. T. Smith, Dr. Charles A. Keane, W. Thompson, and R. W. Neff.

The following changes have taken place among the Honorary Local Secretaries:—Dr. J. P. Longstaff (Edinburgh), appointed General Secretary of the Society, Dr. P. C. Mellhiney (New York) resigned after 6½ years' service, Mr. T. U. Walton (Sydney) deceased, were succeeded by Dr. A. Lauder, Dr. Allen Rogers, and Mr. S. E. Sibley respectively. The Council desires to express its thanks to the retiring officers for their services to the Society, and has conveyed to the relatives of the late Mr. Walton an expression of its sympathy and of its high appreciation of the work done by him in Sydney.

The Balance Sheet and Annual Statement of Accounts, which have already appeared in the Journal for 30th June, will be laid before the Meeting.

The Journal for 1916 contained 1274 pages of text, as compared with 1276 pages in 1915.

The Council has resolved to recommend that (1) the Annual Subscription for Membership of the Society should be raised from 25s. to 30s., commencing on 1st January, 1918, and (2) the life composition fees should be increased by £5 each. This recommendation will be submitted to the Meeting, and, if approved, to a Special General Meeting for confirmation.

The Meeting of Council in October was held at the Rooms of the Royal Society of Medicine in Wimpole Street, by the kind permission of the Council of that Society, in order that the Members might inspect the building and its general arrangements. The Meeting in November was held in the Board Room of the University of Leeds, by invitation of the authorities of the University, who also most hospitably entertained the Members present.

The Council has authorised the holding, two or three times a year, of Conferences of the Chairmen and Secretaries of the various Sections for the purposes of mutual assistance, and for helping forward the work of the Society. The first was held in Edinburgh during the last Annual Meeting, and subsequent meetings have been held in Leeds and London.

At the last Annual General Meeting, the Medal of the Society was presented to Mr. C. F. Cross, F.R.S. The Council has also formally conveyed to Mr. E. J. Bevan its high appreciation of the exceedingly valuable work he has done in collaboration with Mr. Cross.

Messrs. Cross and Bevan have placed at the disposal of the Society the sum of £20 as a prize for an essay on "The Interconnection of Economic Botany and Chemical Industry," and a further sum of £300 has been presented by their friend, Mr. T. P. Latham of Weybridge, as a grant towards research undertaken by such one of the competing essayists as may be judged to be of conspicuous ability. Essays are to be submitted to the Council of the Society not later than the close of the year 1917. Full particulars have already been published in the Journal.

The Council has forwarded to the Board of Trade the following resolution:—

"In view of the impossibility of deriving benefits from Patents during the War, the Council of the Society of Chemical Industry is of opinion that the payment of the annual fees upon Patents should be suspended during the War, and that the duration of British Patents should be extended for the same period."

The Publication Committee being aware that many matters of interest connected with Chemical Industry, such as Addresses or Papers given before other Societies, descriptions of new Plant, accounts of the establishment of new Industries, and so forth, are reported in local newspapers or are known to local members, have suggested to the Committee of each Section of the Society that it should appoint as "Corresponding Representative" a Member who would undertake the duty of looking out for such matters within the limits of the Section, and who would send in a Report which could be utilised for the purposes of the Journal. It is hoped that effect will be given to this arrangement.

The Council and Publication Committee have always had in view how best to improve the Journal so as to make it as interesting and as useful as possible to the Members of the Society, and they are glad to have received from time to time expressions of the high appreciation of the value it possesses in the estimation both of Chemists outside the Society and of those who are Members. They are anxious to take advantage of the marked increase of interest which, during the past two or three years, has been manifested in the Journal, to make it as efficient and up-to-date as is possible, and with this in view it has been decided to publish a separate part of the Journal to which the name "Review" is to be given, which shall deal with articles of general and industrial interest.

The appointment of an additional Editor to give the whole of his time to the work of the "Review" has been decided upon, and the Council have unanimously elected Dr. E. H. Tripp.

Dr. E. F. Armstrong and Prof. E. C. C. Baly, F.R.S., have been elected Members of the Publication Committee.

The Committee engaged in the preparation of a catalogue of chemical periodicals and patent literature, has prepared a list of over 5000 Journals, and is now engaged in consulting the various libraries in the United Kingdom with a view to ascertaining which Journals are to be found therein.

Dr. Rudolph Messel, F.R.S., has been re-appointed by the Council to serve on the governing body of the Imperial College of Science and Technology, for a further term of 4 years from 1st June last.

Mr. Tyrer continues to be the representative of the Society on the Executive of the National Physical Laboratory, and Mr. W. F. Reid is its representative on the General Board.

Steps are being taken for the formation of a Bristol and South Wales Section of the Society. A meeting was held at the University of Bristol some little time ago, which was attended by heads and representatives of local firms and others interested in the subject. Mr. Hedley occupied the chair, and the meeting was addressed by Mr. R. F. Easton, to whom is due the initiative in the matter, Prof. Francis, Mr. C. J. Waterfall, Dr. Rixon, and the Chairman, and it was resolved to form a Section of the Society in the district. Since then the Council has received a numerous signed petition in support of this resolution, and has given its approval.

The Council has pleasure in observing a considerably increased interest in the Society in Western Canada. Through the enthusiasm and energy of Mr. J. A. M. Dawson and Mr. J. H.

Hamilton, the question of the formation of a Canadian-Pacific Section of the Society has been brought forward. These gentlemen, after consultation with the officers of the Society in Canada, formed last autumn an Organising Committee consisting of Members of the Society resident in Alberta and British Columbia along with other prominent chemists. A circular letter was drawn up and sent to a number of chemists, technologists, and manufacturers. The result has been a considerable accession of new Members. The Council congratulates the promoters of this movement, and hopes to receive from them soon an application for the formation of a Canadian-Pacific Section.

Consideration is at present being given to a proposal for the formation of a Section of the Society in India.

In last year's Report it was stated that the Council had addressed to the Advisory Council for Scientific and Industrial Research a request for a grant in aid of a research on Cellulose to be carried out under the direction of Mr. Julius Huebner at the Municipal School of Technology, Manchester. This grant has since been received, the sum of £66 13s. 4d. being handed over for the period 1st August, 1916, to 31st March, 1917. The Council being satisfied with the usefulness of the work done, applied for a further grant of £100 for a period of 12 months from 1st April, 1917. This has also been received. The work being carried on is of a preliminary character to that which will be undertaken when more men and opportunities are available, and consists of a series of investigations as to (1) the methods of drying Cellulose in order to obtain exact weights, (2) the effect of drying at different temperatures and over different periods, and (3) the effect of moisture on the properties of raw, scoured, and bleached cotton yarn.

The Council has appointed four representatives of the Society, along with the Editor of the Journal, to confer with representatives of the Chemical Society on the subject of the abstracting of scientific papers with a view to seeing if some scheme could be devised to prevent overlapping. The matter is at present under consideration.

The Sub-Committee of the Board of Scientific Societies on the International Catalogue of Scientific literature submitted a series of questions to the Council regarding the extent of the use of the Catalogue made by scientific men, and asking for recommendations for possible improvement. The matter was remitted to a special Committee who have reported to the Board on the subject.

The Council has appointed two representatives to the Refractory Research and Standards Committee recently formed in order to consider the co-ordination of research work on refractory substances and to endeavour to secure joint action in carrying further the work of standardisation. An account of the first meeting of this Committee will be found in the Journal for 16th April last.

The Council issued last Autumn a series of questions to its Members on the subject of Industrial Alcohol. Since then, a Joint Committee of the Society of Chemical Industry, the Association of British Chemical Manufacturers, and the London Chamber of Commerce, has been formed to deal with the subject.

The approval of the Council has been given to the formation, in connection with the London Section of the Society, of a Committee of Experts in Industries connected with Sugar throughout the Empire to enquire into the question of providing a supply of sugar which should render the Empire independent of foreign sources of supply. Further particulars will be found in the Journal for 30th April, 1917.

The Council acknowledges with thanks several books presented to the Society's Library by Mr.

Tyrer, the Hon. Treasurer, and also valuable sets of the Journal of the Society from Mrs. Dickinson, of Brockley, and Mrs. Warden-White, of Laxham Gardens. It also records with pleasure the generous gift of Mr. Thos. Fairley, Hon. Secretary of the Yorkshire Section, of a complete set of the Society's Journal presented to the Edinburgh and East of Scotland Section to be coupled with the names of his former teachers in Edinburgh, Lord Playfair and Prof. Alex. Crum Brown.

Professor THOMAS TURNER, in moving the adoption of the report, said that the Council was to be congratulated on their work during the past year. The Society had done a considerable amount of useful work despite the difficulties arising from the war. The Journal had been maintained at a high, possibly a higher, standard of quality and usefulness, and the membership had substantially increased. The Report showed that the Council must have done a great deal of work for the benefit of the Society, and the meeting could, he thought, confidently adopt the report, which showed so much progress, and which was so full of encouragement.

Mr. E. ARDERN seconded the adoption. He thought the report was one upon which they could as a Society congratulate themselves. The Council had put in an abnormal amount of work which the members thoroughly appreciated.

The report was unanimously adopted.

TREASURER'S STATEMENT.

The PRESIDENT, in presenting the statement of accounts and balance sheet (see this Journal, 1917, pp. 617—618), expressed regret that Mr. Tyrer, their energetic Honorary Treasurer, was unable to present his financial statement in person, owing to the fact that he had to undergo an operation in respect of his eyes. He suggested that a message should be sent to Mr. Tyrer expressing the hope for his speedy and permanent recovery.

This was cordially agreed to.

Dr. ALFRED REE moved the adoption of the statement of the accounts. They had an excess of revenue over expenditure of nearly £900, which was partly due to the fact that their advertisements had yielded a larger amount and that the sales of the Journal had increased.

Mr. JOHN GRAY seconded the motion, which was unanimously approved.

INCREASE OF SUBSCRIPTION.

The CHAIRMAN said that for some time past proposals for increasing and extending the usefulness of the Journal and for developing its possibilities had been seriously considered by the Council and committees appointed for the purpose. He was glad to state, as the Report of Council had already done, that they were now in a position to announce a definite policy. They intended to maintain the present Journal in its entirety. Its form had been settled many years ago, and through times had changed the Journal remained unaltered. They desired to make the Journal in every way worthy of the Society: to make it eventually a standing weekly book of reference for all interested in chemical technology. They were not quite prepared for that later development; and what was being done now must be regarded as only a step towards that end. They proposed to publish a Journal which would deal with chemical industry in all its phases, recording not only the doings of the Society, but also reflecting what was happening throughout the world in the domain of applied chemistry. For that it would be necessary to build up a set of machinery parallel to that which was already running. They could not disturb the

present organisation; they wanted to add to it another one which would have its own Committee, and its own Editor; and that Editor would be assisted by a staff in the same manner that the present Editor was assisted by his staff of abstractors. The Council felt, too, that the Society's offices were inadequate, and that administration needed centralising. The Council had thought well to proceed with the experiment without waiting for the authority of the general meeting—which he hoped would be forthcoming—to increase the membership subscription. He hoped they would accept the views of the Council and agree with their proposal to increase the subscription. He moved: "The Council of the Society of Chemical Industry having considered the matter recommend and it is hereby resolved that:—

"(1) The yearly subscription for members of the Society shall from 1st January, 1918, be 30s. in place of 25s. as at present; and (2) that the amounts payable for life composition under By-law 11 shall each be increased by £5; and it is further also resolved that By-laws 10 and 11 be altered accordingly."

Mr. J. H. HOSEASON, in seconding the resolution, said that the need for the alteration was proved. Moreover, the purchasing power of the sovereign was not what it had formerly been; and it was not likely to return to its former level for a considerable time.

Professor TURNER suggested that the subscription should be raised to two guineas.

The PRESIDENT pointed out that the Council had considered that matter, but had come to the conclusion, having regard to the financial position of some of the members, that it was advisable not to ask for an amount that would give a surplus, but only sufficient for their needs.

Professor W. A. BONE suggested that the subscription should be made sufficient to cover the cost of the issue to the members of all the publications of the Society, including the Annual Reports, rather than that extra payments should be necessary.

Mr. E. HILL said that in his opinion the advertising side of the Journal was sadly neglected. The British manufacturer did not know how to advertise.

The PRESIDENT pointed out that the present arrangement with regard to the printing of the Journal, which also included the advertising, had been under consideration, but it was felt that for the present the better course would be to leave the matter undisturbed. As to the payment of an inclusive subscription covering all the publications of the Society, including the Reports, it had been finally decided by the Council to issue them at a separate fee, as they were not required by all members.

Mr. W. McD. MACKAY pointed out that the decennial index had been published in 1905, and since the war one had not been issued. Was there any intention to abandon the index?

The PRESIDENT said he was not aware that any announcement had been made that it was intended to discontinue this index. No decision of the kind had been come to. The question of the next issue would be considered.

Mr. L. P. WILSON drew attention to the arrangement whereby members with an income of not more than £150 were entitled to admittance without payment of the entrance fee.

The PRESIDENT stated that a fair number of members had taken advantage of that provision. The names of such members were not published and the whole matter was treated confidentially.

Dr. R. H. PICKARD said that it always seemed to him deplorable that there existed in London no central building at which the whole of the chemical societies might meet. Such a hall

existed in other countries. He hoped it would not be long before similar provision was made in the metropolis. He understood that the Chemical Society favoured such a scheme. Such a hall should in his opinion be common to all engaged in chemical science.

The PRESIDENT said that, without binding the Society, he thought there would be a readiness to consider with the Chemical Society any scheme for the provision of such a hall. The need was great. He was glad to hear that the Chemical Society was considering the matter.

The resolution was then put to the meeting and unanimously adopted.

APPOINTMENT OF AUDITORS.

On the motion of Mr. VLIES, seconded by Dr. CAIN, the auditors, Messrs. Feasey and Co., were reappointed.

VOTE OF THANKS.

On the motion of the PRESIDENT, seconded by Dr. A. HOLT, a vote of thanks was then passed to the authorities of the University for their generosity in allowing the Society the use of the lecture theatres, etc.

The meeting then adjourned, the members lunching at the Grand Hotel, by invitation of the Birmingham and Midland Section.

WEDNESDAY AFTERNOON.

The following papers were read :—

SOME OBSERVATIONS ON THE TEXTURE OF FIRECLAYS.

BY WALTER C. HANCOCK, B.A.(CANTAB.), F.I.C., AND W. E. KING, A.R.C.S.

The influence exerted by texture, or "grain-size," on the properties of refractory materials has now become generally recognised. It is obvious that the texture of raw or unburnt clay is quite different from that of the same material after firing and the methods of examining it in the one state are not applicable to it in the other. The determination of texture in the raw material is of course the simpler, since most clays can be thoroughly disintegrated by boiling with water, and separated into classes of grains the sizes of which lie within selected limits. In the case of the fired material there is no analogous method of procedure, and indeed it is not improbable that in that condition the individuality of the finer grains has disappeared owing to intimate coalescence or initial fusion. At present there seems to be no other possible method of determining the texture of fired clays except the microscopical examination of thin sections or at least of plane polished surfaces.

The experiments recorded below were made on a typical Stourbridge fireclay, and it seemed that a comparison of the properties of the raw and of the fired material might afford some link between the two states or indicate something of the mechanism of the physical changes that occur on firing.

Successive portions, amounting in all to about 1300 grams, or nearly 3lb., were subjected to elutriation in a Schoene apparatus and separated into the four usual grades designated as "clay substance," "silt," "fine sand," and "sand." By increasing the rate of water flowing through the apparatus this last fraction was subdivided into two grades the mean diameters of the particles in which were 0.04–0.10, and 0.1–0.2 mm. respectively. Incidentally the finest fraction was also subdivided in consequence of a comparison which was carried out between the Schoene

elutriation and a sedimentation process, which may be briefly outlined here.

The sedimentation process adopted was that suggested by Prof. T. B. Wood* for the mechanical analysis of soils. Ten grams of the disintegrated clay is thoroughly stirred with water in a beaker on which heights from the bottom are marked in centimetres. The liquid is brought up to the 8.5 cm. mark and allowed to stand 24 hours; at the end of that time the supernatant liquid, containing the finest particles in suspension, is drawn off, the residue at the bottom again worked up with water and brought to the 8.5 cm. mark and allowed to stand a further 24 hours. This procedure is continued till the supernatant liquid at the end of the specified time is clear. The finest particles drawn off in suspension may be allowed to settle and then be dried and weighed, or the various portions of liquid may be mixed, made up to a known volume and an aliquot part evaporated and weighed. The material left in the beaker is stirred with water, made up to the 10 cm. mark, and allowed to stand 100 seconds. The process is repeated till the liquid is free from suspended matter, the residue in the beaker being the coarsest fraction or "sand." All the material in suspension separated from the "sand" is allowed to settle and then stirred with water, made up to the 7.5 cm. mark and left to stand 12½ minutes: the material in suspension is designated "fine silt," and the residue which settles out at this stage, "silt." A comparison of the results obtained by the Schoene and the above sedimentation process are shown below; in each case 10 grams of dry clay was taken.

Size of particles. Diameters in mm.	Elutriation.	Sedimentation. (mean of 3 expts.)
0—0.002	4.6724 1.2511 } 2.1536 0.9025 } 3.1086	{ 0.5204 } 3.2484 { 2.7280 } 1.8314
0.002—0.010		
0.010—0.025		
0.025—0.040		4.8324
0.040—0.200		
	9.9346	9.9122

As mentioned above, the finest fraction obtained by elutriation was subdivided by the sedimentation process, five days being required to effect complete separation. Some of the liquid containing the finest particles in suspension was evaporated to dryness and the residue weighed, and in another portion the particles were allowed to settle, collected, dried, and weighed. The former procedure gave a product very seriously contaminated by the dissolved mineral matter in the tap-water used, as is clearly shown by the analyses in Table I., in which column No. 1 A represents the composition of the material allowed to settle out, and No. 1 B that obtained by evaporation. Even in the former case some contamination is indicated by the rather higher proportions of Fe₂O₃, CaO, and MgO, and by the fact that carbonates, chlorides, and sulphates accounted for the 7% deficiency shown in the analysis.

The extreme diameters of the particles in each group, confirmed also by microscopic measurements, were :—

Fraction No. 1	0—0.002 mm.
" No. 2	0.002—0.010 mm.
" No. 3	0.010—0.025 mm.
" No. 4	0.025—0.040 mm.
" No. 5	0.040—0.100 mm.
" No. 6	0.100—0.200 mm.

Table I. (p. 748) gives the chemical composition of the original clay and of the various fractions.

* J. Agric. Sci., I, Pt. 4, March, 1906.

TABLE I.

	No. 1 A.	No. 1 B.	No. 2.	No. 3.	No. 4.	No. 5.	No. 6.	Original clay.
SiO ₂	45.97	42.82	54.60	63.87	62.54	60.97	61.00	63.80
Al ₂ O ₃	25.65	7.46	28.76	23.79	24.45	25.30	24.10	23.16
Fe ₂ O ₃	2.44	1.39	2.57	2.20	2.28	1.79	2.38	0.67
CaO	5.64	27.82	1.11	1.28	1.05	1.02	1.18	0.85
MgO	1.26	1.70	0.39	0.35	0.28	0.32	0.22	0.11
K ₂ O	1.83	5.99	1.43	1.49	1.48	2.48	2.58	1.53
Loss on ignition ..	10.57	23.16	11.13	7.15	8.74	9.06	9.24	10.00

Rational analyses of the clay and of the various fractions were also made according to the process given in Lunge and Keane's "Technical Methods of Chemical Analysis," Vol. I., Pt. II., p. 587.

	Clay substance.	Quartz.	Felspar.
Fraction No. 1	90.0	7.4	2.6
" No. 2	79.2	26.6	4.2
" No. 3	66.4	30.1	1.5
" No. 4	65.3	32.3	2.4
" No. 5	66.1	31.2	2.7
" No. 6	65.9	30.5	3.6
Original clay	68.8	28.5	2.7

These tables show that the "clay substance," or material approximating to that represented by the "kaolinite formula," $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$, as might be expected, composes the bulk of the finest grained fraction and the quartz tends to accumulate in the coarser fractions.

Physical properties. Measurements of some of the physical properties of the various fractions were also made.

Plasticity.—A quantity of each fraction was pugged up by hand with water and submitted to a "plasticity test" by means of a Vicat needle. It was found necessary to modify the time, and in place of the usual five minutes a period of a quarter of a minute was substituted; hence the results are only relative with regard to the series in question. From the mean results of a number of experiments, the following "plasticity numbers" were obtained:—

Original clay	100
Fraction No. 1	123
" No. 2	139
" No. 3	113
" No. 4	98
" No. 5	94
" No. 6	100

The amounts of water in the various test-pieces were adjusted so that the 300-grm. needle penetrated a depth of 5 cm. in 15 seconds; the test-pieces were then dried at 105° C. and the water present calculated on 100 parts of dry clay. The figures in the above table show the ratios of these amounts of water, taking that in the original clay as 100.

Air- and fire-shrinkage.—A number of test-pieces, 10 cm. by 1 cm. by 1 cm., were moulded and allowed to dry. Some test-pieces from each fraction were allowed to dry very slowly in a covered vessel in order to decrease the tendency to warp, which was very noticeable in those of the fine-grained material. When all the bricks had become constant in weight, they were dried in an air-oven at 105° C. for 2½ hours to drive off all the hygroscopic water and were afterwards fired to 1200° C.

The following table shows the shrinkage and loss of weight of the test-pieces under these conditions:—

TABLE III.

	Water at time of moulding.	Loss of weight.		% Shrinkage.
		Air.	105° C.	
Original clay	24.0	17.0	19.4	5.7
Fraction No. 1 ..	22.4	16.9	18.3	—
" No. 2 ..	27.0	20.0	21.2	5.8
" No. 3 ..	19.5	15.9	16.6	4.0
" No. 4 ..	18.2	14.3	15.4	4.2
" No. 5 ..	19.2	15.2	16.1	4.3
" No. 6 ..	20.7	16.1	17.7	4.7

It was not possible to obtain readings for the shrinkage of the bricks of fraction No. 1, owing to excessive warping. It is interesting to note that the air-shrinkage appears to have a minimum value in test-pieces made from fraction No. 3.

The following table shows the results obtained on firing to 1200° C.

TABLE IV.

	% Loss of weight at		Diff.	% Shrinkage at		Diff.
	105° C.	1200° C.		105° C.	1200° C.	
Original clay ..	19.4	27.3	7.9	5.7	8.8	3.1
Fraction No. 2 ..	21.2	29.5	8.3	5.9	12.4	6.5
" No. 3 ..	16.6	24.7	8.0	4.0	7.2	3.2
" No. 4 ..	15.4	23.7	8.3	4.2	8.6	4.4
" No. 5 ..	16.1	24.3	8.2	4.3	9.0	4.7
" No. 6 ..	17.7	25.8	8.2	4.8	9.6	4.8

These figures also show that the minimum shrinkage is obtained with test-pieces composed of grains from fraction No. 3.

Conclusion.—Of course from a set of observations on a single clay, general conclusions cannot be drawn, but we think that the results obtained may not be without interest. The experiments have involved a very much larger amount of work than might at first sight appear. They seem to confirm the distribution of the "clay substance" and quartz which one would expect to find among the various fractions. Fraction No. 2 (0.002–0.010 mm.) differs markedly from the others; it takes the highest amount of water for moulding, and gives the largest air and fire-shrinkage, which have minimum values in the fraction with the next larger grains (0.010–0.025 mm.). If points such as these are substantiated by later observations, they should be of some practical value as a guide to the size of grain which should be selected in materials in order to ensure certain physical properties. Further work on these lines is in hand.

The experimental work recorded has been carried out in the refractory materials laboratory in the Department of Chemical Technology of the

Imperial College of Science and Technology, South Kensington, and our thanks are due to Professor W. A. Bone, D.Sc., F.R.S., for the facilities he has afforded us.

DISCUSSION.

The CHAIRMAN said that scientific methods were being adopted by most of the British manufacturers of refractories. The old method was simply to take the clay, and after a due amount of weathering it was mixed with a certain amount of "grog" and that was the end of it. That had been the English manufacturer's idea of building up refractory material for general use. The German method was to find what the ultimate composition of their clay should be, and if it were deficient in the qualities required they fortified it in the light of experiment and experience. In that way they were able to compete with goods in this country, although they did not possess all the materials necessary to produce them. The final article they produced was better for practical work than anything the British manufacturer had been able, for a long time, to produce. We were now altering our methods, and producing something that was better than before, though not yet equal to that made by the Germans.

Mr. A. G. ROBERTS asked for further information in relation to the percentages as stated in cols. No. 1 A and No. 1 B.

Dr. J. T. DUNN drew attention to the variations in the analyses in the two columns mentioned, particularly in relation to silica and alumina, and pointed out that the samples commencing with No. 3 up to 6 differed little from the original clay with regard to original constituents; but the amount of iron was considerably greater than that in the original clay. The figures appeared difficult to explain. It would have been interesting if Mr. Hancock had ascertained the relative refractory characters of those portions of the clay as compared with the original.

Mr. ROBERTS said that adsorption led to difficulties in separating certain clays; by the use of distilled water it might be possible to overcome many difficulties.

Mr. J. W. HINCULEY expressed the hope that the author would later on devote his attention to the elucidation of the problem of plasticity. It was important to define what was meant by "working condition." There was a great tendency to work the clay with too much water, and in a too plastic state.

Mr. HANCOCK, in reply, said he used the term "working condition" in the sense that there was a kind of "feel" about well-tempered clays which was difficult to define. It was that feeling, or sensitiveness, which afforded guidance to the worker. Regarding the two columns to which reference had been made by Mr. Roberts, the one was the analyses of the fine material separated; the second column gave the partial analyses when evaporated down. The use of distilled water would get over many difficulties, but it was not easy to arrange for the necessary large supplies. Regarding Dr. Dunn's observations, he was aware that the composition of the first fraction did not exactly represent the composition of china clay; but the ratio between silica and alumina in that fraction was nearer to that found in china clay than it was in the original clay itself. The presence of iron showed the disturbing effect arising from the use of tap water. The iron content was high, owing to the fact that a certain amount of iron was collected from the iron vessel used. His own experience confirmed that statement. He hoped, later on, to be able to extend the work to other physical determinations and particularly with regard to the refractoriness of the samples mentioned by Dr. Dunn.

Mr. BUTTERFIELD asked if the author held that the finer parts which were separated existed in that degree of fineness in the original firebrick, or did he think they were produced from the more fragile constituents of the firebrick. It seemed to him that this method of disintegration amounted merely to measuring the brittleness of certain parts of the firebrick as burnt and it might not have much bearing on their refractory character.

Mr. HANCOCK said that if the original clay, as mined, were treated with water, it could be disintegrated satisfactorily. Using ordinary care he did not think the state of subdivision of the constituent parts of the clay was materially different from that in the particles produced in the segregation of the rock. His contention was that they had no means of disintegrating firebrick in the same way.

CHEMICAL LABORATORY PORCELAIN.

BY HENRY WATKIN.

Introduction.

The first attempts to make porcelain in Europe were undoubtedly in imitation of the Chinese porcelain imported into Europe by the Dutch, English, and French East India Companies about 1673.

Its beautiful whiteness, its thinness, its translucency, its close vitreous fracture, apart from and also in conjunction with its decoration, at once appealed to and obtained the admiration and emulation of the Europeans.

The story of the struggle in the attempt to reproduce it is not within the scope of this paper, but suffice it to say, that it was accomplished in Germany by Bottcher about 1706—1718, and in England by Cookworthy of Plymouth about 1767.

The one factory continued for the reason that not only were the products excellent, but the financial success was not the main object, while the other had to bear its own losses and though there was considerable promise of success, the financial aspect of the undertaking was a complete failure. It is well, then, at the outset to note that we do not owe the origin of the porcelain to the continental potters but to the Chinese.

Chinese porcelain being at that time the only translucent pottery in existence, there can be no wonder about the admiration it called forth.
